public. We have only to say that the entry forms of both Salon and Royal can be had by sending a penny stamp to the "B.J.," or the Salon entry form is, of course, obtainable from Mr. Reginald Craigie, 5A, Pall Mall East, London, S.W.

### **The Use of Fogged Plates.**

Professor R. W. Wood, of John Hopkins University, in dealing with the photography of faint spectra, advocates the use of plates that have received a preliminary slight fogging, just sufficient to take the plate to the end of the curve of under-exposure. This expedient is not exactly new, but it is one that is very seldom tried. The idea of deliberately fogging the plate is repugnant to most photographers, and in any case it can easily be overdone. Still, if it is as successful as has been stated it is a simple thing to try when very faint objects have to be photographed. Further than this, if it is an advantageous expedient with faint objects it might also be a useful one in very high speed camera work. There is an opening for careful experiment both as regards the best methods of fogging the plate and as to the class of work with which the use of such plates is advantageous.

### **Advantages of the Focal-Plane Shutter.**

A couple of illustrations in the "Photographic Monthly" illustrate in a striking manner the advantage that the focal-plane shutter possesses over the more common lens shutter in the matter of efficiency. Two photographs of a waterfall are given, one in the reproduction showing every indication of under-exposure, while the other suggests a full, or perhaps slightly excessive, exposure. In point of fact, however, the first received an exposure of about 1-30 sec. with a lens shutter, and the other 1-200 sec. with a focal-plane. We take it that both speeds are nominal, and that probably the focal-plane exposure was rather longer than the 1-200 sec., but in any case it must have been a much shorter exposure than the other, for it has preserved all the detail in the falling water. At the same time, the dark rocks are quite as fully exposed, if not more so, and this effect can only have been due to the high efficiency of the focal-plane shutter. Probably the efficiency of this was near unity, while that of the lens shutter was only about one-third, and if we discount the marking of the former shutter it is possible that the actual exposure was much the same in the two cases. The difference in the result is, however, very striking indeed.

### **Reversed Carbon Portraits.**

While there is no difficulty in making a double transfer carbon print from either the flexible temporary support or a prepared opal support, it is undoubtedly a little quicker, and for a less experienced worker easier also, to make a single transfer, and therefore, if an ordinary negative be used, reversed carbon print. How far it is wise or even legitimate to send out such prints is an interesting question, and one that must be answered in each individual case. Sometimes the details of the dress or the wearing of eye-glasses or some facial peculiarity enable the reversal to be at once detected and so prohibit its use. In other cases, perhaps most readily in children's portraits, lateral reversal passes without notice. In a case which quite recently came to our notice it resulted in a further order. Some portraits of a friend had been made by a photographer, and double transfer prints were sent and greatly admired. A single transfer print of one position was given to a mutual friend, and seen later by the sitter's mother was mistaken for another position and declared to be a better picture than any of the others. That this should happen in the case of a reversed portrait was not a little curious,

for while such a reversed print shows sitters the same appearance as they are accustomed to in their mirror, undoubtedly gives to any other face an unfamiliar aspect unless the features are very regular and symmetrical, unless the portrait is a profile.

### **Photography as an Aid to Measuring Buildings.**

Architectural students frequently require measurements of buildings in the case of the larger structures but are often by no means easy to oblige. By selecting a time when the front of one of the cathedrals is covered with scaffolding this measuring does not present insuperable difficulties, though assistance with the measuring tape is usually necessary. If no such scaffolding is available the work must be done by means of ladders, often at considerable bodily risk, though the method of lowering a rope marked distinctly in 3ft. lengths, sometimes be useful, distances being set off on a rough sketch elevation by a colleague situated on the ground and at some little distance. Some recent experiments have shown us that considerable use may be made of photography in this direction, provided a few special points are attended to. First, a view-point should be chosen as nearly as possible opposite the centre of the frontage, and in every case the axis of the lens must be absolutely at right angles to the frontage. On some of the building a scale must be made by marking vertical lines at a distance of, say, 3 feet apart. If it is desirable to mark the building in this way four or five white rods or laths may be set on the pavement in vertical position and placed a yard apart. Measurement on the one plane only can be made, though if there are two parallel planes the one photograph may be utilized for measurements on both planes, provided a scale is attached to each plane. The depth of a recess or the extent of a projection cannot be measured from the photograph.

### **The Camera and Lens.**

The camera used for such work should have the movements and capabilities usually required in an instrument for architectural photography. Ample rise of front together with bellows nearly square as possible is one of the main points. A cross front is in some cases an advantage, for where a view-point is somewhat to the left or the right of the centre of the frontage line the image of the building will be centred on the plate without difficulty or waste. The axis of the lens must point at right angles to the front of the building, and if no cross front is fitted then a wide angled lens will probably be needed to get the required amount in. The choice of lens is also an important matter and naturally a non-distorting objective must be employed. Not only will the single landscape lens be esteemed, but a symmetrical objective, of either the rectilinear form or the anastigmatic, will preferably be chosen. The fine covering power of many of the modern flat field lenses marks them out as being eminently suitable.

### **The Acid Fixing-Bath.**

The recent spell of hot weather, which may at any time during the next few months be repeated, has brought usual troubles for the photographer, and it is a very tribute to the quality of our plates and papers that such a disaster is so comparatively rare. Fifteen years ago when owing to the softness of the emulsions, it was scarcely possible to develop a dry plate with soft or distilled water and even when hard water was used in warm weather the danger of frilling was imminent, it was a frequent practice to mix a fixing bath containing chrome and

It is somewhat rare to find any other fixing than one of plain hypo, especially where the non-developers are employed—or where an ample quantity of sulphite is used in the pyro developer and the yellowness of the negatives is not only objected to but possibly preferred. Quite apart from the merits of fixing bath as a preventive of stain is its value in hardening the gelatine film, thus enabling the plate to be handled after fixing and to be washed a sufficient time with cotton wool after washing without risk of damage.

The use of the ordinary bisulphite of soda gives advantages with the minimum of trouble, for a pound of sulphite in a Winchester of warm water gives a stock solution that will keep. If one ounce of this is added to one of the usual one in four hypo solution and the acid fixing bath is at hand.

#### ACID DIAMIDOPHENOL DEVELOPER.

On this page we commence an abstract from M. Balagny's book on "Diamidophenol en Liqueur Acide," which contains a great deal of useful information upon a developer that is at present rather neglected in this country.

It will be noticed that Formula IIA has a certain resemblance to the one given in the "B.J. Almanac," on page 13, the principal difference being that where M. Balagny uses acid bisulphite solution the "Almanac" uses which is that of Mr. Welborne Piper, advocates sodium metabisulphite in very much larger relative proportions. In both cases the sulphite and the acid salt are in one solution, which solution has remarkable properties and also certain peculiarities described by Balagny. Our experience of the acid amidol or phenol developer has been confined to the formula in the "Almanac," and it appears that the neutral solution there described has exactly the same results as M. Balagny's S solution.

Acid developing formulæ have been in use, especially on the Continent, for a very long time, and it is that up to the present they have not appeared in the instructions issued by the various English plate and camera makers. The old formula with plain sulphite is still in use, and while this forms an excellent developer its ingredients are quite freshly mixed, it has many disadvantages which deter photographers from making use of it. A stock solution of sulphite, for example, is kept for more than a very short time, and the necessity of making up fresh solution is a great trouble. This trouble vanishes if we substitute the S or the neutral sulphite solution, for the plain acid amidol the mixed developer can then be used for a number of plates without fear of stain or discoloration.

It should be noted that the "Almanac" formula is for amidol, and M. Balagny's formulæ for phenol, which is not, perhaps, exactly the same as the latter salt is now easily obtainable in this country and in trying M. Balagny's formulæ we suggest that it could be as well to use it. It keeps much better than amidol, according to our experience, and the emulsion is generally quite white, and will keep so for a long time.

A somewhat important part of M. Balagny's book is devoted to dealing with the functions of the various ingredients of the developer. It is, perhaps, too often contended that amidol is a strictly one-formula developer, and that of varying the proportions of the sulphite are reserved. It will be seen that M. Balagny gains control by varying the amount of acid sulphite, and, however, appears that the acid sulphite must

have a rather more powerful restraining action than the metabisulphite, for we have not noticed that the "Almanac" formula is unduly restrained, even though it contains a very large proportion of the acid compound. Apparently the restraining power of the metabisulphite varies greatly with different developers, for its effect with pyro seems to be greater than with amidol, and very much greater with hydroquinone than with pyro.

Many workers use amidol for bromide prints, but very few use it for negatives. We have, however, found the acid formula excellent for work with negatives, whether in dishes or tanks be used.

#### PRACTICAL HINTS ON FRAMING PHOTOGRAPHS AND ENGRAVINGS.

It may seem a matter of supererogation to say anything on the subject of framing pictures, but when one notices the way that some of this work is done some remarks seem occasionally called for. The object of framing a photograph, or an engraving, is twofold—viz., to show the picture off under the most favourable conditions, and to protect it from mechanical injury, as well as to preserve it from injurious influences. With regard to the first point, it is not our intention in the present article to say anything, since much has been written on the subject during the past few years, and, after all has been said, choice depends largely upon personal opinion and individual taste. We may, however, deal with several points having reference to the mechanical side of framing.

Many photographers at the present time style themselves picture-frame makers and picture framers, but, judging from the way that some of this work is frequently done, there is no question that some of them do not understand this branch of their business, or, if they do, they carry it out in a manner so perfunctory as to be almost reprehensible. It is by no means uncommon to see—in the case, say, of enlargements that have been hung for a year or two over the fireplace, or other part of a room that is lighted by gas—that the corners of the mounts have become discoloured. This is due to dust, or, perhaps, smoke, gaining access between it and the glass. Again, the whites of some bromide enlargements, in a year or two, become of a decided yellow tint under similar conditions. It is tolerably well known that the fumes from burning gas have a deleterious action on all silver pictures, and in many instances bromide enlargements do not receive such care in their production that they will resist for long such destructive influences. That being the case, they ought to receive all the protection that a frame should afford them. This is a point that is too frequently neglected by the photographer by whom they may have been produced, even when he does the framing himself.

The most important thing to be considered in framing photographs or engravings is to ensure their being made perfectly dust- as well as air-tight in the frames. It goes without saying that if the picture is sealed up air-tight it must also be proof against dust and smoke, or other injurious fumes. This end is always ensured when the work is done by skilled and conscientious picture-framers, such, for example, as make a specialty of dealing with valuable engravings. They always employ a much stouter and better fitting backboard than is usual with photographers. Backboards can be had of any thickness, from eight to twelve, or more, cuts to the three-inch plank. The backboards supplied with some of the cheaper kinds of frames are so very thin that they have not sufficient stability to press the mount in contact with the glass, except just where they are bradded into the frame. Moreover, they are often in several pieces. In the better class of frames, as just mentioned, the backs are much thicker, and instead

of being in several pieces are all glued together, then neatly planed up, and bevelled at the edges where the brads are to go. With such backboards it is a very easy matter to seal up the picture perfectly air-tight.

A recommended method of framing is, therefore, as follows:—In the first place the glass must be thoroughly cleaned and polished on both sides. Whiting and water is as good as anything for the purpose. When cleansed the glass should be examined for air bubbles, and if any of large size are seen it had better be discarded altogether. If not, care should be taken that the picture be placed in the frame so that the bubbles are before the least important part of the picture, say the figure portion, if it be a portrait. If they come before the face they will show very conspicuously and thus considerably mar the picture. The glass should now be papered in the rabbet of the frame. This is done as follows:—Enough strips of paper (good newspaper will do), about three-quarters or an inch wide, are cut to reach round the frame. They are then coated on one side with flour, or starch paste, laid neatly so that one edge lies on the glass to nearly the width of the rabbet, and the other on the side of the frame, and allowed to dry. When this is done, no dust can get to the mount from the front. It is a good plan before laying in the paper to rub a little paste round the rabbet to fill up the pores of the wood, better adhesion and greater ease in working being obtained. The glass is now examined to see if any paste has been pressed out from the paper, for, if such is the case, it must be cleaned off.

The frame is then well dusted out, and the gilt flat, if one is used, is laid in, and on that is placed the picture. The backboard is then dusted with a brush to remove dust of any kind, for with unplanned wood there is a likelihood that adhering sawdust would get between the glass and the picture. It is then bradded in temporarily with two or three brads on either side. The frame is then turned over to see if any dust or particles of wood have got imprisoned between the glass and the picture. This having been seen to, the backboard is permanently secured with brads. The

best for this purpose are known as "fine cut picture brads" which may be had from most of the large ironmongers. They have, however, been largely superseded by thin wire nails. When driving in the brads something solid, such as a weight or hammer-head, should be pressed against the side of the frame to drive against, in order to prevent joints at the corners being "started."

We have now framed our picture in such a way that dust, smoke, or injurious vapours can get at it or mount from the front, and what has now to be done to make the work complete is to prevent them from gaining access from the back. That is done by papering in the backboard. Some do this by pasting strips of paper round the backboard and the frame, and often so clumsily as to give the work a slovenly and unworkmanlike appearance. The best way of sealing the back is to cover entirely with a stout sheet of brown paper which is secured only to the frame itself, and not attached to the backboard at all. The best plan is to cut the paper a little smaller—three-quarters of an inch, or so—than the outside of the frame. The paper is then laid on the workbench thoroughly and evenly wetted with a sponge well charged with water. It is then allowed to lie for a few minutes to allow it to fully expand. The back of the frame (only then coated with a cement—glue is best for the purpose) the paper laid on, well pressed in contact all round the frame, and allowed to dry. The paper, although it looks slack while wet, will be as tight as a drumhead when dry. The advantages of this method of backing over former are that the work looks neater, that a rough unsightly backboard is hidden, and that if at any time the board shrinks or cracks, as many do when hung in a wall place, it is of little moment, as the picture remains unaffected all the same. It may be well to point out to the novice that the brown paper used for the purpose should be thick and of the best quality, so as to resist the shrinkage as it dries. If a very common paper is used the probability is that it will split right across length or width on drying.

## THE PHOTOGRAPHIC CONVENTION AT BRUSSELS

FOLLOWING on the notes in last week's issue, made during the first three days of the Convention week, we may describe the whole of the Convention proceedings as certainly as enjoyable as any of recent years. The attendance is sufficiently evidenced by the group taken on the Wednesday afternoon, which is presented as a supplement with the present issue of the "B.J.," although the membership of the Convention is never fully represented in the official group.

Particular interest was taken in the fine exhibition of portraiture arranged by the Platinotype Company, which, as in previous years, has not only given conventioners an opportunity of inspecting some really magnificent photographic work, but has also regularly provided an object lesson in hanging and display, to say nothing of the essential object of the collection, namely, the display of the merits of the company's various platinotype papers. This year the collection includes the work of Messrs. Walton, Adams and Sons of Reading, Messrs. Vandyk of Buckingham Palace Road, Mr. J. Craig Annan of Glasgow, Messrs. Alfred Ellis and Walery of Baker Street, Messrs. J. Weston and Sons, Messrs. Drummond Young and Watson of Edinburgh, Edwin Hadley, Nottingham, and Histed, Baker Street. Some of the fine portraiture by Godensky of Philadelphia, was also shown, as well as a number of reproductions of paintings by A. Vignais of Paris. Among all these the delicate and artistic work of Messrs. Drummond Young, in the way of platinotypes coloured to a slight extent, is particu-

larly worthy of notice, as is also a number of landscapes in various colours by a lady, with platinotype as a faint photographic basis.

The demonstrations of Mr. C. L. Burdick attracted a deal of attention, and drew prominence to the remarkable facility provided by the aerograph. The exhibit of the K. Company took the form of handsome prints and enlargements on the firm's many brands of printing-out and development papers. Messrs. Watson, who with the firm of Carlisle completed the trade exhibition, showed their various cameras and such recent introductions as the walking-stick finder level. They also exhibited a number of photographs illustrating the properties of the holostigmat series of lenses.

So far as concerned the programme for the week, submitted to that reported in our last issue, it may be said that despite the many other attractions in Brussels the evening meetings have not been so well attended for a number of years. The more popular character of the fixtures is no doubt responsible for this, and though the result may be considered satisfactory in this respect the Convention cannot afford to lose sight of the importance of maintaining the more serious and scientific character which many of its papers possessed in the past. It was this which secured for it its present position, and to permanently abandon such policy as that must necessarily lead to the destruction of the Convention as an annual and useful function in the photographic world. Thursday evening's

took the form of a lantern display, first of Belgian scenes members of the Association Belge, which were explained in French by M. Vanderkindere. This was succeeded by a lantern display by M. Marissiaux, which provided a form of lantern entertainment new to English audiences. Contenting himself with a few comments on each picture M. Marissiaux led his hearers through the Venetian by-ways and into the churches of the city. His pictures followed his comments with a smoothness which is rarely found in lantern lectures in this country. The case of many of the interiors of the churches the effect of M. Marissiaux's fine transparencies was enhanced by a vocal organ accompaniment, the whole performance being expertly stage-managed. It remains to be seen whether society entertainers, a good sprinkling of whom were among this year's conventioners, will be taking steps to introduce a similar form of entertainment among their winter fixtures.

The Convention dinner was held at the Grand Hotel, Boulevard Anspach, with the President, Sir E. Cecil Hertslet, in the chair. The loyal toasts of the British and Belgian nations were proposed by the President, and heartily received.

"The Convention," proposed by Mr. E. J. Humphery (Past-President), was responded to by Mr. F. A. Bridge, who made an eloquent reference to the help given by Commandant Van Bever by Mr. Vanderkindere, associating their names with the motto of "The Association Belge de Photographie," and "The Revue Artistique et Littéraire." Both gentlemen responded.

The President was proposed by Prof. C. H. Bothamley (Past-President) with his usual humour, and was responded to in French expressing the greatest possible satisfaction with the results of the Convention to Belgium.

Mr. H. Snowden Ward proposed "The Ladies," on whose behalf the Rev. C. Hertslet replied most suitably; and Mr. E. P. Cembrano (Past-President) proposed "The Visitors." In response, M. Edouard Séve, Consul-General for Belgium in London, and, referred most eloquently to the long-standing friendship between the two countries, and expressed a hope that mis-

understandings which had arisen through exaggeration and misapprehension would soon be removed as the result of examination of the real facts.

The excursion to Antwerp, which took place on Friday, was perhaps the most interesting of the week, and the reception given by the Burgomaster in the Hotel de Ville deserved all the nice things gracefully said of it by the President. A demonstrative reception was in turn extended to M. Alphonse Hertogs, who was accompanied by his colleagues MM. Albrecht and Strauss, after which the conventioners dispersed to visit the cathedral, churches, and museums of Antwerp, reassembled at lunch at the Grand Hotel, and, after a trip on the Scheldt, once more met at the Zoological Gardens to enjoy the hospitality of the President and Lady Hertslet.

Mr. Martin Duncan's lecture in the evening, on the applications of the cinematograph and the Autochrome plate in nature photography, was exceedingly well received. Saturday saw the Convention making its last excursion to Malines, and though a number of visitors are no doubt scattered over Belgium, or are returning via Paris, the official programme of the week ended with this latter excursion.

The reception given to the Convention by the municipalities of Ghent and Antwerp were among the most agreeable recollections which visitors will have carried away with them. Among those who attended the "At Home" of Sir Cecil and Lady Hertslet on the Friday afternoon were General van Sprang, Gouverneur de la position fortifiée of Antwerp, and M. L. Verhoogen, Capitaine-commandant du Génie. Sir Arthur Hardinge, K.C.B., was also to have been present, but missed his train.

The Saturday excursion to Malines was very largely attended, and the luncheon provided a good chance for speeches of thanks and farewell (or rather, au revoir). The President took the opportunity of emphasising the great indebtedness of the Convention to the Burgomasters and municipalities of Antwerp, Ghent, and Malines, for their hearty welcomes and civic hospitality.

## SLOW-BURNING MAGNESIUM POWDERS.

Dr. Franz Novak, in the current issue of "Photographische Korrespondenz," gives the results of measurements of flashlight powders, which continue the experiments made a year ago, and recorded in the "B.J." of August 23, 1907, page 632, and "The British Journal" Almanac, 1908, page 599. His present paper relates to the preparation and properties of slow-burning powders, placed on the market as time-lights.—Eds. "B.J."]

The photographic activity of the under-mentioned mixtures was measured by means of the Eder tube photometer, gelatinoid of silver dry-plates being exposed to the various lights. The chemical strength of the light is expressed in candle-metre-seconds (H.M.S.), the Hefner amyl-acetate lamp being taken as unit.\*

The powder in all these experiments was six metres from the photometer, and was arranged in small capsules placed on an asbestos plate. The powder was fired by means of a electric touch-paper. For this purpose filter-paper was dipped in a warm solution of one part potass nitrate in two parts of water, and the paper hung up to dry. Three ground-glass plates were placed in front of the sensitometer in order to reduce the strength of the light. The powder burnt contained roughly a charge of 1 gm. of magnesium. In estimating the rate of combustion 5 gms. of the slow-burning powder were used. These latter were placed in capsules made of parchment of a diameter of 1 cm., closed below by cork, and provided on the upper side with a length of touch-paper. The time of

combustion was ascertained with a chronograph. The following table gives the results obtained:—

Combustion Powder.	Relative chemical strength on dry plates in candle-metre-seconds (H.M.S.) of mixtures containing 1 gm. of magnesium.	Rapidity or combustion in seconds of 5 gms. of the powder.
1g Magnesium .....	160,000 .....	5.5
0.7g Ceric nitrate (anhydrous) .....		
0.3g Strontium carbonate .....		
1g Magnesium .....	140,000 .....	4.5
0.6g Ceric nitrate (anhydrous) .....		
0.4g Strontium carbonate .....		
1g Magnesium .....	125,500 .....	4.8
0.3g Ceric nitrate (anhydrous) .....		
0.5g Strontium carbonate .....		
1g Magnesium .....	140,000 .....	1.3
0.6g Strontium nitrate .....		
0.4g Strontium carbonate .....		
1g Magnesium .....	130,000 .....	4.3
0.4g Strontium nitrate .....		
0.6g Strontium carbonate .....		
1g Magnesium .....	86,500 .....	11.2
1g Magnesium carbonate .....		
1g Magnesium .....		
1g Calcium carbonate.....	67,500 .....	25.0

Comparing the slow-combustion mixtures, prepared according

\*Candle-metre-second (H.M.S.) is the chemical strength of a Hefner amyl-lamp at one metre distance acting for one second.

to the above formulæ, the best is seen to be that consisting of 1 gm. magnesium, .7 gm. ceric nitrate, and .3 gm. strontium carbonate. The mixture of magnesium 1 gm., strontium nitrate .4 gm., and strontium carbonate .6 gm., is a weaker light, and burns somewhat quicker than the mixture just mentioned; it is, however, an excellent preparation. The mixtures containing magnesium and calcium carbonate give very much less light; and in regard to those in which calcium carbonate occurs it should be mentioned that the combustion takes place irregularly,

and they cannot be recommended for practical use. The smallest production of smoke occurs in the case of mixture containing ceric nitrate and strontium carbonate, greater amount being produced in those containing strontium nitrate and strontium carbonate. If a portion of the magnesium is replaced by aluminium powder a reduction in the amount of smoke produced is usually noticed, but further experiments in the use of aluminium in slow-burning powders are still in progress.

FRANZ NOVAK.

## DEVELOPMENT WITH DIAMIDOPHENOL IN ACID SOLUTION.

[The use of diamidophenol in conjunction with sodium bisulphite has found an enthusiastic champion in M. G. Balagny, whose published papers on the subject are scattered through the French photographic journals for the past few years. A medal was recently awarded M. Balagny for his method of using diamidophenol for obtaining warm tones on gelatino-chloride plates, but for negatives of both time and instantaneous exposures, bromide papers, as well as lantern-slides, the properties of the diamidophenol formula are described by him in terms which are perhaps at times somewhat too glowing, but which, nevertheless, are worthy of attention, particularly by users of Autochrome plates, in view of the experiments made by M. Charles Simmen on the use of the same developer for the development of Autochromes in a red light. The following notes, therefore, which are abridged from M. Balagny's recent "Monographie du Diamidophenol en Liqueur Acide," published by MM. Gauthier Villars, may be here translated as an abstract of the chief technical advice which the author has to give.—Eps. "B.J."]

DIAMIDOPHENOL has an acid reaction, but 1 gramme dissolved in 200 ccs. of water with 6 grammes of anhydrous sulphite of soda added gives a solution which is slightly alkaline. While the alkaline form of the developer may be recommended certainly for snapshot work, and even for studio portraits, it is far less suitable for the many forms of time exposure. It is impossible to hold back the action which takes place as soon as the plate is placed in the solution. Everything appears at once—shadow, detail, and high-lights. The high-lights and shadows are obtained together, when it would frequently be convenient that only one or the other should be obtained first. It was for this reason that diamidophenol was first abandoned. It was recognised as one of the most energetic of developers—in the words of Dr. Eder, "no known developing substance produces the image with a shorter exposure"—Dr. Just attributing to amidol and sulphite a developing power greater than that of metol-sulphite and potass carbonate, eikonogen-sulphite and soda, or even pyro-sulphite and potass carbonate.

### Controlling the Power of Diamidophenol.

It was, therefore, of interest to find some means by which this power of the developer could be made useful, and the first experiments took the form of adding quantities of citric, and later of tartaric acid. The second worked better than the first; but, as a matter of fact, neither gave a true acid developer, since the addition of acid to a solution of sulphite of soda decomposes the latter, and when there is an excess of sulphite, as there usually is, the developer still remains alkaline, and the only thing to do is to cut down the sulphite in the formula. It was, therefore, necessary to find a substance which could render sulphite of soda solution acid without decomposing it, and the substance which was found to do this was liquid bisulphite of soda solution, such as is on the market, of a density of about 35 degrees Baumé, a solution which has already been much used in photography for preparing the so-called acid fixing-baths.

### A Universal Developer.

In a developer prepared with this substance the bromide has only a relative action when added to a solution of diamidophenol containing excess of sulphite. Its action, however, is very powerful in a solution containing but little sulphite. This fact is of service when dealing with fully exposed negatives, in which case the sulphite may be reduced. This forms the basis of two separate formulæ for the acid diamidophenol developer, which

are different in character, and each of special use in certain cases. Diamidophenol, as we shall show, is a developer suitable for the treatment of all kinds of negative exposures, the development of positive prints and enlargements on bromide paper, and for the development of warm tones on chloride lantern slide. In fact, except that it is unsuitable as a physical developer for P.O.P., it may be called a universal solution.

Those taking up the acid diamidophenol developer must be cautioned to give it a fair trial by using no dish for it which has been used for an alkaline developer. Glass dishes, or those of genuine porcelain, may be cleaned with hydrochloric acid, and may then be used with perfect safety, but dishes of paper-maché, ebonite, or imitations of porcelain should not be used, if an alkali has been contained in them, inasmuch as the porous nature makes it impossible to clean them thoroughly and to remove all traces of solution which they had previously absorbed.

The materials for the developer should be of proper free manufacture. Diamidophenol which has become black is no good for its purpose; when it is good—and that of Lumière is always good—it is a silver grey. A packet of 100 gms. keeps in good condition for six or eight months while being taken from at intervals. Anhydrous sulphite of soda calls for no special remark; it keeps, as does also ammonium bromide, up to the last crystals contained in a supply of moderate quantity.

The bisulphite of soda solution should have a density of 35 degrees Baumé. When on tour in hot countries, when it is inconvenient to carry a solution, the bisulphite may be replaced by potassium metabisulphite, a 5 per cent. solution being used, but the ordinary bisulphite solution is what we think to be preferred.

For the measurements of the small quantities of solution a small graduated measure, holding 30 ccs., is useful; in some cases it is necessary to measure out with fair accuracy 2 ccs. of the bisulphite solution.

Coming now to formulæ for the development of negative plates, that which is now given is prepared for the use of anhydrous sulphite of soda in powder.

#### FORMULA IA.

Diamidophenol .....	1 gm.	15 grs.
Sulphite of soda, anhydrous powder .....	2 gms.	30 grs.
10 per cent. ammonium bromide solution .....	5 ccs.	85 minims.
Sodium bisulphite solution, 45 deg. Baumé .....	5 ccs.	85 minims.
Water.....	150-175 ccs.	5 to 6 oz.

this bath is made up as follows: Into a glass flask, holding ccs. ( $8\frac{3}{4}$  ozs.), are put 10 ccs. ( $1\frac{1}{4}$  ozs.) of water, the gramme diamidophenol is dissolved in it, and then the sulphite, or two together. The water is then added. This is better than using the full quantity of water in which to dissolve the diamidophenol and sulphite; a little water shaken round with two substances dissolves them better than the full quantity. 5 ccs. of the bromide solution are then added from the graduated measure. The quantity given is the maximum, it can be reduced down to 1 cc. or left out altogether, according to the character of the work which is being done. In summer, in the case of exposures on the sea, the full 5 ccs. are often necessary, in winter the bromide may be dispensed with, or a half or two used. It is well to remember that the figure of 5 may be generally adopted, but it is not necessarily invariable. Finally, the 5 ccs. of bisulphite are added; this quantity is invariable.

The formula is used exactly as above once the plates are ready for development, that is to say, it is not necessary to vary it during use. The formula, it may be explained, contains almost the same quantity of water and diamidophenol as of Lumière, but in place of the 6 gms. of sulphite of soda the latter only 2 are used, which reduces the energy and strength of the developer. Diamidophenol will develop with a relatively small proportion of sulphite, 2 gms. being ample; in order to avoid greying of the developer a little sulphite must be used, especially if negatives which have received none too long an exposure are being dealt with.

#### Sulphite and Bromide with Diamidophenol.

Another reason for the reduction in the quantity of sulphite is that in the presence of a larger proportion the bromide has its full restraining action, whereas with a smaller quantity of sulphite the bromide has just as active an effect as it has in ordinary alkaline development. Bromide of ammonia is used in the formula in preference to bromide of potassium, the proportion of bromide being greater. For the rest the quantity of bisulphite, 5 ccs., is adhered to. Its action is twofold. It acts as a restrainer—although not to the extent which one might have suggested—namely, that it can completely arrest development. This it cannot do. A developer containing 5 ccs. of bisulphite, with 2 gms. of anhydrous sulphite, the proportions being as above, was found to develop instantaneous exposures very well; moreover, as the bromide is an instant restrainer, there is no need to use the bisulphite for that purpose. The second part which it plays should not be forgotten; it hardens and strengthens the film of gelatine and prevents frilling, and, moreover, keeps the developer to the proper portions of the film, so that the halation effects which are common with alkaline development are much less pronounced when using the acid formula. Lastly, it acts as a restrainer of the diamidophenol.

Using the acid diamidophenol developer considerably less exposure may be given.\* The key to the successful use of the formula Ia is that too much exposure must not be given. Owing to the relative slowness with which the image appears, even in the high-lights, there is no necessity, as in alkaline development, to remove the plate from the developer as soon as the high-lights are visible at the back of the plate, although the rest of the negative may not be fully completed. It is from this method of procedure that ordinary negatives without detail in the shadows are obtained, but using acid diamidophenol the high-lights possess great transparency, and are never "hard." A good point about the developer is that the high-lights on all the non-exposed parts of the bromide of silver film, once immersed in the solution, have their sensitiveness greatly

reduced. As a result the negative may be left in the solution for much longer than would be necessary for its proper development, a course which could scarcely be followed in the case of alkaline developers. It often happens that a negative is left for ten, twenty, or thirty minutes, owing to the worker being called away, but the plate does not suffer thereby. This applies to formula Ia, whilst in the case of formula II, the negative may be left for several hours. The advantages of this property to busy persons should be obvious. The developer gives rise to no markings, and there is no need to keep it moving during use.

#### FORMULA IB.

Diamidophenol .....	1 gm.	15 grs.
Sodium sulphite, anhydrous, powder ...	3 gms.	45 grs.
10 per cent. ammonium bromide solution	1-2 ccs.	15 to 30 mns
Sodium bisulphite solution .....	5 "	85 minims.
Water .....	150-175 "	5 to 6 oz.

As already stated, the proportions of diamidophenol, water, and bisulphite should not be varied, but modifications may be made in the ammonium bromide and the anhydrous sulphite. In the above formula, which is an excellent one for all instantaneous work where one wishes to obtain a little more vigour, the sulphite may be used as above—namely, reduced by one gramme. In winter, for studio portraits, the bromide can be dispensed with, or only 1 cc. used, whilst keeping the sulphite at 2 to 3 gms. As in formula Ia the anhydrous powder sulphite is used. MM. Lumière have shown that by gradually increasing the proportion of sulphite the reducing power also increases up to a strength of 10 per cent. sulphite; beyond this point the further increase is still greater, and fog is obtained. This fact is used in the II. formula given later.

#### FORMULA IC.

Diamidophenol .....	$\frac{1}{2}$ gm.	8 grs.
10 per cent. potass. bromide.....	5 ccs.	85 minims.
Sodium sulphite, anhydrous, powder ...	1 gm.	15 grs.
Water .....	150 ccs.	5 oz.

To this formula  $\frac{1}{2}$  gm. (8 grs.) of anhydrous sulphite may be added during development, making in all  $1\frac{1}{2}$  gms., but this quantity could be exceeded providing rather slower development is not objected to, although in the ordinary way the time of development is twenty minutes. The last note to be made on formula Ia and its modifications is that an increase in the quantity of anhydrous sulphite increases the strength and vigour of the negative.

For those who can be certain of giving the correct exposure, a formula in which time and instantaneous exposures may be developed together, and from which the negatives will be indistinguishable one from the other, is as follows:—

#### FORMULA ID.

Diamidophenol.....	1 gm.	15 grs.
10 per cent. solution potass. bromide .....	5 ccs.	85 minims.
Sodium bisulphite solution .....	5 "	85 minims.
Sodium sulphite, anhydrous, powder ..	3 gms.	45 grs.
Water .....	175 ccs.	6 oz.

This is a very energetic bath, the negatives appear quickly and should be therefore carefully watched. For the least practised photographers formula Ia is preferable. All the above baths keep for a considerable time, but finally become red, in which state they are of no further use. The baths should be kept in closed bottles, or even in a graduate covered with a glass plate, in this way the solution has been found to keep in good condition for a whole week. 150 to 175 ccs. of bath will develop at least 15 to 18 9 x 12 cm. plates (quarter-plates).

G. BALAGNY.

(To be continued.)

\* Balagny states that the exposure can be reduced to nine-tenths of that given in the case of other developers, such as pyro, hydroquinone, etc.

## INSTANTANEOUS TELEPHOTOGRAPHY.

[The combination of positive and negative, which is most advisable for telephoto work with a hand-camera, occupies Captain Owen Wheeler in the following short article from the excellent "Telephoto Quarterly." Captain Wheeler, who edits and publishes his own useful journal from Strathmore, Princes Road, Weybridge, for the modest sum of 1s. 6d. per annum, post also gives his own experience in the choice of a camera for such work. Our readers must refer to "T.Q." for the reproductions illustrating the facilities of the lens-combinations here advised.—Ens. "B.J."]

BEFORE attempting instantaneous telephotography at any but the lowest magnifications it is necessary to have a clear idea of the relation between magnification and working aperture. Most telephotography of this description comes within what may be termed the normal conditions of exposure, and consequently the rule of multiplying the exposure that would be required if the positive lens only were used by the square of the magnifications holds good. But as it is frequently desirable to give a good deal less than the correct exposure the instantaneous telephotographer may be recommended not to trouble himself much about the square of the magnifications rule, but to pay attention chiefly to the aperture at which he is working. That aperture is the aperture of the positive lens multiplied by the magnifications. If a lens working at  $f/6$  is combined with a tele-negative of any suitable focus, and the separation and camera extension are arranged to give 4 magnifications, the working aperture is  $f/24$ ; if the positive is stopped to  $f/11$  the aperture of the telephoto system becomes  $f/44$ , and so on.

To anyone making this simple calculation the limitations of instantaneous telephotography are quickly obvious. You can get instantaneous photographs at  $f/44$ , but the conditions have to be very favourable indeed, and brilliant results are hardly to be expected. For all practical purposes—although I have myself sometimes gone farther with fair success—I think the limit may be placed at  $f/32$ , while for such weather as is usually available in any but a first-class English summer the effective range of possibilities in shutter work is bounded by  $f/22$ .

There are a few specially constructed tele-objectives which come well within these limits and which for a certain class of camera work may be strongly recommended. Of these the most notable is the new Zeiss tele-lens, which has an equivalent focal length of about 18in., requires a camera extension of only about 6in., and works at  $f/10$ . There are also the Dallmeyer combinations in which a portrait lens working at  $f/3.5$  is used as the positive. In both these cases the positive lens cannot be used separately for ordinary work, and the field covered sharply at full aperture is small. In the Zeiss lens only one focal length is available, and in the Dallmeyer the combination is rather cumbersome and costly. For special purposes both have their uses, but the average worker will probably prefer to know the possibilities of the most useful combinations in which the positive is a high-class anastigmat that can be used separately for the purposes of everyday photography.

### What is the Largest Useful Aperture for the Positive Lens?

Bearing in mind what was said above as to  $f/22$  or thereabouts being the everyday limit of working aperture for quick work, it is clear that a positive with an aperture of less than  $f/7$  is not of much use in instantaneous telephotography, the amount of possible magnification being so restricted. Even when the positive works at  $f/5.6$  the aperture of the telephoto system becomes  $f/22.4$  at four magnifications. One's thoughts, then, fly naturally to the various  $f/4.5$  lenses on the market, possibly even to the notable  $f/3.5$  Tessar. But there is disappointment in store for those who carry these fancies into practice. I have had through my hands some of the very finest  $f/4.5$  lenses made, and have found them most unsatisfactory for telephoto work. Perhaps the reason is that their corrections

are so elaborately good that they are peculiarly sensitive to disturbance by the addition of the tele-negative. Anyhow, I have yet to find the  $f/4.5$  lens that will work well as the positive of a telephoto system without stopping down, and I counsel readers to satisfy themselves by practical experiment on point before procuring such lenses for telephotographic poses.

On the other hand there are  $f/5.6$  lenses which work fairly well as tele-positives at full aperture. They will not cover the plate which in ordinary photography they fill with sharp definition, but a 7in. lens in combination with a negative will give a good 5in. by 4in. picture at 4 magnifications, and that is as much as, perhaps, we ought to expect. Taken all round, I have no hesitation in saying that, at the present stage, the best combination for instantaneous telephotography is one in which the positive works at  $f/5.6$ . This gives nearly 3 magnifications with a working aperture of  $f/16$ , nearly 4 with a working aperture of  $f/22$ , and nearly 5 with a working aperture of  $f/32$ .

### The Best All-round Combination?

When the aperture of the positive lens is settled it is necessary to determine its focal length and that of the tele-negative to be combined with it. This is not such an easy matter as it looks. The circles of illumination produced by telephoto combinations are relatively small, and they vary in the case of different positives. It may save beginners trouble if I say that in my own work I use a 7in. positive combined with a negative, and this at 3 magnifications has a circle of illumination of about 6½in. In practice it may be reckoned on to cover pretty sharply a quarter-plate at 3, and a 5in. by 4in. at 4 magnifications, the apertures being approximately  $f/16$  at  $f/22$ , and the equivalent focal lengths 22 and 28 inches respectively. This I regard as the best all-round telephoto combination for instantaneous work at present available, provided, of course, the right lenses are selected.

### Cameras—Reflex and Twin-lens.

We now come to the question of cameras. The ideal camera for any sort of instantaneous work is, I suppose, a twin-lens reflex, and such a camera would be a valuable acquisition in the serious telephotographer. But to pair telephoto lenses with a camera is an extremely difficult and delicate matter, and though I am told that it can be done, the best opticians consider that result when attained would not be worth the time and trouble which would be involved. The alternative, of course, is to use one of the many single-lens reflexes on the market, bearing in mind that it is one thing to handle those beautiful instruments when fitted with ordinary lenses, and quite another thing to manage them successfully when not only is the vibration caused by the bedding of the mirror—infinite as that is in the case of good patterns—multiplied considerably, but also the balance awkwardly modified by the tele-mount and hood.

I cannot, of course, undertake to discriminate among the numerous types of reflex cameras on the market. As a matter of fact I know of at least half-a-dozen which are all excellently adapted to instantaneous telephoto work, and possessors of "N. and G.," a "Videx," a "Birdland," or any other well-known variety, will certainly not be advised by me to make any change. But there is no harm in my saying that the pattern I use myself

the well-known "Kershaw" type which is embodied in the "Reflex" of Messrs. Marion and Co., and has been adopted by the London and Westminster. The two most important features of this camera are, first, the reflex, which is a very rigid front which is such a satisfactory feature of the "Kershaw" reflexes.

It is a good plan with a reflex to work at, say, three and four magnifications only, and to have the necessary extensions marked on the camera, and the necessary separation indicated on the mount. As pointed out above, if one is working with an  $f/22.4$  at 4 magnifications. If the tele-negative is of 3in.

focus the camera extension in the first instance would be 6in., in the second 12in. Of course, if one desires to work primarily at  $f/16$  and  $f/11$  this can be arranged for by sending a camera and lens mount to a competent firm to be carefully marked. The magnifications would then be very slightly less than 3 and 4 respectively.

Excellent work can be done with cameras other than reflexes when it is possible to focus beforehand, and a focal-plane shutter is by no means a necessity. But for instantaneous telephotography there is nothing like a good reflex, although it may take some little practice before it can be satisfactorily used in the hands. Pending proficiency and where circumstances allow, it can advantageously be worked on a low tripod.

OWEN WHEELER, Captain Reserve of Officers.

## COMMERCIAL RECORD PHOTOGRAPHY.

All that pertains to the documental record of ancient buildings, crosses, tombs, and other memorials of the past it is mon to think only of the efforts put forth by amateur photographers acting alone or as members of one or other of

commercial aggression or defence it is being regularly and largely used, perhaps more so in these two directions than for the information of the next generation, which is the altruistic aim of the record associations. As a record of the positions of

Part of the photographic survey of St. John's College, Oxford, carried out by Mr. A. E. Walsham. The above shows the general view of a side of a quadrangle. The detail view of Section No. 311 is shown in the second figure.

record associations called into existence by the parent presided over by Sir Benjamin Stone. Yet photographic has a considerable commercial side to it. For purposes of

buildings the over-shadowing of a frontage by another block, the occurrence of nuisance by smoke or steam, the camera has become a recognised instrument of modern commercial life,

and has brought money into the pockets of those who have found in such work as this a way out of "darkest portraiture."

Such work calls for skill and resource out of the ordinary, but the monetary return compares very favourably with that from a great deal of the low price portraiture which is done at the present time; it would be a pity if it did not. As a specific example of the record photography which reflects credit upon those responsible for it, we may cite a case which has recently come under our notice, particularly as the work has been carried out in a way which is, we believe new. Mr. A. E. Walsham, architectural photographer, of 45, Chancery Lane, W.C., and 60, Doughty Street, has recently carried out a detailed survey of St. John's College, Oxford, at the request of the trustees, who desired to preserve a record of the carvings of the facades of the courtyards, as well as of many other architectural features which at some future date may need restoration. This work was planned out by Mr. Walsham according to a scheme illus-

Detail view of Section No. 311 of quadrangle of St. John's College, Oxford. Photograph by A. E. Walsham.

trated by the accompanying reproduced photograph of one side of a courtyard. Every piece of detail thus marked and numbered was separately photographed on a large scale from a position level with the subject. The general view thus serves as an index to the detail photographs, which are given the sectional numbers as shown in the example. It says something for the discretion brought to bear on this work that the negative of the detail portions were made by Mr. Walsham at the rate of some forty or fifty per day. The total results, running to some hundreds of prints, each from a different negative, have been inspected by us with much interest as the product of a well ordered scheme and quite apart from their great technical excellence as fine carbon prints. It may be added for the benefit of those whose interest in photography is purely a commercial one, that Mr. Walsham does not grumble at record photography as a business proposition. If he does not photograph an Oxford

college every month, he has discovered the business to be in the photography of articles of manufacture for catalogue other purposes, and has recently arranged a ground floor studio in the centre of London solely for this work.

#### A NEW COUNTRY STUDIO.

WE have recently been interested in seeing evidence of the interest taken in the more suitable furnishing and decoration of studio. The recent series of articles by Mr. Butt on this subject have, we know, created the desire among many of our profes-

readers to take a step forward in the arrangement of their studios, and the desire in many cases has passed into an accomplished fact. The building of a new studio affords a special opportunity for the exercise of the photographer's own taste in such matters. It was therefore with some interest that we inspected the newly opened establishment of Mr. Keith Dannatt in High Street, Haslemere, Surrey. Haslemere on a perfect midsummer day is as attractive a little town as one could find anywhere in England. But it is its vicinity a population of wealthy and cultured people, mar-

whom have been drawn to the neighbourhood by its literary associations—it was the home of Tennyson—as well as by its high position. Moreover, its train communication with London is sufficiently bad to prevent it becoming the resort of the cheaper City man, all of which is in the favour of the photographer. Mr. Keith Dannatt, whose aim is at portraiture such as will appeal to people of artistic taste. The premises are not large, but the

throughout with a nice regard for an harmonious colour scheme. As shown in the second of the two photographs frequent use of a background of oak panelling, the walls of the studio covered elsewhere with a coarse Arras cloth, on which, at the first visit, was arranged some fifty of Mr. Dannatt's photographs of landscape as well as portrait. Although no disguise of the pose of the studio has been attempted, the furnishing has been tried out so as to create an impression of brightness and comfort to the visitor, and this at no great expenditure of money. Mr. Dannatt's work has been seen at recent exhibitions—he is also a member of the Postal Camera Club—and his entrance into professional photography already shows that he is a student of grace and pose, and successful in getting naturalness in the expressions of his sitters. He did well among people who appreciate a personal interest in the photographs made of them.

## Photo-Mechanical Notes.

### The Copper for Half-tone Blocks.

Patent has been granted to a German engineer, named Hugo H. Horgan, of 90, Berliner Strasse, Rixdorf, Berlin, for the use of a copper film soldered to a support of zinc as the material for engraved metal plates. It is stated in the specification (No. 108) that the copper etching plates manufactured in accordance with this method have the advantage, as compared with plates wholly of copper, that the thin rolled copper sheeting used is considerably denser structure, and it is furthermore cleaner, so that etchings will come out better and sharper.

### Half-Tone Becoming Unpopular?

H. Horgan, in the current "Inland Printer," raises a question which may be well considered by English photo-engravers. He says that one of the surest tests of the favour with which artists regard illustration are held is to be found in the popularity of monthly magazines, whose publishers are constantly on the lookout for the kind of illustration that will best suit the public at the same time be inexpensive and practicable. What is meant by this refers to the whole expense attached to an illustration, from the ordering of it to the binding in the magazine. For instance, a publisher finds he can purchase a photograph of a building for as little as 5s. to portray for \$5, while a pen-and-ink drawing of the same building would cost \$50. Now the leaf of book paper on which the engraving of the pen-and-ink drawing is printed might cost 1s. for the edition of the magazine but \$50, while the leaf of coated paper on which the half-tone would be printed, in the same edition, would cost \$150, making a difference of over \$50 in favour of the pen-and-ink drawing, without counting the saving in the line-cut cost compared with the half-tone, or the little trouble in making the line cut is to the half-tone. Now the question comes whether the publisher, which style of illustration pleases the reader? If the publisher gives the greater satisfaction, is it worth the difference? That the publisher is deciding more and more in favour of the line cut can be determined by comparing the number of line cuts in the monthly magazines. In one of the May issues there were fourteen line cuts to four half-tones. It cannot be said that photo-engravers are responsible for the loss in favour of the line cut, for their product has greatly improved. The trouble has not entirely to the printing, and for this the publisher is responsible. The high price of paper has resulted in the use of a line cut, on which the pressman cannot get the results he desires, so he has ceased to take pains, and the consequence is that the line cut does not please the public, while the line cut that is almost any kind of paper with good results, and with the aid of the pressman, is meeting with favour. Engravers must catch this change and take more pains with the engraving work, but, above all things, get better prices for that class of work on account of the increased care which will be required in it."

A PHOTOGRAPHER, who left a letter stating that his name was Hart, was found dead, on July 10, in a bedroom he had hired for a few nights in Cheltenham Place, Brighton. It is believed he had taken poison. The man came from London.

## Exhibitions.

### THE ALLIED ARTISTS' ASSOCIATION, LTD.

There is quite a commercial ring about the style of this latest combination of artists, which appears to be a sort of limited liability company and trade union in one. It holds its first London Salon in the Albert Hall, where there may be seen between three and four thousand works of art, as well as a special section devoted to Russian arts and crafts, under the direction of Princess Marie Tenicoff. The gallery of the hall constitutes the main picture gallery, but the crush rooms and the fronts of the grand tier of boxes are likewise lined with oil pictures. As may be supposed, the great mass of works makes a visit rather a fatiguing undertaking, and the most pleasant part is the proportionally small amount of sculpture, ranged in the arena. Most of this is of a high order of merit. As to the oil and water colours, they include both bad and good, for it is a primary principle of the association that each member has a right to exhibit five works without a veto from a selecting committee. Such a thing does not exist in the A.A.A. In a few cases, but only a few, one feels that a selecting committee would have found useful occupation. When it is considered that all these works are sent largely by artists unknown to the public, it must be admitted that there are an astonishing number of clever painters in these islands. The well-known names figure largely too, however, and many artists of note have joined the association who do not show works this year.

In regard to the hanging and arrangement of the exhibition, it is impossible to say much in the way of praise. The hanging committee, elected by vote from themselves, have had to do their stupendous task in a few days, and in such extenuating circumstances we must find indulgence for the crowding, the rough and ready methods of display, and other unfortunate drawbacks.

Time alone will show whether a non-selective exhibition will bring to the front any hidden geniuses, and whether the A.A.A. will find it possible to live up to its highly creditable manifesto. Such an exhibition as this appears to us to bury, as effectually as ever, whatever worthy works the inducements of the association may invoke.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been received between June 29 to July 4:—

LENSES.—No. 13,902. Improvements in and relating to photographic three-lens objectives. C. P. Goerz A.-G. and Walther Zschokke, 31, Bedford Street, Strand, London.

PLATES.—No. 13,999. Improvements in packages for photographic plates or films and in means for the successive exposure of said plates or films. Optische Anstalt C. P. Goerz A.-G., 31, Bedford Street, Strand, London.

DEVELOPING TANKS.—No. 14,024. Improvements in tanks for developing or treating photographic plates or films. John Owden O'Brien, 6, Bank Street, Manchester.

FLASHLIGHT.—No. 14,030. Improvements in and appertaining to repeating flashlight apparatus, partly applicable to gun-form cameras. Emma Ella Crankshaw, 9, Temple Hey, Liverpool.

DARK SLIDES.—No. 14,127. Photographic dark slide and changing bag combined. Thomas Fenwick Pearson, 94, Church Road, Islington, London.

CINEMATOGRAPH.—No. 14,257. Improvements in disc cinematograph. Ferdinand von Madaler and Alfred Edwin Wallis, 18, Southampton Buildings, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

PIGMENT PRINTING.—No. 20,740. 1907. According to the present invention, instead of the chromium compounds in a photographic solution for pigment printing, ferric salts, cerium salts, and uranium salts are employed, and they are not mixed with the common

albumens, but with alkaline albuminates or acid albumens. These albuminates and albumens are insoluble in pure water, but are soluble without any alteration by means of neutral salts, alkalis, or acids, and which can again be precipitated from these solutions.

When these derivatives of albumens are exposed to the light after they have been mixed with a ferric salt, which, when exposed to the light, decomposes in developing an insoluble oxide, they become less easily soluble in their ordinary solvents. In this manner emulsions can be produced by means of ferric salts, cerium salts, and uranium salts, the sensitiveness of which is nearly equal to the sensitiveness of chromic salt emulsions.

To produce the colloidal substance, the albuminates are dissolved in water, to which previously a solvent (ammonia, borax, carbonate of soda, etc.) has been added; hereupon the ferric salt is added, and, further, the pigment and emulsion is spread on a glass slab or paper. The sensitiveness of the sensitive paper which has thus been produced can be further increased through the addition of colouring substances, such as, for example, metallic violet, etc.

In this manner the papers are sensitised for the yellow and red rays. After the paper has been exposed, the photograph is developed in a bath, which is adapted to dissolve the albuminous substance (ammonia, carbonate of soda, oxalate of potassium).

These papers offer, compared with the chrome papers, the advantage that, although being much more sensitive than the latter, they keep for a much longer time after being sensitised. Jacques Theodore Gateau, Aix-en-Provence, France.

**FOCUSsing MECHANISM.**—No. 18,430. 1907. This invention relates to a method of so adjusting the relative parts of enlarging cameras as to ensure the image being in correct focus at given degrees of magnification, or for stopping the front of ordinary folding cameras when withdrawn, at such positions as will ensure the correct focus of objects at various distances from the camera, according to a pre-arranged scale. A rod is provided, preferably of octagonal section, pivoted at its ends, one of which is provided with a milled head for bringing the various flats of the rod into the operative position. This rod is fixed on to the baseboard of the camera by means of brackets, in such a position that the lens and negative holder run parallel with it. The holders are provided with suitable spring plates which press into cross cuts on the uppermost flat of the rod. Preferably, seven of the flat surfaces only are cut, one

being left plain to allow of the free run of the parts when desirable. The invention may be applied as well to controlling the position of the lens and sensitive paper holder.

In adapting the system to the folding camera the rod is fixed to the baseboard, and the spring plate for engaging in the cuts of the rod would be attached to the lower surface of the front carriage, so that when the front is withdrawn the spring would engage in the particular cut which is uppermost, this having been chosen and adjusted on opening the camera. The cuts are set out according to the focus of the objects at various distances. A rod with any convenient number of flat surfaces might be used if desired. Herbert Holmes and Albert Edwards, Walthamstow; and Houghtons Ltd., High Holborn, London, W.C.

**ROLLER BLIND SHUTTERS.**—No. 18,430. 1907. The invention relates to cameras in which the shutter takes the form of a roller blind,

with a series of apertures of different widths, the time of exposure being determined by the size of the particular aperture and the speed at which the blind is moved. To simplify the operation of such cameras, a direct-reading mechanical indicator, which is operated by the shutter setting mechanism, is provided, and at a glance the exposure speed which will result from any combination of shutter opening and spring tension. Also the shutter has a simplified winding up, and is combined with a releasing mechanism, which controls the movements of the pointer or index finger of the improved exposure-time indicator.

The blind has any required number of graduated openings, provision is made for adjusting the roller spring to any number of different tensions, according to the number of exposure conditions which the shutter is to afford.

To enable the operator to obtain at a glance what exposure will result from the use of a given aperture with a tension of roller spring, there is arranged adjacent to each aperture marks on the central scale, a table (g g' g''), to which pointer is directed when registering with the said aperture and the corresponding shutter-aperture is set for use. Lancaster, Camera House, Broad Street, Birmingham.

**PRINTING FRAMES.**—No. 18,600. 1907. The invention consists in the construction of the backboard of the ordinary existing frames with special hinges, so that it may be opened without its removal. It also carries projecting pins, which fit into vertical slots in the frame, and which prevent any sliding movement. Rollers are mounted eccentrically in the under half of the frame immediately behind the backboard, by means of gudgeons at their ends, the gudgeons being so constructed eccentrically that their axes correspond with the axes of the rollers. The rollers thus revolve with a cam-like motion, and being mounted parallel to the plane of the frame and backboard, exert a pressure which is distributed and can be easily regulated. The terminal rollers are enlarged to form knobs, by which they are released. Richard James Baker, 156, Llandaff Road, Cardiff; and William Jones, 145, Windsor Road, Penarth.

**REVERSING BACKS.**—No. 19,108. 1907. In this invention a wire rod is provided, which lies in a lateral channel along the side of the camera body, the end of the rod being turned down at an angle along the adjoining side of the camera, so as to form a handle. The usual flat metal springs which project over the top edge of the reversing back and engage studs on the backboard, holding it in position, are attached to this rod, instead of being fixed in the camera body. On the rod, and immediately adjacent to the spring, is fixed a circular collar or boss, provided with a flange on its upper side. The springs in their normal positions press against these flat faces, but when the rod is turned the springs are released and the reversing back is released. The spring plates are provided with slopes on the parts opposite the studs on the re-

k, the latter is replaced by simply pressing it towards the era body in the usual manner. Herbert Holmes and William ert Edwards, Walthamstow; and Houghtons Ltd., High born, W.C.

ATOPHGRAPH.—No. 19,713. 1907. The claim is for an indicating aratus for synchronously running cinematographs and talking hines, and its features are as follows:—(1) Two pointers, the tive speeds of which indicate the speeds of the machines, and tric lamps, which also serve the same purpose. (2) Mechanism lighting one lamp if the machines are running synchronously, or or the other lamp, according as one machine is running faster n the other. (3) Contacts carried on the shafts of the pointers controlling the connections of the lamps. (4) Mechanism for trolling the electric lamps. (5) Electrical means for controlling pointers. (6) The combination of the means for operating the ters with the means for controlling the lamps. Jules Green- m, Friedrichstrasse 226, Berlin.

## New Trade Names.

ONT.—No. 300,063. Cinematograph projecting machines and atograph films for use therewith, photographic cameras. The mont Company, Chrono House, 5 and 6, Sherwood Street, adilly Circus, London, W., cinematograph and photographic, trical and mechanical specialists. January 31, 1908.

N (cock in the act of crowing, surrounded by oval, bearing the ds, "cinématographes and films, Pathé Frères, Paris").— 301,610. Cinematographic apparatus and accessories belonging lass 8 relating thereto, including films bearing taken photohs for use with cinematographic apparatus. Compagnie érale de Photographes, Cinématographes, and Appareils de écision, 98, Rue de Richelieu, Paris, France, manufacturers, ch 23, 1908.

## CATALOGUES AND TRADE NOTICES.

OND-HAND APPARATUS.—Those desirous of obtaining high-class atus for a moderate sum should obtain the list of shop-soiled econd-hand goods which Messrs. Newman and Guardia, Ltd., 2, Shaftesbury Avenue, London, W., are offering at consider- educed prices. The items include a number of the well-known nd G." cameras, together with other cameras and lenses of lass manufacture, many useful accessories, and a large selec- f leather cases of all sizes, which are offered at prices much e original cost. As many of these bargains are already ntending purchasers would do well to lose no time in either g for a list or paying a visit to Messrs. Newman and Guardia above address, where the goods may be viewed.

AK DEALERS' LIST.—The Kodak Company send us a list, pre- solely for issue to dealers in the British Isles. It is a volume pages, and fully lists and illustrates a very great variety of utus and materials. In fact, there is scarcely a leading maker eras or sensitive materials who is not represented in its pages. raphic code is conveniently embodied in the list, which can e used by the dealer for obtaining goods easily at short notice. e special accessories will be found described in its pages, and t is certainly a most comprehensive one. It is obtainable free- alers on application to Clerkenwell Road, London, E.C.

Middlesex Photographic Society. "The History and Development of age." T. W. Reader, F.G.S.

## Commercial & Legal Intelligence.

LEGAL NOTICES.—A receiving order in bankruptcy has been made against Edwin Abbott, artist and photographer, of 47, Woodhouse Lane, Leeds.

FRAUDULENT "PHOTOGRAPHER."—In Edinburgh Sheriff Summary Court last week a middle-aged man, named George Wood, admitted having pretended to a number of persons in Musselburgh and other places in Mid-Lothian that he took photographs on postcards and charged twopence each for them, and that if they desired he would take their photographs and send them copies of postcards in the course of ten days or a fortnight on receiving payment of twopence for each copy desired, and thus induced these persons to give him an order for their photographs, and to pay him sums of money, which aggregated 18s. 6d., consisting mostly of amounts from 1s. to 2s. 6d., which he appropriated without supplying or intending to supply the photographs. Accused had two previous convictions for fraud. Sheriff Orphoot remarked that the public must be protected from such systematic and ingenious imposition, and passed sentence of twenty-one days' imprisonment.

A CAPTAIN'S BANKRUPTCY.—A sitting of the Court of Bankruptcy was held last week for the public examination of Graham Archibald Hope, described as formerly of an address in Palace Street, Bucking- ham Gate, a captain in his Majesty's Army. It appeared that the debtor joined the Army in 1893, and retired in September, 1904, with the rank of captain. Since the middle of 1905 he had been occupied in journalistic work, and for a few months last year was also engaged as an actor. From November, 1905, until March of last year he was a partner in a photographic business carried on in New Bond Street, but took no active part in it. The debtor for a few months had also assisted in the business of a company formed to exploit a patented invention relating to a clip for ladies' dresses. He attributed his failure to the trading of that company and of the photographic business having been unsuccessful. The statement of affairs showed total liabilities £693, and no available assets. The examination was closed.

## News and Notes.

THE YORKSHIRE PHOTOGRAPHIC UNION.—The Handbook of the Union for 1908-9 is, as heretofore, designed to be of practical utility to the secretaries of all its affiliated societies, inasmuch as a selection from the list of lectures therein placed at their disposal will doubtless provide them with much interesting material for their winter programme. Also the names of lecturers and their intimate acquaintance with the subject matter of their lectures should prove an easy means of filling the societies' meeting rooms. Should there still be any Yorkshire societies who have not availed themselves of the privileges afforded by affiliation they would do well, we think, to write for particulars to the secretary of the Union, Mr. Ezra Clough, 10, Farcliffe Road, Bradford.

MR. DAVID BLOUNT, of James Bacon and Sons, photographers, Newcastle, was summoned to Leeds in connection with the Royal visit, and at Harewood House had the honour of photographing His Majesty King Edward.

PHOTOGRAPHS WANTED OF BLACKPOOL.—The Blackpool Town Council have decided to organise a competition for photographs for use in the next issue of the official guide. Councillors having inquired about "the travelling camera men who swarmed the town in the season," it was stated that prizes would not be given to this class, but an amendment that the competition be restricted to persons who paid rates in Blackpool was defeated.

"URBANORA" TO THE PALACE THEATRE.—After a continuous, as well as a phenomenally successful, run of 420 consecutive weeks (or rather more than eight years) at the Alhambra Theatre—which surely constitutes a record in stage booking—the unrivalled exhibi- tion of "Urbanora" Animated Pictures will be, on and from Bank

Holiday, Monday, August 3 next, transferred to, and exclusively shown at London's leading variety theatre, the Palace. That the cinematograph now forms the staple item in the ideal vaudeville programme Mr. Alfred Butt has long recognised, and that Mr. Charles Urban possesses a supreme knowledge of cinematography and all that appertains to it has been universally attested by the Press. Henceforth, therefore, the "Urbanora" Animated Pictures, with their practically illimitable range of subjects, will be kept upon the highest rung of the bioscopic ladder, and, being frequently varied and ever topical, will form yet another distinctive feature in the Palace's always diversified and refined programme.

WHITAKER "PHOTO-STAINS."—A correspondent writes:—"I notice in your current correspondence column that a Mr. Spence asks about 'Whitaker' photo-stains, and that you have been unable to trace them. I have used them for some time. I purchase them locally from 'Butcher and Curnow,' Blackheath. The bottles are labelled, 'Whitaker, Chemical Works, Kendal.'"

THE "MONTHLY PHOTO JOURNAL" is a new publication from Japan, devoted, as its name indicates, to photographic art. It is published by R. Konishi, Nichome, Honcho, Tokyo, Japan, entirely in Japanese, and contains some interesting illustrations in half-tone and colotype.

OPTICAL CONVENTION, 1909.—The permanent committee, appointed at the first Optical Convention in 1905, has now taken the preliminary steps for holding the second Optical Convention in London in May, 1909.

An exhibition of instruments will be arranged, which will be scientific in character, and will consist principally of instruments manufactured in this country; it will be designed to display recent progress, and to stimulate future effort. A unique opportunity will thus be afforded of bringing optical and other scientific instruments to the notice of manufacturers, of scientific men, and of the public. It is further proposed to invite from foreign manufacturing firms special exhibits of instruments which are either not made at all in this country, or only made to a comparatively small extent, so that the visitors to the exhibition may see the best of what is being done in foreign countries. An illustrated catalogue of the exhibition will be prepared, which will fully describe the special character and construction of particular instruments. Not only will this increase the value of the exhibition from the scientific point of view, but it will also serve directly the interests of manufacturers and dealers. It is hoped that such a catalogue may be specially serviceable to manufacturers in making their instruments known in colonial and foreign markets, and it may be remarked that the catalogue of the 1905 Convention was very successful in this direction. A guarantee fund has been started to enable the committee to begin work, and a list of the contributors to, and guarantors of, a general fund will be issued shortly. The hon. treasurer, Mr. James Aitchison, 14, Newgate Street, E.C., will be glad to receive further promises for the guarantee fund or contributions towards the expenses of the Convention.

A preliminary list of officers has been made, consisting of the acting president, Dr. R. T. Glazebrook, F.R.S., director of the National Physical Laboratory; hon. treasurer, Mr. J. Aitchison, 14, Newgate Street, E.C.; hon. secretary, Professor W. Cassie, Brantwood, Englefield Green, Surrey. The Executive Committee consists of: Chairman, Dr. R. Mullineux Walmsley, F.R.S.E., Principal of the Northampton Institute; hon. secretary, the hon. secretary of the Convention. Finance Sub-committee: Chairman, the hon. treasurer of the Convention; hon. secretary, the hon. secretary of the Convention. Papers Sub-committee: Chairman, the acting president of the Convention; hon. secretary, Mr. S. D. Chalmers. Exhibition Sub-committee: Chairman, Mr. W. Salt; hon. secretary, Mr. J. H. Sutcliffe. Catalogue Sub-committee: Chairman: Mr. W. Rosenhain; hon. secretary, Mr. A. N. Disney.

With a view to arousing interest in the Convention throughout the country generally, a provincial sub-committee is being formed, with Professor J. H. Poynting, F.R.S., J.P., of the University of Birmingham, as chairman, and as soon as possible a list will be published of those who have consented to act as local secretaries.

AERIAL COLOUR PHOTOGRAPHS.—Professor Miethe, writes the "Daily Mail," has taken some remarkable colour photographs from

a balloon by the three-colour process, which give a wonderful idea of what a large town looks like as it fades away into the distance while an ascent is being made. Colour photographs, taken in one tenth of a second at a height of 500 yards, show how lifeless the bright colours of nature appear when observed from the sky.

WHITewASHING ROOFS.—The output of a cotton mill is appreciably affected by the comfort of the operatives, and in this tropical weather comparative coolness means much. The "Manchester Guardian" says that several cotton manufacturers and spinners have recognised this, and are keeping their mills cool by the simple and inexpensive plan of whitewashing the roofs. It is surprising that this practice is not more generally adopted, not only for cotton mills, but for buildings of all kinds. No doubt the roofs are unpleasant to the eye when under the hot sun, but one does not see much of them unless it be from a considerable distance, in which case the glare loses much of its painfulness. As a rule, the roofs only require whitewashing once a year, at the beginning of the summer. Perhaps it is too much to expect whitened walls, but in large, smoky towns, with tall buildings and narrow streets, whitewashed walls would add greatly to the brightness, cleanliness, and coolness of many a purlieu.

## Correspondence.

\*• Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\*• We do not undertake responsibility for the opinions expressed by our correspondents.

### SLOW ORTHOCHROMATIC PLATES FOR THE PHOTOGRAPHY OF LIGHTNING FLASHES.

To the Editors.

Gentlemen,—Some two years ago I suggested, through the medium of the "B.J." (July 27, 1906, p. 598), that the Wellington "Ortho-process" plates were excellent for the photography of clouds, whether from a scientific or pictorial point of view. By reason of their being slow they give sufficient contrast when developed with hydroquinone to show the clouds form, and the fact that they are also orthochromatic will serve to give a truer colour rendering, a point that is most essential when clouds are photographed as an aid to scientific research.

Should the photographer, however, require a pictorial cloud effect he might easily obtain the necessary result by using the same plate, but with a pyro-soda developer. I would recommend the following using equal quantities of each of A and B:—

A	Pyrogallie acid .....	½ oz.
	Metabisulphite potash .....	½ oz.
	Water .....	40 oz.
B	Sodium sulphite .....	4 oz.
	Sodium carbonate .....	4 oz.
	Water .....	40 oz.

I now take this opportunity of saying that indeed these plates are excellent for the photography of lightning. In the former article referred to a rapid iso plate as necessary for lightning photography, but experience has made me greatly change this idea. I am enclosing a small selection of photographs of lightning taken on "Ortho Process" plates during the storms of June 4 last and on July 4. I think you will agree that they bear out my statement very well.

I find that in using a fast plate we are apt to get a great deal of fog, through any sheet-lightning that may chance to come during the interval between the forked flashes, whereas in a slow plate this has little or no effect. I was particularly successful during the storms of June 4 last, having exposed some dozen or more plates, and without exception, I obtained pictures of lightning on all of them. I am, dear Sirs, yours faithfully,

J. HOWDEN WILKIE, F.R.P.S.

[The prints sent by our correspondent are evidently from negative very free from fog.—EDS. "B. J."]

# Answers to Correspondents.

*matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C."* Inattention to this ensures delay.

*Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., Wellington Street, Strand, London, W.C.*

*For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 7d. each photograph, to cover cost of registration fee, form, etc. 100 unmounted copies of each photograph must be sent with the application.*

## GRAPHS REGISTERED:—

*Driver, Riddlesdale House, Ardsleigh, near Colchester. Photograph of Ash Farm at Coggeshall, Essex.*

*Keys, Studio, Market Place, Denton, Manchester. Photograph of Denton Hall Club and Committee with Cup.*

*Mr LEVY (Asnières).—You will have seen now the paragraph page 522 of last week's issue.*

*(Blackheath).—Many thanks for your note, which, you see, we are using.*

*W. G. NEY.—It is practically impossible for us to say unless you use the sensitive paper. Surely you can tell whether a paper is P., bromide, or gaslight. It must be one or the other.*

*S.—The modern portrait lens has a small field, over which definition is obtained. A lens of 6 or 7 inches focal length—do not say what focus yours is—will cover a carte de visite, not much more.*

*on P.O.P.—Could you, through your journal, let me know is the cause of the stains on enclosed postcards? A gentleman brought me over a hundred postcards to tone, and I made up a bath for them, of the same as I had used myself before. Over 100 of them have these stains on them. I cannot think it is fault of the bath, as I toned some for myself at the same time, they were all right. Do you think it is anything to do with the cards? They are —'s cards.—STAINS.*

*One of your samples suggests that the mark is due to two cards being together in the toning bath. In the other cases possibly the printer handled the cards too freely, and so produced greasy marks that refused to tone. Beyond this we cannot suggest any remedy for the spots. It is very unlikely that the cards themselves are to blame.*

*ON TONING.—We are anxious to tone our bromide postcard to a certain shade, but after experimenting only arrive at the results of faded samples. We have marked on back of each the formula used. Can you assist us by giving a formula that will produce the desired tone or give us any help in the matter?—W. A. B.*

*I do not know any certain method of producing the tone shown on your specimen by ordinary methods of sulphide toning. Possibly the thiomolybdate toner put on the market by H. Edmund and will fulfil your requirements most nearly. The hypo alum is probably the next best, and if you try this with various strengths of bromide paper you may get very near the right tone. Sample tones you send are by no means as good as they should be. For the Kodak formula you want correctly exposed and quite developed prints, and you should use quite fresh pure sulphide; good tones are hopeless otherwise. With the thiomolybdate a rather weak print is best, as the strong solution is an insufferable. For hypo alum toning you want strong, fully developed prints, and the toning bath must be an old, well-used one to get good tones. It may be improved by the addition of a little silver salt if it is too fresh.*

*S.—1. The lens, as we reported in our issue of June 5, is certainly an excellent one. Most probably it is exactly similar in construction to the former of the two mentioned, the patent in which has expired. Whether it is quite equal in quality depends on*

*workmanship. 2. Both of the two you name are first-rate instruments. 3. There is very little difference. One is practically the same as the other.*

*DEALER.—What your friend says is quite correct. If what you are doing reaches the ears of the Pharmaceutical Society it will be down upon you sharp for its £5 penalty. It is only members of that body who are allowed to sell certain poisons, and bichloride of mercury is one of them. Whether you label the bottle poison or not will make no difference whatever, the Act is still infringed.*

*RAIN OR DISTILLED WATER.—I have often read in text-books of photography, "use rain or distilled water" in making up solutions. My reason for writing to you is that I am about trying my hand with the wet collodion process for lantern slides, and I want to know whether ordinary rain water is as good as distilled water for making the silver bath, as the latter is difficult to get in country places.—GEO. SIMKINS.*

*Rain water is, theoretically, as good as distilled water if it is pure, which is rarely the case when it is caught from the roofs of buildings. Then it is usually contaminated with organic matter. If it is caught in vessels in the quite open country it can generally be relied upon. But if caught in the neighbourhood of large towns—particularly manufacturing places—the probability is that it will be more or less impregnated with impurities of one sort or another. However, we should recommend you to get the cleanest rain water you can, put it in a white glass bottle, and add a few crystals of nitrate of silver to it, and then expose to sunlight for a few days. Then, probably, the water will be discoloured, a precipitate thrown down, and when that is filtered out the water can be as safely used for silver solutions as if it were distilled water.*

*DISTORTION.—Herewith I enclose prints from two negatives of a tall building. My customer complains that the sides of the building do not look right, as they are not parallel, and he will not have the pictures, or pay for them, unless I can produce better ones. The lens is a new one (—'s rapid rectilinear), which I bought, partly, to execute this order with, as he has hitherto been a good customer for portraits. When I bought the lens I was told that it was perfectly rectilinear, and would give absolutely straight lines, but you see by the examples that it does not, as the sides of the building lean inwards towards the top. Shall I not have the right to demand the money I paid for the lens returned? —PROVINCIAL.*

*Your examples show no fault whatever in the lens. The lines are perfectly straight, as all rectilinear lenses yield them. The convergence of the lines in the upper part of the picture is no fault of the lens, but that of its user. The camera was tilted to get the upper part of the building in the picture, and the swing-back, or rising front, was not brought into requisition.*

*LENS FOR GROUP.—I have arranged to take a wedding group next week, the size to be 12 by 10. The only lens I have that will cover that size is a portrait lens 4½ in. in diameter, but it does not cover well to the corners, even when tolerably well stopped down. A friend has offered me the loan of a 12 by 10 R.R., by Dallmeyer. Which of the two would be the best for me to use? Would the R.R. be too slow for the purpose? I am putting this query to you, as I have had but little experience out of the studio.—WALLACE.*

*By all means use the R.R. It will cover the plate better than the portrait combination, and will, out of doors, be quite rapid enough if moderately quick plates be employed.*

*P.O.P. PERMANENCY.—Would coating P.O.P. prints with enamel collodion be of any advantage in regard to adding to their permanency?—J. Rosso.*

*Theoretically it should be, because the collodion protects the prints from the atmosphere, but, in practice, it seems to have little or no effect. The best way of adding to the stability of gelatine prints is to very thoroughly fix them, and then ensure that they are properly washed.*

*HANTS.—Any good lens, whether a rapid rectilinear or a single landscape, of 6 in. focus should cover the quarter-plate right up to the corners. But the latter will require to be stopped down to about f/16 in order to get a sharp and crisp image.*

*R. H. HALE.—As we are continually saying, in answering correspondents, the only way to ascertain if a photograph is copyright is by searching the register at Stationers' Hall. In your case there is the difficulty that you do not know the name of the photographer who*

## SUMMARY.

W. E. Debenham recommends hydrochloric acid as a ready method of reviving tarnished daguerreotypes. (P. 560.)

ent has been taken out in France by the Lumière Bros. for a process of manufacturing a colour screen-plate of geometrical pattern. (P. 57.)

Balagby, in the concluding portion of the article dealing with the use of diamidophenol in acid solution as a developer, gives the method for development of assorted exposures, time and instantaneous for the development of bromide papers and for the production of warm tones on lantern slides. (P. 560.)

complaints are being made in Germany as to the harm done the trade abroad by the Government's insistence on the cards giving the names of those producing them. (P. 558.)

correspondent raises the question of the sending of prints to exhibitions unframed. (P. 574.)

ideas of an American agent for advertising a photographic process. (P. 563.)

first part of an article by Mr. Harold Baker on photogravure the professional photographer deals with the cleaning and graining of the plate. (P. 566.)

description of a method alleged to be suitable for the production of portrait prints in several colours by a toning process is given on p. 567.

the notes by way of caution to those who have offered to them methods relating to photography are the subject of an editorial on p. 558.

W. Dieselhurst contributes a description of measuring the focal-plane shutters. (P. 564.)

exposure indicator, a studio stand, a continuous printing machine, and the telegraphic transmission of pictures are among the news of the week. (P. 569.)

ful advice on a number of practical topics is contained in the article by Mr. A. Lockett, "Some Photographic Fallacies." (P. 565.)

## EX CATHEDRA.

### The Northern Exhibition, 1909.

January 6 to 27 is the period during which the Northern Exhibition is to be seen next year in the City Art Gallery, Manchester. Mr. S. L. Coulthurst, as secretary of the exhibition committee, of which Dr. Lakin is chairman, is evidently laying his plans with the single aim of making the show equal to, if not an advance on, what has been done at Liverpool. A feature is to be made of Autochrome and other methods of colour photography, and it looks as though the Manchester committee was going to be busy through the Christmas holidays. They have certainly done well in appointing but one judge, and have been fortunate in persuading Mr. J. C. S. Mummery to undertake the office. All would seem to presage a great show in Manchester, for particulars whereof the prospectus and entry form, obtainable from Mr. Coulthurst, Broad Oak Road, Worsley, Manchester, should be consulted.

\* \* \*

### A New Lumière Screen-Plate Process.

The firm of A. Lumière et ses Fils has taken out a patent in France for a process of manufacture of a screen-filter plate which is quite different from that employed for the Autochrome plate. The published specification, No. 386,147, explains it to be a method of forming a filter-screen of definite geometrical pattern by imprinting lines upon a sheet of gelatine-coated glass. Two-thirds of the surface is first coated with a series of lines in greasy ink. These lines serve as a temporary resist; the uncovered parts of the plate (one-third of the surface) are treated with a dye solution, which penetrates the gelatine, and, after drying, the whole plate is coated with a varnish which is without action on the greasy ink and is insoluble in solvents of the latter. The ink is then removed with a solvent and a series of varnished coloured lines left on the plate. One half of the total surface is then covered with a series of lines in greasy ink, a second application of dye made, a varnish applied, and the ink resist removed as before, after which the remaining third of the plate is completely filled by a bath of the third dye. The process is done without registration, and would appear to have been worked out by the Lumières as an alternative and cheaper method of preparing a screen-plate. To what point the process has been completed on a manufacturing scale we have no information at all, nor is there any reason whatever to suppose that plates made by the new process are coming on to the market in the near future. We shall refer to this and other new features in screen-plate processes in the "Colour Photography" Supplement of August 7.

### German Picture Postcards.

It is a well-known fact that German picture postcard manufacturers have for a long time been making strenuous efforts to secure the picture postcard market of the world. Their activities extend in all directions, and they have in all important centres and tourist resorts throughout the world energetic representatives, who are so skilled in pushing these wares that the market shows a remarkable and steady yearly increase. In fact, for some unaccountable reason, they seem to have a monopoly of many districts, which the native manufacturers, who might benefit most from the industry, apparently consider it not worth their while to cultivate. Yet, however successful he may be abroad, the German picture postcard manufacturer has his difficulties to overcome at home. Though the authorities recognise the importance of the industry, and point with some pride to the prominent place it occupies in the export list, they do not scruple to come down upon them now and then with a somewhat heavy hand. Of late the police officials have begun to harass the manufacturers, and it is quite the order of the day to learn that they have confiscated large consignments of postcards prepared for export. The reason they give for this is not because the postcards contain anything that might be calculated to corrupt the politics of the country, or that the pictures are immoral, but merely that they do not conform to the law and give on each picture postcard the name and address of the printer and publisher. The manufacturers hold that it is not necessary to observe this law when the postcards are intended for export. Further, they say that to insist on the enforcing of the law would greatly handicap the trade, and possibly end by ruining it, as, according to the manufacturers of picture postcards, there is abroad a pronounced prejudice against buying postcards which are known to be made in Germany. Representations have been made through the Chamber of Commerce to the Home Minister and other responsible authorities with a view to putting an end to this annoying police interference, and several newspapers have taken sides with the manufacturers in bringing pressure to bear in these quarters to let picture postcards pass out of the country without bearing upon them the names and addresses of those responsible for their production.

### Cheap Railway Fares for Photographers.

Recently the idea has been revived that photographers should be able to obtain concessions from the railway companies in the form of cheap tickets similar to those issued to fishermen. This is a very old idea, and up to the present it has not been received with any encouragement by the companies. The reply always is that photographers travelling in parties of twenty or so can already obtain concessions in the way of reduced fares, just like any ordinary excursion party, but the idea that single photographers should have special rates meets with nothing but a decided negative. For our own part we are rather inclined to sympathise with the companies in this matter. Photographers are numerous and rapidly increasing in numbers. Soon, those who do not possess a camera will be in the minority, and then the majority of passengers will be able to claim reduced fares by virtue of carrying their cameras. The precedent of fishermen's tickets is a bad one. It is only a very old privilege that still survives. It is comparatively harmless, seeing that fishermen are so few, but so far as we can see it affords no reason for any claim on the part of photographers to a similar privilege. The agitation for this seems to us to be hopeless and unreasonable. On the other hand, it might be possible to obtain a reduction in the number of persons required to make a privileged "excursion party." Many societies have trouble in securing the twenty usually

necessary, while they can easily find twelve or fifteen. the same time, however, we do not quite see why photographic excursion or "club outing" parties should be specially distinguished from other excursion parties receive special privileges, and we doubt very much if will ever make the companies quite see why they should be so singled out for favour.

\* \* \*

### Large Direct Portraits.

One of the ideas which our American professional friends have worked satisfactorily is the production of a large portrait, in addition to the cabinet negative for the filling of the customer's order. Most usual 10 by 8 plate is exposed, and the carefully retouched finished picture is shown with the other proofs, and in the majority of cases finds its way to the sitter's home. Only half the larger pictures so produced are purchased; the venture is a paying one, and the pictures declined in most instances available as specimens. Of course, a little discrimination is needed as to the kind of sitters whom to expose the large size plate. It has sometimes been suggested that this speculative work is in the nature of the free sitting, but this contention can hardly be good when a sitter has spontaneously come to the studio. It might be thought that one of the smaller negatives could be enlarged to, say, 10 by 8, but if this is done a proof should not be shown, as it may happen that the larger picture is much admired, the customer on seeing the small print exactly the same may decide against spending the extra amount on what is really only a duplicate. Besides, it is very doubtful if a plainotype or camera enlargement can be readily made which will have "quality" as a direct print; and, in fact, the work of making such a fine enlargement would probably involve a greater amount of work than the exposure of the plate for the sitter. If the small negative is retouched the retouched negative is very grainy when enlarged, and if the enlargement is made from the untouched original the amount of retouching required is equal to that needed on a direct negative.

### THE PHOTOGRAPHIC PROCESS-MONGER

The process-monger, if we can judge from letters we recently received, is still with us, and is, in some instances, doing a somewhat profitable trade. Some in this line of business are mere charlatans with plenty of plausible and a considerable amount of assurance, which they play to the best effect on those of limited experience in different photographic processes. It is no unusual thing for us to have letters saying that the writer has paid a sum of two, five, or perhaps more, guineas for a "secret process," which he afterwards finds is not new, and, moreover, has been published in this and other journals. In fact, instead of something new, it is really an old method dish up afresh.

The vending of so-called secret processes, or methods of working, is no new idea. It dates back to the daguer type days, when workers were anxious to gain what information they could to improve their knowledge. In the early days for trifling improvements they often paid good prices, it does not follow that all secret processes that have come into time to be vended are not genuine or novel. I call to mind the method of Sarony of making enlargements and also that of Edwards for the same purpose, which were exploited in the early seventies. The former of these consisted in the making an enlarged transparency direct from the negative, working that up, and from it making another negative either the same size or still further enlarged. At that time this procedure was really a novelty, although at the present time it is a very general system of work.

latter consisted in making a transparency by contact printing, by the albumen process, and, from that, making an enlarged negative. In this case the chief secret was in getting an unfixed transparency, as it was then assumed to be a softer and better result was thus obtained. Both the albumen and the contact processes yielded excellent results, and were really profitable at the time.

Then, again, there was the method of the late Mr. Herbert Faulkner for making backgrounds, which, now known as the powder process, was at first vended as a secret process. There were other methods about that time which were sold as secret or semi-secret, or were the subject of patents and licences, more or less exclusive. I may mention the Van der Weyde method of finishing photographic images by the incorporation with powder colour of a gritty substance (such as pumice powder or the like), which abraded the surface of the picture—a very general method of working nowadays, but a novelty in its time. The anti-Turner process of finishing was somewhat similar, and about the middle seventies the Lambert patented processes were brought forward, and for a time had very good run, substantial fees being paid for licence to work them.

Of the above processes were bona fide, and would do what was claimed for them, but many of those who paid money for the right to work them were disappointed. However, was not because the processes were at fault, but because the buyers had not the skill to produce results equal to the introducers of them, who were all skilled photographers, the last named (Lambert) in particular. The results done by the exploiters just mentioned were really fine, but the mere paying of a sum of money for the privilege of working the methods did not, of course, confer the skill necessary to produce similar pictures. We remember being present at several demonstrations by Lambert in the middle seventies, and the way in which he converted an apparently worthless collodion negative into a really good printing one was surprising. This he did by quite a few touches, on the mineral paper on the back with a stump lightly charged with plumbago, the work taking only three or four minutes. Here the final equation was the chief factor.

A vendor of an alleged secret process naturally does seek his customers invariably in photographic circles, and the obvious reason that the ordinary well-informed photographer is not a likely person to be taken in. But advertisements in the lay press are constantly being used, and for the sale of a formula for making P.O.P. Per-who reply to such an advertisement, which usually offers a high return for the expenditure of little money, are not that the proposition relates to the making of a photographic printing paper by a secret formula owned by the advertiser. The inquirer is further told that the paper is manufactured at home on a small scale, that it can be made readily direct to the consumer, and that this business, even on a moderate scale, will command a large profit for the undertaking it. When the purchaser has paid his £20, or £40 for this valuable formula, and has learnt to make the paper, he then wakes up to find that in thus launching his enterprise he has to compete with all the makers of recognised brands of printing-out paper, and cannot distinguish himself of the usual channels of distribution. Therefore, he is probably not long in discovering that the formula is practically the same as that contained in the modern text-books. This fraud, of the constant repetition of which we have frequent evidence, unfortunately does not bring its exponent within the clutches of the law.

A different form of fraud, which has been much practised in the past, although we have not heard of it of late, is in the advertising, again in the lay press, of home

employment by which ladies can obtain a good livelihood by genteel means. When inquiries are made of the advertiser, it is discovered that the work consists in the colouring of photographs (by the crystoleum process) for photographers, who, it is alleged, will pay high prices for it. The advertiser takes money from his inquirers for instruction in the process and for the sale of materials, and leaves them to discover that, so far as the professional photographer is concerned, the crystoleum process is as dead as Queen Anne. The whole thing is a cruel deception, which is not to say, of course, that the crystoleum process as a recreative exercise for amateur purposes is not a perfectly legitimate subject for advertisement for the sale of materials. The fraud lies in representing it as a remunerative employment.

The process world of late has perhaps afforded more examples of the sale of alleged valuable secret processes than has the domain of photographic technique. It cannot be said that the information sold is valueless, but those who are intimate with process matters will confirm us when we describe recent processes, which have been sold to photo-engravers, as simply the oldest methods resuscitated. These antique methods have been offered by men of a certain magnetic personality and a skill in manipulation which enabled them to obtain comparatively large sums for processes which were perfectly well known twenty years ago and were discarded on account of the difficulty of working them. There is a recent instance in which one process-monger in a single summer obtained £750 as the result of selling a process to eight different firms, every one of which at the present time has abandoned the method as commercially useless.

The above considerations will have shown that in purchasing a secret process the buyer should assure himself first that the process as described by the vendor will do what is claimed for it without the exercise of extraordinary personal skill, and secondly that the description actually contains information which could not be obtained in periodical or other publications. Quite naturally, the vendor of a process will not communicate the details to an intending buyer except under some form of agreement, which usually amounts to a firm promise to purchase, but in cases where the amount to be paid for a process is a considerable sum there is the obvious alternative of confiding the method to a third independent party, who, while possessing sufficient knowledge both of the craft and its literature, to say whether the process is both practical and novel, may at the same time be depended upon to respect the confidence placed in him. Naturally such persons, several of whom might be named in the photographic world, would not undertake duties of this character for the trifling sum for which some processes are hawked about, and therefore their services are likely to be requisitioned only in the event of a sale involving some considerable expenditure.

It would surprise, perhaps, many photographers to learn the incredible credulity of some persons as to the value of a formula or working method. The fact that an alleged inventor can bring forward chemical symbols and photographic prescriptions would appear to endow him in the eyes of the would-be purchaser with the wisdom of Solomon and the knowledge of "all the authorities."

It never seems to occur to these people that writing formulæ is as easy as shelling peas. "I can call spirits from the vasty deep," said Glendower. "But will they come when you do call?" And equally the self-styled photographic inventor can write new chemicals into the formula for an emulsion or sensitiser without particular regard to the fact that they in no way influence the properties of these mixtures. As we have said above, the two essential points to be investigated in such cases are:

first whether the formula is practicable, and, assuming that it is, whether it actually contains any constituent other than those occurring in standard published directions. We have had on several occasions the opportunity of applying this method to claims for secret processes.

The result has usually been that the "inventor" has preferred to withdraw from the negotiations, and we point to more than one instance in which the idea formula sold to another party has proved to be a bogus.

## CLEANING DAGUERREOTYPES.

In an article on Copying in the "Journal" for July 3, reference is made to the iridescent film often found obscuring Daguerreotypes, and to the method of cleaning and restoring them by the use of a solution of cyanide of potassium.

As there are still many Daguerreotypes existing which, although they cannot truly be said to have faded, have become covered by the objectionable iridescence mentioned, it occurs to me that it may be of service to describe a method which I have never seen published, but have used as occasion required from the time when Daguerreotypes were still made commercially, until the present. Although when I saw the cyanide method published, I tried it with success, I did not consider it desirable to abandon in its favour the process which I had hitherto used. As there are various details to be observed in cleaning Daguerreotypes, besides the selection of the agent to be employed, I propose to describe the process in full.

The things necessary to have in readiness are, a pair of pliers, a bottle of pure hydrochloric acid, a tap of gently running water or a jug filled with water, a bottle of clean, distilled water, wherewith to finish the washing, and a spirit lamp or Bunsen flame for drying off.

Daguerreotypes commonly have the edges and corners slightly turned down, in order to avoid injury to the polishing buffs. With the pliers one corner may be very slightly turned up, and this corner should be firmly held by the pliers during the operation of cleaning. Holding the Daguerreotype as horizontally as may be over a sink or basin, enough hydrochloric acid is poured on to cover the plate. The iridescence disappears almost instantly, and the plate is then washed, first with ordinary, and finally with distilled water. In the course of washing the plate

may be taken in the hand while the ends of the plate are rinsed to get rid of any acid held between them and the plate. The plate should be dried in such a way that the moisture appears from one side or corner to the opposite in one without halt or stoppage. To secure this, hold the plate the flame with the corner held by the pliers slightly than the opposite corner. As soon as one corner begins to hold the plate nearly upright, still keeping the pliers side and if the plate is of the right heat the drying will continue without stopping, in an even wave from top to bottom the drying becomes so slow that there seems a danger of (which might give rise to a line), make it hot from the downwards, or assist the drying by blowing, or do both dry all over. The corner first bent up may now be straightened out again, and the Daguerreotype should finally be sealed from the air by fastening gum paper all round the edges protecting glass and mat, and on to the back of the plate.

The object of the distilled water is to prevent the deposit of the plate, of traces of the lime and other salts contained in ordinary water, but the distilled water should be examined being held up to the light, and if there are any floating particles they should be removed by filtration.

The hydrochloric acid should be the pure kind obtained from a chemist, and not the commercial yellow kind, which contains traces of nitric acid.

Daguerreotypes were enhanced in beauty by toning with gold, and though I do not say that for the short time the cyanide was used, is kept on the plate, it will sensibly remove the gold, it seems to me more probable that it should do so does the pure hydrochloric acid.

W. E. DEBEN

## DEVELOPMENT WITH DIAMIDOPHENOL IN ACID SOLUTION.

### II.

[The use of diamidophenol in conjunction with sodium bisulphite has found an enthusiastic champion in M. Balagny, whose published papers on the subject are scattered through the French photographic journals for the past few years. A medal was recently awarded M. Balagny for his method of using diamidophenol for obtaining warm tones on gelatino-chloride plates, but for negatives of both time and instantaneous exposures, bromide papers, as well as lantern slides, the properties of the diamidophenol formula are described by him in terms which are perhaps at times somewhat too glowing, but which, nevertheless, are worthy of attention, particularly by users of Autochrome plates, in view of the experiments by M. Charles Simmen on the use of the same developer for the development of Autochromes in a red light. The following formulae, therefore, which are abridged from M. Balagny's recent "Monographie du Diamidophenol en Liqueur Acide", published by MM. Gauthier Villars, may be here translated as an abstract of the chief technical advice which the author has to give.—Eds. "B.J."]

In the second series of formulæ now to be given the anhydrous sulphite of soda and bisulphite should mix together in a solution of bisulphite prepared beforehand, not, as in I. series, employed separately in compounding the formula. The following solution, therefore, is thus to be made:

#### Solution S.

125 ccs. ( $4\frac{1}{4}$  ozs.) of water are placed in a graduated flask, and 20 gms. (310 grs.) sulphite of soda added and shaken until dissolved. 75 ccs. ( $2\frac{1}{2}$  ozs.) of bisulphite of soda solution are then added, and the whole, after shaking, transferred to a 250 ccs.

bottle ( $8\frac{3}{4}$  ozs.), pouring in any sulphite which is not completely dissolved. The solution will be clear on the following day. This formula, it will be seen, gives one gramme of sulphite of soda to 3.75 ccs. of bisulphite per 10 ccs. of liquid. It is also to be noted that as soon as the mixture of sulphite and bisulphite has been made, all odour of sulphurous acid disappears. A liquid prepared in this way will keep for more than a year, the only defect that can occur being a deposition of a little sulphite on the glass, although this is of rare occurrence, the solution being of 10 per cent. strength. As regards the cause of the disappearance

the sulphurous odour, it may be that a new compound is formed on mixing the two substances. A saturated solution of sodium sulphite contains, at 15 deg. C., 25 parts in 100 parts of water, and its reaction is sharply alkaline. It is found that of commercial sodium bisulphite solution (Poulenc) is sufficient for neutralising 15 ccs. of the saturated solution of sodium sulphite. On adding 1 to 5 ccs. the mixture becomes sharply acid.

In preparing the above S. solution, a saturated solution of sodium sulphite has its alkalinity destroyed by 6 ccs. of bisulphite solution. The other 69 ccs. are, however, free to act as an acid solution. It may be assumed that the sodium sulphite is not decomposed, since there is no evolution of sulphur dioxide; in this case its action would be simply veiled by a small quantity of bisulphite (NaHSO<sub>3</sub>). These two salts would exert on the salts of silver each its separate action, the acid salt preventing the injurious effects which are met with in alkaline develop-

#### FORMULA IIA.

Diamidophenol .....	1 gm.	15 grs.
10 per cent. ammonium bromide solution .....	5-10 ccs.	85-170 mms.
Solution S. ....	7 "	120 minims,
		to begin with.
Bisulphite of soda solution .....	3 "	50 minims
Water .....	150-175 "	5 to 6 oz.

It will be seen that this formula is on all fours with Ia, the only difference being the addition of water, diamidophenol, and ammonium bromide. The only difference is in the sulphite of soda, 7 ccs. of solution S. representing a little less than 1 gm. of sulphite. As for the bisulphite, although these 7 ccs. in about 3 ccs. of bisulphite, this latter is insufficient, and the 3 ccs. is therefore added, which makes the total of bisulphite about 2 ccs. more than in the formula Ia. This latter formula (IIa) is designed for the development of well exposed plates, and the bath is therefore rendered rather more acid and therefore less rapid in action. Yet the bisulphite should be further increased; there is no need to fear markings, if the plates have to be left in the developer a long time in the ordinary dish. In using the formula a plate in a perfectly clean dish is treated with the solution IIa as above, and the plate placed at hand containing 10 to 20 ccs. (½ to ½ oz.) of S. solution. The negative, having been treated with the developer for about half a minute, is covered with a card and allowed to proceed without being again examined for 3 or 4 minutes. Usually the image will be visible at the end of this time.

It should show in a case of great over-exposure, and where over-exposures are prescribed for exposures which, perhaps, have been over-treated. If at the end of 2 to 5 minutes there is no appearance of the image, 2 ccs. (½ dram) of S. solution may be added, and further 3 to 5 minutes given before adding a further 2 ccs., successive additions being made with the object of finding the point at which development commences. This having been found, the subsequent development will be as in ordinary work, and the image will gradually appear, and the final result is an excellent negative with full detail.

This formula No. II., although particularly useful for time exposures, can be employed for all kinds of negatives by increasing within certain limits, the quantity of bisulphite solution. In order to obtain an idea as to the power of the developer in respect, a series of plates were given a normal exposure of 2 seconds at f/6, whilst a few others were given 1-50th of a second on the same subject at the same aperture. The following developer was used:—

#### FORMULA IIB.

Diamidophenol .....	1 gm.	15 grs.
Solution S. ....	10 ccs.	170 minims.
Bisulphite solution (to make 5 ccs. with the quantity already in the developer in the 10 ccs. of solution S.; that is)	3 ccs.	50 minims.
Water .....	175 "	6 oz.

Exposures being dealt with 10 ccs. of the solution S. are

taken at the start, a quantity which would be too great in the case of time exposures. The following results were obtained:—

(1.) No bromide. The time exposures developed fairly quickly, but with grey edges. The instantaneous exposures behaved the same in this bath.

(2.) No bromide, and 5 ccs. extra bisulphite. Time and instantaneous exposures behaved as in (1).

(3.) No bromide, and a further 5 ccs. of bisulphite, 15 ccs. in all. The time exposures came up well, the instantaneous were slow in appearing.

(4.) An addition of 5 ccs. 10 per cent. ammonium bromide solution. Instantaneous exposures go no further, but the time exposures continued developing.

(5.) 10 ccs. of solution S. are added, which brings the bath to a strength of 2 gms. sulphite, 5 ccs. 10 per cent. ammonium bromide, and 15 ccs. bisulphite, which is obviously too strong. In this solution both time and instantaneous exposures developed well. Thus, for an average exposure, at least 10 ccs. of solution S., equal to, say, 1 gm. of sulphite, are necessary. With 20 ccs. of the same solution excellent development of both time and instantaneous exposures can be done together. The necessary bromide, 5 or 10 ccs., should not be exceeded, and the bisulphite should not exceed 5 ccs., especially if one has to work alone without being able to rock the dish. This example will make clear the changes which can be rung upon formula II.

A small proportion of the sulphite-bisulphite mixture gives a very thin and soft negative, whilst 10 to 20 ccs. gives increasing degrees of vigour.

#### FORMULA IIC.

With the exception of instantaneous exposures the following formula will give all that is required:—

Diamidophenol .....	1-½ gm.	15 to 8 grs.
Solution S. (added in 2 ccs. lots to not more than 15 ccs. in all, usually).....	10 ccs.	175 minims.
Ammonium bromide 10 per cent. solution .....	10 "	175 "
Water .....	175 "	6 oz.

As regards the greater quantity of diamidophenol in the above formula, the object of this recommendation is that the use of 1 gm. will relieve the worker from the necessity of keeping the developer in movement. In the case of using the ½ gm., the dish should be gently rocked, and the negatives will then be of a peculiar softness. Deficiency of diamidophenol may give rise to markings, particularly with certain plates. If the 10 ccs. of solution S. are not sufficient to bring up the image in a convenient time additions should be made 2 ccs. at a time.

In the case of portraits taken in a room where the lighting is very often harsh, the quantity of bromide in the formula may be reduced, and a bath used as follows:—

#### FORMULA IID.

Diamidophenol .....	½ gm.	8 grs.
Solution S. ....	10 ccs.	175 minims.
Ammonium bromide, 10 per cent. solution .....	20-40 drops.	20-40 drops
Water .....	175 ccs.	6 oz.

The amount of diamidophenol may be varied from ½ to 1 gm., and more or less ammonium bromide solution used according to the vigour or softness desired. Various changes may be rung upon formula II., which correspond, however, with those of formula I., but differ from the latter in being more amenable to alteration. A point which must not be lost sight of is that the quantity of sulphite determines the greater or less speed with which the image appears. On the other hand, the quantity of bromide, relative to the bisulphite, has a greater or less restraining action on the development. For example, a developer containing 20 ccs. solution S. will work almost with as much vigour as formula I. containing 2 gms. anhydrous sulphite, but in this case the negative will be a little harder.

As has been said before, in all cases of acid diamidophenol development a much shorter exposure can be given. Where

hydroquinone or pyrogallie acid would require a 10 seconds exposure, 2 seconds with diamidophenol will usually be sufficient.

### A Two-dish Method of Developing Time and Instantaneous Exposures.

The following formulæ are employed:—

#### DEVELOPER FOR TIME EXPOSURES.

Diamidophenol .....	1 gm.	15 grs.
10 per cent. ammonium bromide solution .....	5 ccs.	85 minims.
Sodium bisulphite solution.....	3 "	50 "
Solution S.....	10 "	175 "
Water .....	150-175 "	5 to 6 oz.

#### DEVELOPER FOR INSTANTANEOUS EXPOSURES.

Diamidophenol .....	1 gm.	15 grs.
10 per cent. ammonium bromide solution .....	2 ccs.	$\frac{1}{2}$ dram.
Sodium bisulphite solution.....	5 "	85 minims.
Sodium sulphite, anhydrous, powder .....	2 gms.	30 grs.
Water .....	150-175 ccs.	5 to 6 oz.

As negatives are taken from their boxes they are placed in the first of these two baths. If the image appears in 3 or 4 minutes the negative will have been well exposed, and it is allowed to remain in the solution until its removal to the fixer. If, however, nothing appears at the end of 5 minutes the negative has evidently had an instantaneous exposure, and is placed in the second bath. It will thus be seen that development is commenced with a slow-acting bath containing the solution S. to the extent of 10 ccs., equal to 1 gm. of sulphite.

### Diamidophenol for Bromide Papers.

The principles above explained can be applied to developers for bromide and gaslight papers; in fact, for all surfaces on which there is an emulsion of silver bromide. The general rules observed in bromide printing and enlarging, such as the use of slow papers where great vigour is needed and rapid papers, where softness is wanted, are, of course, to be observed when using diamidophenol, as with other developers. A suitable formula is as follows:—

Diamidophenol .....	1 gm.	15 grs.
Sodium sulphate, anhydrous, powder ...	2 gms.	30 grs.
10 per cent. solution ammonium bromide .....	5 ccs.	85 minims.
Sodium bisulphite solution .....	10 "	170 "
Water .....	150 "	5 oz.

In bromide work the same precautions as to the avoidance of dishes which have previously been used for alkaline developers is particularly essential. Development takes place slowly, the high-lights appearing first, then the half-tones, but there is not the slightest fog unless excessive exposure has been given. This is the only cause of failure. Moreover, the developer gives no stains, and the colour of the prints is an excellent black. The only way in which the worker can go wrong is in obtaining a greenish colour on the prints, due to too much exposure. On the other hand, insufficient exposure may give rise to a yellowish colour. One hint which may be given in regard to prints which are slow in reaching the desired vigour is to lay them in the developing bath face down; they are turned over to judge of the progress being made.

### Warm Tones on Lantern Slides.

Gelatino-chloride lantern plates, developed with restrained and weak solutions, are, as lantern workers know, the best means

of obtaining warm tones. A method using diamidophenol has worked out as follows: For an average negative 3 cms. of cesium ribbon burnt at 20 cms. distance from the printing is usually sufficient, and this length of ribbon may be altered, altering the distance from the frame for greater or less exposure. For average good negatives this range of distance is not greater than 5 to 10 cms. for dense, and 30 to 35 for negatives. Ordinary yellow light by an oil lamp or candle may be used instead of any yellow or orange lamp, although, of the incandescent gaslight and similar white artificial light is not permissible, but for these a screen of ordinary white paper may be employed.

The ordinary solution S., already given, is made up in sufficient quantity. The developer consists of:—

Diamidophenol .....	$\frac{1}{2}$ gm.
Solution S .....	8-10 ccs. 135-175 "
10 per cent. ammonium bromide solution .....	10 "
Sodium bisulphite solution.....	5 "
Water .....	175 "

This solution is well mixed, and employed with the precaution that a dish free from previous use of alkaline developer be used. The development at the commencement gives an image of red colour, which changes gradually during development in the direction of sepia. Thus, if one so exposes the colour is too red at the commencement, the right density is reached before the red has been sufficiently removed from the deposit. On the other hand, if the transparency is too black to start with, there is no chance of it reaching a sepia tone at the end of development as regards density is reached. It may be found that while it is possible to force development from red to get the black or greenish-black, one can never work in the opposite direction and obtain red when working from a deposit.

The sepia tones once lost can never be regained again, and are therefore necessary to time exposure correctly, and to work in time. The use of ammonium bromide instead of potassium bromide is of great advantage in avoiding greenish-black colour. These latter arise from a too active bath, whilst the best results are obtained by a long exposure and the use of a fairly active weak bath. Too short exposure will give the greenish-black tone, and it is therefore necessary to adjust the exposure to the character of the developer. In all cases the slides obtained are of very great transparency; the high-lights are absolutely glass, resembling those of an albumen slide. There is no need to back the plate, as is frequently done when alkaline developers are used.

A suitable fixing bath consists of:—

Hypo.....	250 gms.	5 ozs.
Sodium bisulphite solution.....	20 "	3 drs.
Water .....	1,000 "	20 oz.

A little bisulphite solution may be placed in plain water and the mixture used in the case of slides which for any reason have been put aside for any time before being washed. The film is thus sufficiently hardened to obviate the chance of any further softening or undue softening. The formulæ given above have been found very suitable for both the Ilford and Edwards' gelatino-chloride lantern plates.

G. BALAG.

MESSRS. NEWMAN AND GUARDIA have made special arrangements to bring their latest productions amongst the yachting fraternity, during practically all August, and commencing from the date of the Olympic Races, July 27. They have secured a display of the incomparable "N. and G." hand cameras, pocket cameras, and reflex cameras, at the following establishments:—Mr. W. Martin, 112, High Street, Southampton; Mr. Tenison Smith, top of Union Street, Ryde, I.O.W.; Mr. A. W. Debenham, 72, High Street, Cowes, I.O.W. They had a similar display last year at Cowes, which was a great success.

ILLINGWORTH'S SUMMER RIVER PARTY.—The staff of Messrs. I. Illingworth and Co. spent a most enjoyable day on July 11, the occasion of their annual outing. Enthusiastic in play as in work, they made an early start for Richmond, where a steam launch was ready to convey them to Egham. The afternoon was spent at Egham Meads, where numerous sports, some of an extremely character, were indulged in, and, judging from photographs taken the spot and submitted for our inspection, heartily appreciated. An impromptu concert on board enlivened the return journey, the launch reaching Richmond just in time to catch the last train for home.

# HOW TO ADVERTISE A PHOTOGRAPHIC STUDIO.

talk delivered before the Photographers' Association of California at their last convention by Samuel P. Johnston, President Johnston-Dienstag Company, advertising agents, of San Francisco, and reported in our San Francisco contemporary, "Camera Craft."]

direct command, in advertising, is recognised as a power-factor in getting results. Were you to use the direct and in your advertising, it would appear something like

LET YOUR PICTURE TAKEN AT MAHONEY'S.  
or  
HAVE MAHONEY MAKE YOUR PHOTOGRAPH."

suggest the thought of the photograph, and at the time tell the place to have it made. Then there is the suggestion, which is very strong, as applied to advertising, the advisability or desirability of having a photograph to send to loved ones at a distance; or to the features of children or dear ones, that thoughts may continue as one knew them. Children change in size as well as in stature, and it is well to have records at frequent intervals, to the end that their varying cast of countenance or plays of feature may be preserved. How the photographer utilise these facts—reduce them to assets for his business? They are raw materials, as papers, plates, and chemicals—they must needs be handled with skill if you would develop profit out of them. How may they be done to the best advantage?

concentrate your advertising efforts within a close radius of your place of business, cause to be made a list of all the names of the residents therein. If you go about it in the right way, you can learn the names of the members of the family, as well as the address. A clothier in San Francisco, years ago, offered to give something for nothing to every boy and girl who came into the store. They made a card of names, addresses, ages, and sex. These were then grouped according to sex, and also chronologically. Each hereafter they wrote a certain number of letters to as many parents, joggling their memories to the effect that Johnnie or Annie was to have a birthday next Wednesday, and suggesting the purchase of a coat or suit on the Saturday following. It worked like a charm—the expense was slight. Why do the same thing, and it seems to me a thing very profitable to your business.

These cards should have a printed form, and a record should be kept on each by which it may be shown whether a picture has been taken, and the date. Those showing that photographs have been taken should be retired but not destroyed. In a couple of years revive them and write again, suggesting that it is time to have another photograph taken. If you have only the names of heads of families, try a series of postcards on them, one a week for ten weeks. Use the photographs of fine-looking people of different ages. Have the finest possible half-tones made of them. Use the best quality of cardboard; print half-tones over two or three times, using a different tint each time, giving the effect of a photograph. Print the matter in suitable type, and say something—yes, say something worth while. It may require a deal of thinking to find out what to say, but the result will pay. The next week, use a different photograph and different coloured ink—and say something worth while. If you cannot think of anything better, use the direct command, and say:

GET A PHOTOGRAPH  
taken at  
MAHONEY'S.

It would be best to have all these cards prepared in advance, so that the follow-up effect may be maintained.

In a community where there is a newspaper reaching the folks you want for customers, you can develop business through its columns, if you use the right kind of copy and type for display. It is a ticklish thing to get a half-tone printed in a newspaper good enough to advertise a photographer. Better use plain type and depend upon the words and display rather than on a picture.

Those are the things to use to get folks into your place of business. After that is accomplished, the work is only begun. Then your personality counts—your character as a man will attract or repel—will hold or lose customers. Good treatment goes a long way and counts for success or failure almost as much as good work. Your name on the card should be plain and legible. Some photographers are either ashamed of their names, or desire to keep them secret—at least, it would seem so from the style of printing the name on the card.

I am familiar with the amount of money business men may spend for advertising in proportion to the sales in several lines, but not so with photographers. Five hundred dollars would not go very far in a large city, while in a small city that amount would cause a stir.

To advertise anything with success there must be a definite subject—you must not generalise. A. T. Stewart, the famous New York merchant, said: "First get something to advertise, and then make a fuss about it." So with photographers. Confine your advertising to some one thing—something novel or unique, or rare or exceptional, to be found only at the advertiser's. I am a firm believer in contests, as they have proved valuable time and again for almost every line of business. Why not have the photographer offer a prize for the best-looking baby entered in a contest at his gallery, the judges to be some prominent artists of the community? Also prizes for the second and third best. Have cash prizes, and photographs also. Say, fifty dollars to the first, two dozen photographs to the second, and one dozen to the third. All sittings to be made free. Thus will he get a lot of negatives from which the parents will later order pictures, even if baby was not a prize-winner. The same scheme might be worked with beautiful women, but it surely would not be so successful as with children. One photographer might have children of different ages entered, say, from four months to a year in Class A; one year to two years, Class B; two to three years, Class C, and so on. The photographer could get up other contests. For example, he could offer a prize for the best theatrical picture posed by some young lady. That is, the young ladies must appear in costume and be photographed, and the one having the best photograph in the eyes of the judges, would be entitled to first prize.

In all of these cases, make a card record of age and sex of the subject, if possible, as, of course, it would be in the case of children, get the birthday, and then make different sets of cards from the original records. Make one set to be arranged chronologically, and the other to be arranged alphabetically. One of the best means of advertising is a display in a prominent place in front of the place of business, or elsewhere.

Very likely the end would justify the means if you got up very neat little booklets, and left blank pages on which you typed in actual photographs, and sent copies to a selected list. These should then be written to and followed up with letters. Newspaper advertisements used frequently, say, three times a week, should be available in many cases. In these

advertisements all the varied factors of advertising may be used, as: the direct command, the suggestion, argument in favour of good work, or of low prices, as the case may be.

These are, of course, but general suggestions. Individual circumstances must determine the method. The personal letter is a great power in advertising, when it is a personal letter,

and not a circular. Tell the story of your business in a plain way, just as you talk, and keep on telling it from week to week, from month to month. The only medium which approaches the pulling power of the personal letter in advertisement is a personal call. In many instances your personal letter will get an audience when your personal call would not.

S. P. JOHNSTON.

## MEASURING THE SPEED OF PHOTOGRAPHIC SHUTTERS.

ENOUGH has been said about the inaccuracy of the speeds with which shutters supplied to the professional and amateur alike are marked by the makers of these instruments. It is also evident that the speed of shutters alters and varies considerably with time and use, especially in shutters which depend for their accurate movement on a spring. Others, again, vary with the hygroscopic state of the air, on account of the blind or other moving parts taking up water, and they are therefore unreliable. All this shows the necessity for measuring and verifying the speed of photographic shutters in use from time to time. The speed of photographic shutters such as the Thornton-Pickard, in front and behind the lens, or the variety of shutters working between the lens combination, is easily measured by the several devices on the market, or by the timed rotation of a bicycle or perambulator wheel. The difficulty, however, begins with the (most efficient) focal-plane shutters, for testing which instruments elaborate and costly devices have been constructed. The following is a method of testing focal-plane shutters, which can easily be performed by the timed rotation of a wheel, or by

Fig. 1.

slightly altering the rotary devices, sold for the purpose of measuring shutter speeds. In 1903 I wrote a letter to "The British Journal of Photography," in which I advocated the use of a rotating wheel on which two silvered glass balls, or other luminous points, are fixed at or near the circumference of the wheel, diametrically opposite each other. When, however, making actual tests with such a device, it became evident that even the mean of the two movements of the luminous points, with and against the movement of the slit of the focal-plane shutter, gives erroneous results on account of distortion.

By distortion I understand the displacement on the photographic plate of moving points, due to the time it takes for the slit of the focal-plane shutter moving over the whole or part of the plate, not the displacement of a point due to the movement of that point during the time it is actually exposed only. To make this clear I give a diagram (Fig. 1) of an actual test. This diagram represents a print from the plate used during the test. The luminous points are diametrical points on the cir-

cumference of a wheel, or, as in the case of the actual silvered balls on the ends of a straight lath, revolving in the direction of the arrow, and since the image was reversed in camera, the focal-plane shutter which moved in the camera top to bottom actually exposed the image from bottom to top. The slit of the shutter must, therefore, have exposed one of the luminous points, No. 1 first at "a," and during the movement the whole width of the slit point No. 1 has travelled from "a" to "b," but at the moment point No. 1 was exposed by the slit first at "a" the other luminous point No. 2 have been diagonally opposite "a," that is, at "p." The shutter, however, owing to its exposing the bottom of the picture first at the top of the picture, distorted the picture, and the slit exposed point No. 2 at "d." No. 2 point has, therefore, travelled from "C" to "d" during the time the first edge of the (going over the plate or picture) has moved between the parallel lines A B to C D, the arc "c" "d" being quite independent of the movement of the slit of the shutter against or with the movement of point No. 2. Arc "c" "d" is, therefore, a measurement of the distortion, due to the speed of the shutter.

In the test as in Fig. 1 the lath, with its glass balls at each end, moved at the rate of 245 revolutions per minute = 1-1

Fig. 2.

of a second per degree of arc. The width of the slit was 1.1 from this we get  $t = \frac{.001238}{d}$  arc, where "t" is the time exposure in seconds, "d" the distance in inches between parallel lines, A B and C D was 1.72in. - the arc "c" in degrees =  $38\frac{1}{2}$ .

$$t = \frac{.001238 \times 34.5}{1.78} = 1-36\text{th second.}$$

In this test the luminous point No. 2 was exposed very nearly at the culminating point, and moving, therefore, nearly at angles to the movement of the shutter. The arc "d" should, therefore, be nearly a mean of the speed of the shutter. This arc is 50 degrees, or 1-30th of a second.

other test is represented by Fig. 2. In this the distance A B to C D = 1.5in.

$$t = \frac{.001238 \times 62.5}{1.5} = 1.23\text{rd second.}$$

t as per diagram Fig. 1 was taken with a tension of the regulating the speed No. 5, and test as per diagram Fig. 2 a tension of the spring No. 1, hence the difference.

A test of tension No. 10 (the highest tension possible) gave 1.47th of a second, which is nearly double the exposure as given by the makers of the shutter. The width of the slit was always 1.82in.

Since making these tests I have had a new shutter from one of the practical makers, and this shutter gives 1.48th of a second, and the speed is marked as 1.80. It is a pity that manufacturers of shutters should give such erroneous figures.

W. DIESELHURST.

## SOME PHOTOGRAPHIC FALLACIES.

we find a popular weekly, noted for its fiction, gravely misleading its readers, through the correspondence corner of its graphic page, that if a small house is to be rendered as and imposing as possible in a photograph, it should be with a wide-angle lens, we can afford to smile tolerantly. is quite a respectably old fallacy, which many otherwise informed photographers have quoted, or believed in their consciousness, until they have had the actual work to do, have found out the facts for themselves.

is questions seem to furnish opportunity for probably the number of popular mistakes. There is no doubt that the ge worker knows less about his lenses, their properties, the optical laws which govern their action, than he does the other aspects of his craft. This is a pity, for the im- mance of such knowledge can hardly be overstated, and its ment is not at all difficult in these days of cheap practical als.

ch hazy inexactness of statement has been poured forth rning that crowning triumph of the modern optician, the stigmat lens. Frequent inquiries come to hand from per- d individuals who wish to obtain the best lens that money ay, but are doubtful, from what they have heard and read, er, after all, a good rapid rectilinear would not be a wiser ase. If this should meet the eyes of any such, let them be rted with the assured fact that whatever the rectilinear o a first-class anastigmat will do also, and do it better; dition to which, there are many reserve qualities and ad- ges possessed by the anastigmat to which the rectilinear t lay claim. The absurdity of supposing that thousands atical workers would obstinately persist in paying three or imes the price of a rectilinear for a lens that is not so good y needs demonstration.

at long-suffering personage, the lens manufacturer, has yet er grievance in the widespread confusion as to what con- ges effective aperture. Frequently the complaint is made indignant purchaser that his expensive new lens cannot its stated rapidity, because when the diameter of the st stop is multiplied by its reputed  $f$  value, the result is equal to the focal length. That this need not be the case een explained with monotonous frequency, but still the y lives on.

would almost seem as if an apology were needed for re- ing the fact that shutters of identical speeds, as tested, f different makes, do not necessarily give the same expo-

Yet we meet with workers who are puzzled why, with ent hand-cameras in their possession, although these are shed with lenses of the same aperture and shutters of the tested speeds, the negatives taken with one camera are y always fully exposed, while those taken with the other tten under-exposed. The subject of shutter efficiency, as ed by its construction and method of working, and dish- ed entirely from speed, is obviously one with which are as yet unfamiliar.

phenomenon of halation has been responsible for many ge misconceptions. For instance, many photographers

firmly believe that a backed plate will obviate the effect of strong reflections or pronounced lighting in the subject. Quite recently an otherwise thoroughly adept worker was seen making an exposure upon some highly polished silver ware, without any attempt at dulling the surfaces. When it was suggested that the negatives would be sure to show disagreeable reflections, he replied, as though that settled the matter, that he was using backed plates. An explanation, with a hint how to proceed, promptly and gratefully accepted, soon set matters right. The backing, of course, only prevents the reflection of light that has passed through the film to the back of the plate; it cannot remedy strong lights or reflections that occur in the subject itself, which naturally are thrown by the lens, in all their garishness, directly upon the film.

A short time ago the writer had the privilege of seeing a studio in which the light was pleasingly softened by means of pale blue muslin curtains. From an artistic and decorative point of view the effect was charming; but when its originator proudly explained that the intention was to obtain a more actinic light, a friendly argument was inevitable. Fortunately, the operator had some surviving recollections of his early struggles with Euclid, and was open to conviction that a part is never greater than the whole.

Before leaving the studio and its accessories, comment may be made regarding the number of operators who continue under the impression that when a light background is used less exposure will be required than with a dark one, the sitter or subject remaining the same in both cases. On the face of it a plausible belief, this is none the less a grave practical blunder, as a few experiments with the same sitter, but different back- grounds, under similar conditions, will abundantly prove. The light background, it will be found, requires actually a longer exposure.

There is a very general belief that it does not matter whether plates or prints are treated one at a time or all at once in any bath, provided only that the solution is sufficient in quantity and of a given strength. That this is not always so is easily proved by considering, for example, the action of a gold toning bath. If an attempt is made to tone a quantity of P.O.P. prints one at a time, in a dish containing sufficient solution for the whole number, it is found that the first few will tone too quickly, and will soon exhaust the gold, so that the remainder cannot be toned to correspond. Even in development, if enough developer is taken for a dozen plates, and these are developed singly in the same dish, the result will not be so good, especi- ally with the last few negatives, as if they were all developed together, owing to the gradually increasing oxidation of the solution. A practical worker would not, of course, perpetrate either of the aforesaid mistakes; they were merely quoted to provide food for thought, since the principle is one that is often unconsciously violated in other directions.

Another long-enduring example of bad reasoning is to be found in the common practice of painting the developing room some dark or sombre colour. A little consideration ought to show that more light cannot be reflected than is actually there,

and that, so long as the lamp or window is "safe," and stray white light excluded, comfort and ease of working will be promoted by white-washing the walls or painting them in some light colour.

*Humanum est errare!* That being so, it is pleasant to have

to acknowledge, what is certainly true, that photographer body are conspicuous for a generous willingness to place difficulty they have at the disposal of any confrère who difficulty, or seems likely to be. And, as a rule, such advice accepted in the spirit in which it is given. A. LOCK

## PHOTOGRAVURE FOR THE PROFESSIONAL PHOTOGRAPHER

### I.

PHOTOGRAVURE is by far the most beautiful of reproduction processes, and is specially suitable for portraiture, and may be used to advantage when very large numbers are not required. It is, moreover, a process that may be worked by the ordinary photographer without any expensive apparatus, as, with the exception of the dusting-box and printing press, nearly all the necessary appliances will be found in an ordinary photographic establishment. But it must not be supposed that it is an easy process, as difficulties crop up at every stage, and it needs great care and patience if success is to be attained.

The first stage in the process is to secure a perfect and reversed transparency on glass from the negative it is desired to reproduce. If the photogravure plate is to be the same size as the original negative, the transparency is best made by the carbon process, in special transparency tissue, in the usual manner when enlarged negatives are to be made. But if the plate is to be larger or smaller than the original, the transparency may be made by enlargement or reduction in the camera, always bearing in mind that the transparency must be reversed, so that the back of the negative should be placed towards the lens.

If the carbon process is used the glass support must be a little larger than the negative, and must be very carefully cleaned and coated with warm gelatine containing a small quantity of chrome alum or sufficient potassium bichromate to give it a sherry colour. This solution is poured over the plate two or three times, running the surplus off at a different corner, so that the whole of the glass shall be covered. It may then be reared up to dry in a clean rack or standing on a strip of blotting-paper. When dry it is ready for use, but if bichromate is used the plate should be exposed to light. The object is to secure a thin film of gelatine which is partly or wholly insoluble, so that the carbon image will cling to the glass. A small piece of gummed paper should be attached to the uncoated side of the glass to distinguish it, although it is possible to tell which is the coated side by breathing upon it. The film is quite effectual even if of extreme thinness. A number of plates may be coated and stored for future use. The exposed transparency tissue is printed and developed in the usual way, using every care to produce a perfect result, as any defects will be reproduced in the engraved plate.

The copper plate must now be prepared, and the best, most highly polished plates must be used. They can be obtained from the houses that make a specialty of process materials. At first small sizes should be tried at the experimental stages, as failures are inevitable. The plate should be large enough to give a fair margin all round—larger at the bottom of the plate. The first thing is to clean it thoroughly, as it must be free from any suspicion of grease. A ball of whiting is broken up and put into a bottle of water and well shaken until all lumps are broken up. It is allowed to stand for some minutes until the coarser particles have settled, and the water in which the finer particles are floating is poured off into another bottle, which should be labelled "washed whiting," and sufficient ammonia added to make a 3 per cent. solution. A "rubber" will be necessary, and this can be made by taking a long strip of ordinary flannel, about 6in. wide, and rolling it tightly into a firm, stiff roll 6in. long, and tied tightly round and round with string; each end now forms a capital polishing surface.

The copper plate is examined for scratches and any defective one put aside for repolishing. A selected plate is then cleaned with a solution of "American potash" on a piece of cotton wool and rinsed under the tap until the water runs over quite freely, showing no trace of greasiness. The potash is a very powerful alkali, and it must be handled with care, as it will take the skin off the fingers. Potassium carbonate, which will be found now in all photographic

workrooms, will answer the purpose. The copper plate is now dry and with a clean duster, and laid on a sheet of clean paper to keep it clean during polishing. A pool of the washed whiting is poured on the plate and the polishing rubber applied, rubbing vigorously from end to end of the plate. After a time the end of the rubber should be used for a final polish. The plate is then wiped with a clean dry cloth and some zinc white, in powder, is dusted on and rubbed over with clean cotton wool. Finally the white is dusted off, and the plate is ready for the next process—"dusting" or graining. For this a dusting-box is necessary; the local carpenter can make one if a sketch is supplied. It should be lined throughout with thin sheet zinc so that the powdered men shall not cling to the top and sides of the box, and so shall not clog together with damp. A small dusting-box is of use. It should not be less than 2ft. 6in. or 3ft. high by about 12in. square for plates 12in. by 10in. It must be swung on two pivots so that it may revolve freely, and it must be provided with a door to fix it firmly while the plate is being "dusted." Near the bottom of the box there should be a door about 4in. in height and as wide as the box. The recess for the door or lid must

flanges covered with thick rubber sheeting, against which must be pressed by strong springs from a whole-plate printing frame, while the lid itself should have a projecting strip all its edges, lined with rubber, to press against the outside of the box to form a dust-proof joint. It is better not to have hinges on the door; it is more convenient to be able to take it right out of the box. A support for the plate must be provided to raise it about an inch or two of bitumen dust at the bottom of the box. A piece of wood, with a projecting handle and legs to stand on, will answer; the top of the board should be covered with some padding or stuffing about an inch or more thick, over which is stretched some smooth material, such as thin leather. The purpose of the pad is to prevent disturbance of the dust on the plate by vibration of the floor from passing traffic; such vibration would throw the dust into curves and lines. The copper plate should be placed on a piece of plate glass 2in. larger all round than the copper plate, so that the shower of dust is disturbed by the edges of the plate would give uneven grain round the outside. Not less than the finest powdered bitumen is poured into the box. It is obtained from the same firms as the copper plates. Even with the best fitting door the powder will escape a little; it has a penetrating and not very pleasant smell, reminding one of a house in which a large number of cats are kept. Having put in the powder, the plate is fixed in its place and the box swung on its pivots so that the bitumen may fall from one end of the box to the other, filling the box with a cloud of dust. The box must not be turned quite round; the bitumen will swing round and round at one end, and then will be raised, but the box should be turned upside down and then stopped, and the bitumen will be heard to fall

tom; another half-turn and it will fall again, and so on for a few minutes. Then the box is turned right way up and the bolt or catch is loosened to hold it firm, and the top and sides are struck smartly with a cane to shake down any clots of bitumen clinging thereto. After waiting 30 seconds the door is taken out, and the copper plate with the piece of plate glass, resting on the padded board with legs, is very tenderly and gently put into the middle of the box, and the door is just lightly lodged in its place, not fastened, for fear a clot of bitumen should fall upon it. In about ten minutes or more most of the dust will be settled and the plate should be taken out. It will be thinly covered with fine brown dust, and must be handled very carefully, so that the evenness of the coating is not disturbed. When baiting a hook we are told to put the worm on as though we were baiting him, but in dealing with a plate during dusting it should be handled as if it were a dynamite bomb ready to explode by a slight touch. One dusting is seldom sufficient, and a second and even a third may be necessary, especially if a very fine grain is required. The grain must vary according to the subject. A strong subject with large masses of dark shadow needs a strong grain, whereas a subject with delicate tones are to be reproduced, such as a lady in a white dress, needs a fine grain. When a fine grain is required, three dustings or even four may be necessary, as the dusting-box must remain for a longer time at rest before the plate is inserted. So that if a minute is allowed before the plate is put all the larger particles of bitumen will have fallen, and only the finest dust remains to fall upon the plate. It may be well to explain at this stage the necessity for the "grain." The photogravure plate, when ready for the printer, may be compared to a mezzotint plate; as a matter of fact, it is printed in exactly the same way. A mezzotint is made by roughening a copper plate with a tool shaped like the rocker of a cradle; the curved side is covered with fine teeth, and the tool is rocked all over the plate, causing a multitude of fine holes with burrs; and if it were covered with ink

and printed at this stage the impression would be a fine velvety dark tint. In this state the engraver takes it in hand and scrapes away the rough surface, according to the lightness of the tone he wishes to produce. Bright lights are scraped until a smooth copper surface is left, and the brightest spots of light are burnished with a steel burnisher. Such a plate is printed by filling the fine holes produced by the rocker with ink, which is of about the consistency of butter. The plate is warmed to make the ink flow slightly. It is rubbed vigorously into all the depressions in the plate and the surplus is wiped off, at first, with cloths, and a final polishing is given with the palm of the hand. The margins are then wiped with a rag which has been rubbed on a ball of whiting, to remove all traces of ink and leave margins without any tint. The plate is then ready for printing. It is laid on the bed of a press, a sheet of damp paper is laid upon it, several thicknesses of cloth known as "blankets" are laid upon the plate, and it is drawn through the press. The "blankets" give an elastic pressure upon the paper, and force it into the depressions in the plate, picking up the ink they contain.

A photogravure plate is just like a mezzotint in printing, but there are no fine holes and burrs to hold the ink, and the shallow depressions, representing the shadows, would be wiped almost free from ink when removing it from the high-lights, so that by covering the plate with fine particles which resist the etching fluid we secure in the shadows innumerable spikes or points which retain the ink. It will be easily understood that where there are broad masses of deep shadow these points must be larger than in subjects of a more delicate character, for the etching solution eats away the copper, not only downwards, but sideways as well, and in a deep shadow the mordant would eat its way beneath the dots of bitumen if they were too small. It would be a great gain if a discriminating grain could be used which should be coarse in the shadows and fine in the high-lights.

HAROLD BAKER.

## BRUSH-TONED PORTRAITS IN DIFFERENT COLOURS.

[Several portraits having been sent us of late with the request for information as to their method of production, we have replied that the specimens were evidently the results of local chemical toning. Although the results were by no means pleasing from an artistic standpoint, they are evidently in demand among certain classes of sitters, and therefore the following notes from the "Bulletin of Photography," Philadelphia, professing to describe the practice of a similar method may be quoted.—Eds. "B.J."]

As far back as 1864 we find mention of multiple tones by modification of the gold bath alone; the flesh tints possessed a degree of naturalness and the hair and clothing were approximately represented as in the original subject. Not long ago Dr. Raubert, of Germany, revived interest in the process by exhibition of beautiful artistic work. We will draw on his experience and describe in detail his method. The result in P.O.P. is to be strongly printed, thoroughly washed as in the usual manner, then placed while still wet face up in a shallow porcelaine dish or upon a sheet of plate-glass previously cleaned most scrupulously. It is now ready for the multiple toning operation. For this purpose prepare three different toning solutions, a gold, a uranium and a uranium bath.

With the gold bath we can have, according to the duration of the action of the toning, brown, sepia, violet, purple, bluish black and black.

With the second blacks and greys, and with the third red and flesh tones. The toning is effected locally by means of brushes, which should be soft, preferably sable, and without any metallic mountings. They should be of various sizes.

To make the gold bath, that is for browns, violets, purples, sepias, take

Water .....	4 ounces.
Borax .....	15 grains.

Just before using add 1 drachm of gold solution constituted as follows:—

Gold chloride .....	2 grains.
Water .....	1 ounce.

The constitution of the platinum bath is:—

Water .....	16 ounces.
Potass. platino chloride.....	15 grains.
Phosphoric acid .....	1 drachm.

Constitution of the uranium bath:—

(A) Water .....	4 ounces.
Uranium nitrate .....	15 grains.
(B) Water .....	4 ounces.
Ferricyanide potassium .....	15 grains.

Mix just before using.

If we have a portrait to operate upon, begin by toning the background with the gold bath, taking care not to encroach upon the lines of the face or hair. After the proper tone is reached, and you have quite a selection to choose from, from brown to blue—wash the print as you do an ordinary toned print, that is to stop further action of the toning solution.

Next comes the hair; if this is to be auburn, allow the bath to ripen a little, that is, use one which has been previously used and a few days old. For deep brown hair use stronger gold bath, that is, add a little more gold, but be careful to neutralise the bath if the excess of gold destroys the neutrality. Add a little more of solution or borax. Black hair is obtained by toning first with the gold and following with the platinum. When the proper degree in the toning is reached wash under the tap.

Now fix the print before you try for the toning of the flesh or before you use the uranium bath. The drapery, of course, may be toned with any of the baths, but if red tones are wanted you must defer the toning until the fixing is accomplished. After fixing you still employ the gold bath if necessary to strengthen up certain parts, but not the platinum. The pupils of the eyes may thus be intensified.

Use the uranium bath last after the fixation. Do not let it remain on the parts too long else the spot will be toned too deeply.

Wash finally to print for half an hour and the work is complete.

Blue, yellow and green tones may also be secured by use of other chemicals, but the results are by no means as rich and satisfactory as those had by the method given above, which are admirable for portraiture.

## DEVELOPING AND PRINTING FOR AMATEURS.

In these days of keen competition the professional photographer, no matter how select his business, cannot afford to neglect or despise any work that brings a little "grist to the mill," so long as such work is within his compass and does not infringe upon the rights of other businesses or professions.

There is no doubt that in the past, as well as in numerous instances in the present, the branch of work which heads this article has been neglected by those to whom rightly it belongs, or, if not neglected, it has been taken up half-heartedly or in anything but an enthusiastic spirit.

The reason of this is pretty obvious. Professionals, in the first instance, strongly resented the claims and work of the "amateur," and if he brought his exposures to be developed or his negatives to be printed he was received with anything but an open-armed spirit, and he was given to understand that such work was not required or such a high price was charged that his future visits were few and far between.

It is not surprising, therefore, that all over the country the photographic dealer has taken up this work, and the amateur but rarely visits the photographer, except in cases when he requires some very special work, such as retouching, spotting, etc.

Anyone taking up this work for the first time must not hope or expect to get high prices. The days when 3s. for developing one dozen quarter-plates was obtained has gone, and although similar prices are still quoted in a few lists they are the exception rather than the rule.

A fair price, and one which pays, as I shall presently demonstrate, is for films, one penny per exposure any size, and for plates 1s. 6d. per dozen for quarter-plates, and 2s. per dozen for half-plates.

The price for printing is rather higher, and generally 2s. a dozen for quarter-plates, and 3s. for half-plate prints can be obtained.

At the above prices I can quite understand that many photographers will hold up their hands in pious horror, but money can still be made even under such conditions. Films, for instance, can be very quickly developed and fixed, for, as they are passed through the developing solution in the length, the under-exposures or over-exposures being cut out for separate treatment, a very considerable number can be finished in an hour. Plates, except when but two or three are required, can be developed by the "stand" process, a 1 in 1000 solution of rodinal being found all that is necessary, with a time limit of three hours. A quick developer is required for films, and the metol quinol formula satisfies in this respect the most exacting. A good one is as follows:—

No. 1. Metol .....	2 drams.
Hydroquinone .....	8 drams.
Sulphite of soda .....	6 ounces.
Water .....	10 ounces.
No. 2. Sodium hydrate .....	300 grains.
Water .....	10 ounces.

For use, take half an ounce of each solution, and add two ounces of water, making three ounces in all. This is an exceedingly active developer. Detail is all out in about fifteen seconds, and development is complete in two minutes, and as most of the ordinary amateurs' negatives are under-exposed, a "quick" solution such as this is a great boon.

A word of caution is, however, very necessary. It will be wise to pass the strip of film through water several times before placing in the above, or markings may appear, due to unequal development. It is quite possible to develop and fix twelve six-exposure films by the above method in an hour, and this work, if charged for at one penny per exposure, is not unprofitable, and can be undertaken in one of those spare half hours which even the busiest sometimes require to occupy.

There is one virtue very necessary in working for amateurs, and that is promptness. He or she is generally very anxious to see the result of their labours, and it is a good plan to develop all films and plates the same day as received. Printing, of course, will take longer, but even this should not be allowed to wait too long before undertaking.

As regards this, the quicker method is to use gaslight papers, and the amateur, as a rule, prefers to the ordinary printing-out varieties. Two speeds should be stocked—the one, slow and vigorous, for thin negatives; the other fast and soft, for hard and contrasty ones. The use of an acid fixing bath reduces the risk of stains to a minimum.

Catering for amateurs in this way often brings more professional work in its train, for it is still a fact, borne out by general experience, that when he or she requires a portrait or anything special visit is paid to the man who, by his training and experience, is most capable of producing it.

Finally, it is not suggested that a fortune will be made by any of the above methods, but that an income, small perhaps, but for certain, is assured, and such none can afford to neglect under present circumstances.

ERNEST C. CRISP

## Photo-Mechanical Notes.

## The Asphalt Process of Half-Tone Lithography.

Writing in the current issue of "Photographische Korrespondenz" Professor August Albert refers to the special practice requiring the employment of a sensitive asphalt solution for direct prints on grained lithographic stone, the usual mistake of most operators being in giving too heavy a coating. If the work be done in a room in which the air is warm and dry much greater difficulty is encountered, for the reason that the film dries very quickly, and, particularly in the case of large sizes, is not evenly distributed over the surface. This too rapid drying can be prevented by a considerable addition of oil, Peruvian balsam, and similar substances, but the strength double that of the usual formula—3 per cent. to 100 parts—should not be exceeded, as otherwise the developed image will not have the sharp outline which it otherwise would, and the print will be dirty and veiled. After numerous experiments with different preparations, the following process has been found to be faultless and uniform films after a little practice, even on the largest sizes of work. The asphalt solution is as follows:—

Purified asphalt .....	24 gms.
Lavender oil .....	18 gms.
Benzole .....	100 ccs.
Turpentine (pure French) .....	25 ccs.

After complete solution of the asphalt, which generally requires vigorous shaking, a kind of varnish is produced, which is without filtering, a portion corresponding to the size of the stone to be prepared being poured on to a clean colour slab, distributed with a smooth composition or leather roller and immediately transferred to the stone, after the manner of transferring the colour in tone-printing of large sizes. As experiments have shown, the sensitivity of the film does not suffer in the slightest; for later a pure medium strength lithographic varnish or Venetian turpentine has been used in place of the lavender oil, as the application of oil film is thus rendered easier. After the usual lithographic retouching the stones are given a "still etching," as in litho chalk drawing, and are then allowed to dry. This etching is quite sufficient for obtaining a preliminary print. The stones are then washed with water and inked up with black ink on top of the asphalt image that is, without washing out with turpentine—and again etc. A number of preliminary prints—about ten to twenty—are taken off, with the ink required on top of the black ink, until the image comes off clean. For storing, the remainder of the coloured ink is taken off on paper and a few prints made with transfer ink in order to be able to replace the ink already used by a transfer ink without having to wash out the stones with turpentine.

The annual outing of the staff of Messrs. W. Butcher and employees at Camera House and the works at Copenhagen and Blackheath took place on Saturday, July 18. The party, numbering about 180, spent a very enjoyable day, the rendezvous being the Dumb Bell Hotel, Taplow. In a speech at luncheon, Mr. Butcher referred to his brother, who had on previous occasions taken great interest in these outings, and a hearty message of farewell was sent him in China, where he is now travelling. A very pleasant afternoon spent on the river, tea was taken there and the sports in connection with the Camera House and Club were held.

\* For colour printing the stone should be washed out on the top of the ordinary asphaltum washing out solution.

## Patent News.

*process patents—applications and specifications—are treated in the Mechanical Notes.*

The following applications for patents were received between 6 and July 11:—

**APPARATUS.**—No. 14,415. Improvements in apparatus for reproducing the motions of a moving body at a distance and indicating instantaneous position. Arthur Hungerford Pollen and Harold Herwood, 188, Fleet Street, London.

**ROLLS.**—No. 14,489. Improvements relating to photographic roll reels and fittings therefor. Magnus Niell, 88, High Holborn, London.

**DEVICES.**—No. 14,490. Improvements relating to roll-film loading devices for photography. Magnus Niell, 88, High Holborn, London.

**COLOUR PHOTOGRAPHY.**—No. 14,586. Improvements in or relating to colour photography. Charles Frederick Emil Fenske, Chancery Lane Station Chambers, London.

**TRIMMER.**—No. 14,653. Print or mask trimmer. Frank Baker, 5, Ednam Terrace, Old Lodge Lane, Purley, Surrey.

**LENSES.**—No. 14,673. Improvement in photographic lenses. Conrad Beck and Horace Courthorpe Beck, 68, Cornhill, London.

**MIXTURE.**—No. 14,692. New and improved mixture for flash-lights and the like and method of producing the same. Carl Hage, 111, Hatton Garden, London.

**APPARATUS.**—No. 14,757. Daylight developing apparatus for photographic plates, films, and the like. Edmund Hodgson Smart, Southampton Buildings, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**SENSITIVE PRINTING MACHINE.**—No. 2,076. 1908. The sensitive paper is first coiled upon a roller, 1, is drawn by means of a table band delivery in front of the source of light, 2, and is thereby exposed. The introduction of the original to be copied takes place simultaneously from the supply table, 3. The guiding of both parts is effected by means of a loose band, 7, passing round rollers 4, 5, and 6, which stretches opposite the source of light around a curved transparent plate, 8, and draws between

the sensitive paper and also the original to be copied placed upon the same. The passage of the negative of the sensitive paper at the rear of the plate 8 is effected only by the friction with the band, 7. As the plate is smooth at the back, it is found in practice that this friction alone effects a completely regular transmission of the paper. For the more uniform and intense distribution of the light a mirror, 9, is provided. The paper, thus placed with regard to the original, has

passed the illuminating plate, the original is taken off from the sensitive paper by means of a scraper, 10, and received in a container, 11. The taking-off of the original is aided by a sharp bend of the transporting strap round the roller, 6. For the tightening of the forwarding band, 7, and for the passage thereof past the plate, 8, there is further provided a special counter-roller, 12, which rests firmly upon the roller, 6, and thereby ensures an unconditionally certain motion of the band. The exposed paper passes between the rolls 6 and 12, away on the forwarding band in a sloping direction downwards to the developing mechanism.

Over the rolls 13, 14, the drying cylinder, the rolls 16 and 17, there pass at both sides travelling bands, 18, for the purpose of conveying the paper strip. This is secured or clamped fast between two flat pieces, 19, 20, lying one upon another, and the ends of these pieces are held together by a shoe, 21, passed over them. These shoes are provided with hooks, 22, which can engage in carrier pins, 23, arranged on the strap, 18. Upon the motion of the strap, 18, there will consequently follow a motion of the sensitized strip, 24, as shown in the figure.

The illuminated and still dry paper is then wetted by means of a tube, 25, and a support is provided for the wet paper, because while in this condition there is considerable risk of the paper being torn, and in any case it would hang down considerably. To prevent the adhesion of the wet paper to this support the latter is provided with a series of thin rollers, 26, over which the paper is fed. The strip passes then further into a washing basin, 27, over the rollers, 14, placed in it. After passing a squeezing device, 28, the strip passes to the drying cylinder, 15, which is heated internally. Passing around this cylinder, the paper moves on over the rolls 16 and 17 to the winding roller, 29.

Before the machine can commence working a portion of the paper wound on the roller, 1, has to be led completely through the whole apparatus. The course of the paper is from the roll, 1, behind the transparent plate, 8, round the roller, 6, between this latter and the counter roller, 12, down over the rollers, 5 and 13, on to the travelling bands, 18, where the paper end is secured between the pieces, 19 and 20, over the rollers, 26, round the roller, 14, through the squeezing device, 28, over the drying cylinder 15, round the rollers, 16 and 17, on to the roller, 29, where the clamped end of the paper fits into a suitable slot in the same. Thus it will be seen that the sensitive strip itself forms the connection between the various parts of the whole apparatus. Jakob Röttgen and Julius Frey, Klettenberg, Cologne.

**EXPOSURE INDICATORS.**—No. 19,902. 1907. This invention has reference to apparatus (for the purpose of preventing double exposure of photographic plates) in which the shutter is locked to the dark slide, when it is "closed" after exposure of a plate. The object of the present invention is to provide a device of this kind which is simpler in construction, has fewer working parts, and is quite as positive in action as those heretofore proposed.

In the annexed drawings Figs. 1, 2, and 3 are respectively, side elevation, end elevation, and plan of a shutter locking device.

Fig. 1.

Fig. 2.

*a* is a dark slide of the usual pattern, and *b* is its shutter. Screwed to slide *a* is a small piece of sheet metal *c*, having an upstanding flange *d* undercut at *d*<sup>1</sup>, and an upstanding flange *e* disposed at right angles to *d*; *f* is a spring plate firmly screwed to the shutter at *g*, but movable on screw *h*, the head of which constitutes a stop to limit its outward travel.

When the slide is loaded in the dark-room, the user, in closing

it, moves the spring plate *f* by the finger, so that its free end is outside the flange *e*. (See Figs. 2 and 3.) The shutter *b*, on being drawn to expose the plate, the spring *f* (being freed from flange *e*) moves to its normal position, close to the shutter. Then, when the shutter is pressed inwards again, after exposure of plate, the spring first moves into contact with the edge of flange *d*, is pressed outwards a little by the contour of same, passes down between the flanges *d* and *e*, and springs into the recess *d*<sup>1</sup> of flange *d*. The shutter is now closed, and cannot be opened until the spring *f* is purposely moved by the finger clear of the flange *d*. Samuel Lowe, 26, Market Square, Shirebrook, Mansfield.

**STUDIO STANDS.**—No. 20,057. 1907. The base of the stand may be constructed in the usual manner, that is to say, it may consist of an upper and lower circular table, to which three legs are attached. The holes in the tables are triangularly shaped to receive the sliding pillar, which is of a triangular section. Between the tables is suspended a vertical swinging arm, carrying a roller at its free end. The arm, which is preferably hinged to one of the tables, exerts (by means of a spring) a pressure against one face of the triangular pillar sufficient to keep the other two faces in close contact with the corresponding faces of the holes in the tables, the roller preventing any undue binding and allowing the pillar to rise and fall smoothly.

A means is sometimes provided for adjusting the spring controlling the swinging arm according to requirements, and the ordinary worm wheel and rack gearing is employed to regulate the height of the camera. But if the stand is required only for carrying a light camera, the gearing and spring arm is dispensed with, and an eccentric gripping device substituted, consisting of a substantial spring metal arm, hinged to the upper surface of the lower table near its outer edge. The arm projects inwards towards the triangular pillar, against which its free end rests at an obtuse angle, and in such a manner that the weight of the pillar and the camera causes the arm to bind, by an eccentric thrust on the pillar, which drives the latter towards the bearing surfaces of the holes in the tables, as formerly described.

When it is desired to lower the pillar, the spring arm is raised by the hand or otherwise, whilst the pillar is allowed to slide downward, and is immediately gripped when the arm is released, the latter offering no resistance to the upwards movement of the pillar.

In both methods a metal strip is fixed on the triangular pillar to take the stress of wear. Thomas Percival Woolfe, 34, Upper Street, Islington, London.

**PORTABLE FLASH PORTRAIT LAMP.**—No. 19,333. 1907. The invention consists of a chamber of fireproof fabric within which a charge of magnesium powder is burnt. The chamber is made collapsible. Joseph Leclerc, 69, Boulevard de la Rochelle, Bar-le-Duc, France.

**TELEGRAPHIC TRANSMISSION OF PICTURES.**—No. 27,570. 1907. The method described in the present invention consists in the use of a pencil of cathode rays acting upon a fluorescent screen. These rays, as is well known, are capable of being easily controlled by an electrical or magnetic field in such a way that they follow the alterations or fluctuations without any delay or sluggishness.

In order to produce the complete picture, successively, point for point, the point on the screen (upon which the pencil of cathode rays acts) is first displaced to correspond to the displacement of that point in the plane of the picture or field of view to be portrayed from which the rays acting for the time being in the transmitter proceed. Such displacement is caused by the action upon the pencil of cathode rays of a suitably varying magnetic or electric field; and the intensity of the action of this pencil of cathode rays upon the fluorescent screen is altered according to the degree of brightness at the time being of the point of the plane of the picture or field of view to be portrayed.

This double influence can be effected in the following way for example:—At the transmitting station the rays or pencils of rays proceeding from the various points of the plane of the picture or field of view are thrown on to a photo-electric receiver by means of an optical system which receives two movements, each independent of the other, in two co-ordinate directions. These movements can be effected by rotary movements of mirrors or by oscillatory movements of mirrors or lenses, or by a combination of rotary and oscillatory movements of similar parts, or by any

suitable movements of an optical system, in any case, the arrangement being such as to successively direct the pencils of light rays proceeding from the various points of the plane of the picture field of the view being portrayed on to a photo-electric receiver whereby the movements of the optical system simultaneously cause the formation or alteration of electrical, continuous, alternating polyphase currents or of electromotive forces which at the receiver station set up or influence two corresponding components of magnetic or electric field which in their turn move or vibrate pencils of cathode rays. These components must be such that the resulting movements of the pencil of cathode rays, and consequently therefore the movements of the luminous point produced there upon the fluorescent screen also, correspond to the movements or displacements of that point in the plane of the picture or field of view which is to be portrayed at the time, which displacements arise during one or other of the independent movements of the optical system.

The electrical currents or electromotive forces before mentioned may be produced at the transmitting station by inductors which execute the same movements as the movements of the optical system or they may be acted upon by rheostats, the resistances of which are automatically varied according to the movements of this system.

The variation of the brightness of the luminous point produced upon the screen by the pencil of cathode rays to correspond to brightness of the point on the plane of the picture or field of view which is to be portrayed, may be effected by subjecting the pencil of cathode rays, before it comes within the influence of before-mentioned magnetic or electric field, to the deflecting action of another electric or magnetic field, the intensity of which depends upon the current, or the electro-motive force, generated or varied by the photo-electric element which is influenced by the pencil rays issuing from that point of the plane of the picture or field of view which is to be portrayed, at the time. Under the action of this deflecting field the pencil of cathode rays is partially reflected back by an impervious screen and its intensity is consequently more or less reduced. Boris Rosing, Technological Institute, Petersburg.

**CINEMATOGRAPH MECHANISM.**—No. 5,336. 1908. The invention consists of a cinematograph apparatus provided with a removable film box, which can be inserted into the casing containing motor and film moving mechanism. The film guiding mechanism is arranged outside the film box, and the latter is constructed with two apertures for the passage of the film to and from the guiding mechanism, shutters being provided to close these apertures when the film is traversing the same. Alberto Lleó and Pablo Audou, 35, Paseo de Gracia; and Claudio Baradat, 89, Paseo de Gracia, Barcelona, Spain.

The following complete specification, etc., is open to public inspection before acceptance under the Patents Act, 1901:—

**PLATES.**—No. 13,999. Packages for photographic plates or films in means for the successive exposure of said plates or films. Optische Anstalt C. P. Goerz, A.-G.

## New Trade Names.

**WARPRESS.**—No. 302,941. Photographic chemicals and dry plates included in Class 1. George Nelson, Dale and Co., Ltd., Elms Mills, Wharf Street, Warwick, manufacturers of gelatine. 11, 1908.

**BRILLAC.**—No. 303,769. Chemical substances used in manufacturing photography, or philosophical research and anti-corrosives. Produits Chimiques de Croissy, Ltd., 29, Rue de Rome, Paris, France, manufacturers. June 6, 1908.

THE "RAJAR" CAMERA, offered monthly by Messrs. Rajar (Limited, Moberley, Cheshire, for the best print on "Rajar" P.C. has been awarded to Mr. J. W. Leake, 2A, Dulverton Road, Leicester the print having been judged the best during June. The paper on which the print was made was purchased from Mr. A. Newton, 1 Street, Leicester.

## Analecta.

Extracts from our English weekly and monthly contemporaries.

### Ortol-Soda Developer.

Mr. C. H. Hewitt (writing in "The Amateur Photographer and Photographic News" for July 21) gives the following directions for use of ortol-soda developer:—

ORTOL-SODA.		
(A) Ortol—Potass. metabisulphite .....	35	grs.
Cold water .....	10	ozs.
Ortol .....	60	grs.
(B) Soda—Sodium carbonate .....	1½	ozs.
Sodium sulphite .....	1½	ozs.
Water .....	10	ozs.
(C) Bromide—Potass. bromide .....	½	oz.
Water, up to .....	5	ozs.

These solutions the developer for use is compounded as follows:

	Flat subject or Full exposure or Vigorous negative.	Normal subject or Normal exposure or Normal negative.	Contrasty subject or Short exposure or Soft negative.
(A) Ortol ...	1 oz.	1 oz.	1 oz.
(B) Soda.....	1 oz.	1 oz.	1 oz.
(C) Bromide ..	6 minims	3 minims	none
Water...	none	1 oz.	4 oz.

For those who desire to work factorially, it may be well to say the appearance is somewhat more rapid than with pyro-soda, under normal conditions, that is, taking a developer mixed according to the centre column, will be about twenty seconds, the time of development for a contact bromide negative being about one and a half minutes. These figures have been obtained with considerable frequency in developing recent exposures, and agree with factor of 10, which is that given by Watkins.

### About Changing-Bags.

Changing-bags (says a writer in "Photography and Focus" for 21) may be divided into two kinds—those which are provided eye-holes, so that the photographer can see what he is about, those which are not. The latter are very much simpler to make, in actual use are quite as handy as the former, as the "seeing" is a best a poor affair, and should really not be necessary. The writer used both, but the simpler form is what he prefers on all grounds, as that described below.

The first proceeding was to make three separate bags, like pillow cases, just sufficiently different in size to enable them to slip one over the other. The outer bag when laid flat on the table I find measures 29in. by 17in. One end of each bag is closed and the other open. Near the closed end of each bag, on one side of it, is sewed a sleeve of the same material 9in. long, and just large enough to pass easily over the hand. When the three bags have been made they are placed one inside the other, and are stitched together at the mouth of the bag and at the end of the sleeve, and nowhere else. This is important, as we must have no pin or needle holes through any two of the bags in the same place. The sleeve is made with an elastic to close round the wrist, and the mouth of the bag is doubled over and provided with cords, by which it can be fastened in the same way.

INTERNATIONAL EXHIBITION OF PHOTOGRAPHY will be held during the summer of the present year at Kiev, under the auspices of the Imperial Russian Technical Society, which has its headquarters in that city. The exhibits will include examples of pictorial colour photography and lantern slides, scientific, and technical photography, the last section being devoted to photographic processes and trade exhibits. Full particulars and entry may be obtained from the secretary, Mr. S. T. Horovitz, Technical Society, Kreshchatik, 10, Kiev.

## New Books.

"The Photographer's Handbook." By Charles Harrison and John C. Douglas. London: John Lane. 3s. net.

This volume is one of the "country" handbooks which Mr. Lane has issued from his press at the Bodley Head, and those who know the previous numbers of the series will readily agree with us that, in the matters of type setting and printing, there is no elementary manual of photography which approaches it. As regards the text, we cannot say that the authors exhibit any exceptional qualifications for their task. They express themselves clearly, and we cannot accuse them of misleading the reader on any points. But what they say has been said in scores of handbooks before, and has frequently been made the subject of more comprehensive treatment in a smaller space than it obtains here. On the other hand, we would do the authors (or one of them) an injustice if we omitted to mention the reproductions of the very excellent selection of photographs which illustrate the volume. The subjects include such extremes as seashore figure studies, harbour scenes, sheep grazing, fishing boats in a gale, portrait studies, sunset effect at sea, sea gulls, still life, the open sea, and a nude study, every one of which, without exaggeration, is an excellent example of first-rate technique, and must needs be an impetus and an example to the reader of the book. The half-tone reproductions are done in the best style, and "The Photographer's Handbook" is thus the only elementary manual of photography which is also nice enough in appearance to form a gift-book.

Kolloidchemie und Photographie. By Dr. Lüpcke-Cramer. Dresden: Th. Steinkopf. Mk. 5.80.

There is sometimes a danger in scientific matters of explanations being mere forms of words. To call a mysterious reaction "colloidal" may be comforting, but it is not necessarily illuminating, and it may be that the word "colloid" will disappear when the phenomena termed colloidal are better understood, or, like "latent heat," will remain as a memento of imperfect understanding. In this connection it may be well to insist that Graham's fundamental distinction between crystalloid and colloid matter can no longer be considered as sound. Rather should we say that these terms stand for general states of all matter according to the conditions. Meantime, one welcomes every thoughtful contribution to this most vexed branch of chemistry, and to photographic chemists Dr. Lüpcke-Cramer's work should prove of great value and interest. It is divided into two parts, an introduction to colloid chemistry, which does not pretend to be exhaustive, and an epitome of the author's own applications to photographic problems. A short description is given of the chief properties of hydrosols or colloid solutions, with extracts from Graham's original memoir. Following this are sections dealing with Van Bemmelen's researches on the nature of gels, and Böttcher's on the structure of colloid bodies. The second part contains Lüpcke-Cramer's own special applications of colloidal chemistry to photographic problems, the preparation of colloidal silver, and of the colloidal silver halides. The basic matter for photography is described, although this is dealt with more fully in the work next noticed. There then follows the part played by adsorption in photographic processes—viz., in the formation of the latent image, of the developed image, in the retention of salts by gelatine and the finished image, and in the tanning of gelatine and other organic colloids. It may be said of all the problems that the author has dealt with them in a most suggestive fashion, if not always conclusively. One could wish, however, for a more systematic and orderly exposé of results and methods; in writing of colloids it is not necessary that the style be colloidal too. The author brings weighty evidence to support the view that the photo-halides are nothing but "adsorption" compounds of colloid silver with silver halide, and that the latent image is also of this nature. It is questionable if it is correct to term the substance of the developed image, as also of the amorphous silver halide, a "gel." The solid coagula obtained by throwing down a "sol" or colloid solution probably differ very much from true gels, such as that of gelatine. But Cramer's experiments throw much light on the complex nature of the photographic image after development, after primary fixation, etc. Very interesting is the section dealing with the tanning of gelatine by heavy metallic salts, which is attributed

to the formation of colloid complexes or adsorption compounds between hydrolysed hydroxide and the gelatine. The work should be studied by every photographic chemist who desires to see what "the chemistry of the future" has to do with his special province; it is clearly printed with some good microphotographs, and printing errors are few. There is a name index, but none to the subject matter.

Kolloides Silber und die Photohaloide. By Carey Lea und Lüp-  
Cramer. Dresden: Th. Steinkopf. Mk. 4.80.

This is a German reprint, compiled and annotated by Dr. Lüp-  
Cramer, of Carey Lea's investigations on colloidal or soluble silver and the coloured silver haloids—silver haloids darkened by light or photo-haloids, as Lea first termed them. These must always be of fundamental importance in photographic chemistry, and, scattered as the American investigator's writings were, photo-chemists owe considerable thanks to Dr. Cramer for collecting and editing them. It is to be noted that Cramer dissents from the "subsalt" theory of Carey Lea as unnecessary, and that Lea's use of "allotropic" practically coincides with the modern use of "colloid." The book contains a biographical notice of Carey Lea, and some notes, then follow Lea's own work on the combinations of the silver salts, and the production of the "photo haloids" by chemical means. That the detailed description of the reactions is by no means superfluous, every worker in colloid chemistry will acknowledge. The book extends to 147 pages, and is uniform in production with that noticed in the foregoing.

"How to Make Oil Prints by the Rawlins Process." By Robert  
Demachy. London: James A. Sinclair and Co. 6d.

This book, of course, describes M. Demachy's own method of working the oil process, but his advice is obviously sound, and will appear to be so even to those not acquainted with his work, if there be any such benighted persons. He lays great stress on the importance of a good negative and of correct exposure, and his method of determining exposure with an Artigue actinometer is very simple and well worth adoption. Throughout he is very particular and precise in the preparation of the print, and he does not believe in relying on the pigmentation to correct faults in exposure. He says: "It is all very well to talk about control and local inking, but control and local inking can only be used with an obedient film, and the film is obedient only when its surface offers the maximum quality of love and distaste for greasy ink," which condition requires a special degree of exposure. The beginner is specially warned *not* to use his muscles when pigmenting, and it is pointed out that the pigmenting action is not an athletic pastime, but requires a delicate touch that is only mastered by practice. M. Demachy's advice is supplemented by a few practical notes by Mr. James Sinclair, and the booklet is just what the oil-printer should have at his hand, since it gives the advice of a master-worker without unnecessary words.

"The Eye: Its Elementary Anatomy, Physiology, and Optical Con-  
stants." By Lionel Laurance. London: The Orthos Press.  
3s. 6d.

This is an excellently arranged and very useful little text-book on the eye, and it contains many items of information that are not to be found in many other more ambitious works. It should be of great use to all students of optics and the eye, but it contains nothing of any importance to photographers. Binocular and stereoscopic vision are only very briefly touched upon, and these are about the only subjects concerning vision that the photographer is generally interested in. There are, however, some interesting specimens of photomicrographs by Prof. Dimmer of Graz and Dr. Lindsay Johnson.

"THE SCIENTIFIC MONTHLY."—The first number of a new periodical dealing with physical science from a popular standpoint makes its appearance under this title, and is published by the proprietor, Mr. Arthur N. Kemp, 26, Shaftesbury Avenue, W. The issue deals with astronomy, chemistry, microscopy, and wireless telegraphy. It also contains reviews of new apparatus. We cannot say we care much for the "scrappy" paragraphs used to fill up odd corners. An example is: "The photographic plate fogs under development more rapidly when under-exposed. The shorter the exposure to light, the more rapidly will fogging occur."

## New Materials, &c.

Brushes and Pigments for Oil Printing. Sold by James A. Sinclair and Co., 54, Haymarket, London, W.

Mr. James A. Sinclair's firm sends us specimens of brushes and pigments, all of which are of excellent quality. The brushes are the "deer's-foot" form and are issued in a series of sizes. The prices are much the same as those usually paid. No. 10 brush costing 4s., and a No. 5 1s. 9d. Those who study M. Puyo's articles on his practice of the oil process which we published so long ago as August 30 of last year, will not have forgotten the importance there laid upon the usefulness of the brush of deer's-foot or hind's-foot pattern, the rounded surface allowing both large and small areas being treated. M. Puyo, in a later issue of the "B. J." (September 20, 1907), illustrated the form of brush employed by him. Our first supplies were obtained from the same Paris house as M. Puyo's, and though we cannot precisely whether the brushes sold by Mr. Sinclair are of identical origin, it is open for us to state their exact correspondence to those used by the leading French workers. It is, perhaps, too much to say that the articles in the "B. J." of August-September last year constituted the first detailed instruction by French workers to appear in English, and have no doubt contributed to the great advances made here in oil during the past two months.

The pigments supplied by Mr. Sinclair are in nine different colours and are sold in pots at 1s. each. Messrs. Sinclair also supply French inks, "Encre Machine," and "Encre Taille Douce," used by Demachy, Puyo, and others, and our trial of these has gone a long way to convince us that nothing much better can be desired for work in black tones. The black is a purple black, not the objectionable green black that we so often see, and the two inks together give as much variety in the way of softness as can be wanted. "Encre Machine" is a hard tacky ink, apparently soft on the palette, but working very hard on the print. The other is a soft ink, and by mixing the two, or by using the soft ink over the hard, a great variety of effects can be obtained. It is necessary to use both inks, as the one alone is too hard for many prints, just as the other alone is too soft. Our tests show that these French inks are certainly worth trial by every oil printer.

Oil-Printing Papers and Solutions. Made by John J. Griffin and Sons, Kingsway, London, W.C.

Messrs. Griffin have just produced several novelties for oil printing in the shape of special papers and solutions. Their "Pigmoil" paper is a new one, invented by Mr. G. E. H. Rawlins especially for the oil process. It is supplied in two grades, rough and smooth, and can be obtained either in cut sheets or rolls. Up to 10 plates it is packed in twelves, and the whole-plate packet costs 10s. From 10 x 8 upwards packets contain six sheets, a 10 x 8 packet costing 1s. 5d. and a 12 x 10 packet 2s. 2d. The rolls are of any width, and can be obtained in lengths of 6 or 12 ft. at the respective prices of 4s. and 7s. 6d. It is claimed that the paper is far more suited to pigmenting than the older varieties, as it picks up pigment in the shadows and repels it far more vigorously in the high-lights. This is certainly borne out by our trials, for very fine and very brilliant prints even when we started with a very charged brush. A special "Pigmoil" sensitising solution is supplied at 1s. 3d. for an 8-oz. bottle, which makes 16 oz. of solution. According to the printed instructions, this solution is made up from the following formula:—

Potassium bichromate .....	80 gr.
Potassium citrate .....	1 oz.
Citric acid .....	40 gr.
Water .....	10 oz.

The solution sold ready for use is, we understand, twice the strength of this formula, and therefore requires dilution. These "Pigmoil" materials work excellently in our hands, and the only unsatisfactory feature about them is the name. "Pigmoil"! What a word!

For bromoil Messrs. Griffin have now introduced a special

side paper, and also a special one-solution bleaching solution from a formula worked out by Mr. F. J. Mortimer. The paper seems to be an excellent one for the purpose, and the bleacher works well with it. With other bromide papers, however, we were so successful with the bleacher as with the usual ozobromide mixture, though a one-solution formula is certainly convenient. The bromide paper is the same price as ordinary bromide paper, while the one-solution costs 1s. 3d. for a 4-oz. bottle. We prepared our test plates with Messrs. Griffin's amidol "Cartol," which gave a developer that yielded results just suited to bromide work.

"Seltona" Self-toning Boardoids and Postcards. Made by the Leto Photo-Materials Co., Ltd., 3, Rangoon Street, London, E.C.

"Seltona," the very pleasing matt variety of this self-toning paper, has now been issued also as the thicker "boardoid" postcard already familiar to users of other Leto printing papers. It has been too long before the public to require any further praise as a self-toning paper; the agreeable warm brown tone in the ordinary fixing bath is excellent, and the darker red and purple tones obtained by aid of a salt bath are also characteristic of its quality. For the making of prints for reproduction, insertion in slip-in mounts, or for use without any mount at all, the stouter "boardoid" is a most convenient variety. Its quality is further enhanced by the "plate-marking" outfit supplied by the Leto Co., now in an improved form, which includes a Leto mount or folder in which the plate-marked print is inserted. The Leto outfit includes all the necessary materials for this purpose and costs 1s., 1s. 6d., and 2s. 6d. in quarter, 5 x 4, and half-sizes respectively.

"Scaloid" Developer. Made by Johnson and Sons, 23, Cross Street, Finsbury, London, E.C.

Messrs. Johnson, whose "Scaloid" compressed photographic chemicals we have regularly used with every satisfaction, naturally have our interest in introducing a single-solution concentrated developer suitable for all classes of work, and we took an early opportunity of making trial of it. For negative work Azol is added in the proportion of 15 to 30 minims per ounce, the weaker for under-exposures and the stronger for over-exposures. The directions correspond to strengths of from 1 in 32 to 1 in 24, giving solutions which we found useful and effective in practice. The cleanliness of working of the developer is a conspicuous quality; we can imagine nothing better as regards freedom from fogging sensitivities. Azol causes the image to appear quickly, and density builds up steadily, although, as shown by the developing factor, it is not hurriedly. Of the twelve plates, however, which formed the first test of Azol, we secured all necessary vigour, within ten minutes, by pushing development somewhat beyond the entirely correct point. Azol certainly possesses great developing powers, and the solution can be used for a number of plates in succession. The colour of the negatives is a good black without a trace of stain or veil.

Using the developer for lantern slides, bromide and gaslight plates, we followed the instructions and added a little potassium bichromate solution, with which addition the developer works excellently with all three classes of material. The colour of the transparencies and the prints resembles that obtained with amidol more than any other, and the developer no doubt contains an derivative in its composition. At any rate, the concentrated solution supplies an ideal developing solution for all classes of work. All the "latitude" one wants is obtainable simply by the use of bromide and water, whilst the keeping qualities of the solution appear to be indefinite. Azol is supplied in 3-oz. bottles at 1s., and in 8-oz. bottles at 2s. 6d.

THE CAMERA HOUSE JOURNAL," in its current issue, contains a review of Messrs. Butcher's latest introductions, amongst which are mentioned the miniature "Selfix" camera, the Maitland compass gauge, and a pocket ruby lamp, which will doubtless appeal to tourists and holiday makers in general.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, JULY 25.

Southend-on-Sea Photographic Society. Outing to Horndon-on-the-Hill.  
Rugby Photographic Society. Excursion to Warwick. C. L. Oechsner.  
Handsworth Photographic Society. Excursion to Berkswell.  
South Suburban Photographic Society. Excursion to Chislehurst. S. W. Tindley.  
South London Photographic Society. Excursion to Hogsmill River.

MONDAY, JULY 27.

Southampton Camera Club. "Art in Photography." C. Daw.

TUESDAY, JULY 28.

Birmingham Photographic Society. Evening Ramble to Marston Green.

WEDNESDAY, JULY 29.

North Middlesex Photographic Society. Technical Meeting.  
Leeds Camera Club. Excursion to Roundhay Park.  
Bainham Camera Club. "Romantic in Landscape." F. C. Tilney.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, July 14. The honorary Fellowship was awarded to Mr. John Spiller, F.I.C., F.C.S., for his valuable services to the Society as president, vice-president, hon. treasurer, hon. secretary, and member of council during many years, and also for his scientific work. Votes of thanks were also passed to the Rev. F. C. Lambert and Mr. Lindsay Johnson for presents of books for the Society's library.

SHEFFIELD PHOTOGRAPHIC SOCIETY.—The question of the formation of a collection of prints of old views of Sheffield was mentioned by Mr. J. W. Wright at the annual meeting, held at the Builders' Exchange, Cross Burgess Street, last week. Several members of the Society, he knew, had negatives of old parts of Sheffield, and he thought it would be very interesting if prints could be got from those negatives and made into an album either for preservation in the Society or to be given to one of the libraries in the city or to the Art Gallery. The annual report showed that the Society was in a prosperous condition. The number of members at the commencement of the year was 172; resignations, deaths, and lapsed memberships numbered 23; new members elected during the year numbered 55; leaving the present membership 184. There had been 18 meetings held during the year, which had been well attended. In addition to these meetings, a number of practical demonstrations had been given at the Society's work room. The establishing of the work room had been a great success. The fifth Annual Exhibition, held in April, was as successful as the previous exhibitions, the number of exhibits being in excess of those at any previous event. Two classes of exhibits called for special mention—colour photography and the loan collections. Very great interest was shown in the "oil" prints by Mr. C. F. Inston, of Liverpool, and the Council were pleased to know that a number of members had taken up the process. The accounts closed with an adverse balance of £17 13s. 1d., as against an adverse balance of £11 8s. 3d. at the beginning of the year. The officers for the ensuing year were elected as follows:—President, Mr. James W. Wright; vice-presidents, Mr. J. W. Charlesworth, Mr. G. Tomlinson, Mr. J. R. Wigfull; treasurer, Mr. T. G. Hibbert; reporter, Mr. T. W. Jury; lanternist, Mr. W. H. Stubbs; elected members, Mr. J. A. George, Mr. H. Hill, Dr. W. H. Helm, Mr. G. E. E. Noble, Mr. H. S. Nutt, Dr. H. G. Paterson, Mr. G. A. Seed, Mr. T. U. Simonson, Mr. Jonathan Taylor, Mr. F. A. Tinker; Exhibition Committee, Miss F. Ashton, Mrs. J. W. Charlesworth, Mr. J. W. Gallimore, Miss A. E. Jago, Miss E. H. Tillotson, Mr. A. Turner, Mr. G. Walton; delegates to the Yorkshire Photographic Union, Mr. J. W. Charlesworth, Mr. J. W. Wright, Mr. J. R. Wigfull; delegates to the Affiliation Committee of the R.P.S., Mr. G. Tomlinson, Mr. J. W. Wright; hon. secretary, Mr. Henry Merrill, 22, Harboard Road, Woodseats.

EDINBURGH PHOTOGRAPHIC SOCIETY.—The Survey Section of this Society held their annual ramble in Old Edinburgh on Saturday,

July 18, under the leadership of Mr. John Geddie, a well-known authority on old Edinburgh. On this occasion they were joined by members of the newly formed "Old Edinburgh Club." The ramble took the form of a walk round the line of the old walls of Edinburgh. Mr. Geddie gave most interesting lectures at various points on the route. A visit was also paid to Heriot's Hospital. The oak panelling and old paintings on the walls of the council chamber, which has been in use since the building of the "hospital" in 1659, the massive carved stone mantelpieces in the kitchen, and the carved oak pulpit in the chapel, were all much admired, as also was the amount of quaint carving round the quadrangle and on the front of the building. This is one of the finest old buildings in Edinburgh.

## Commercial & Legal Intelligence.

**EASTMAN KODAK COMPANY OF NEW JERSEY.**—In addition to the usual quarterly dividends of 1½ per cent. (being at the rate of 6 per cent. per annum) upon the outstanding Preferred stock, and of 2½ per cent. (being at the rate of 10 per cent. per annum) upon the outstanding Common stock, the directors of the Eastman Kodak Company of New Jersey have declared an extra dividend of 2½ per cent. upon the Common stock, all payable on October 1 to stockholders of record on August 31.

## News and Notes.

**THE OLD-ESTABLISHED BUSINESS** of Mr. Philip H. Fincham, at Myton Road, West Dulwich, has recently been purchased by Mr. Charles F. Dickinson, who, for nearly twenty-five years, occupied the position of Mr. Fincham's chief operator and manager.

**ILFORD PHOTOGRAPHIC SOCIETY.**—Mr. Donald S. Parsons having resigned the secretaryship of the above society, the post is now filled by Mr. T. M. Weaver, of 69, Elgin Road, Seven Kings, Ilford, to whom all communications should be addressed.

**THE LONDON COUNTY COUNCIL** has accepted the tenders of the following firms for the supply of lanterns, lantern accessories, etc., for school use:—R. R. Beard, Butcher and Sons, Ltd., A. Clarkson and Co., John J. Griffin and Sons, Ltd., W. C. Hughes and Co. (London), A. Kershaw, and Reynolds and Branson, Ltd. (Leeds).

**ENGLISH PHOTOGRAPHER'S ARREST.**—In the neighbourhood of Belluno, in the Province of Venezia, a man whose name is given as Richard Rottson, of Liverpool, was found with a camera in his hand in the enceinte of the important fort of Monterico, close to Pieve del Cadore. He was, says the correspondent of the *Telegraph*, arrested and taken to Pieve del Cadore. On examination, none of his plates, which were immediately developed, were found to contain any pictures of importance relating to the fortress. However, Rottson was denounced to the Public Prosecutor, and the Ministries of the Interior and of War were notified of the fact. Rottson states that he was in the vicinity of the fort merely by accident, and that he only wanted to take pictures of the landscape, which in the Cadore district is very beautiful.

**THE PROFESSIONAL PHOTOGRAPHERS** of Winnipeg, Manitoba, Canada, have organised a society under the name of the Manitoba Professional Photographers' Association. The following officers were elected:—President, W. W. Robson; first vice-president, H. H. Bryant; second vice-president, A. B. Spence; secretary, A. L. Lees; treasurer, C. R. Lundy. These, together with A. E. Gentzel and J. W. Gibson, form the executive committee.

**WINDOW TRANSPARENCIES.**—Dr J. Bartlett, in a recent article in the "Bulletin of Photography," recommends the revival of the making of enlarged transparencies for window decoration. Such decorative forms of a photograph are rarely attempted by the hurried

amateur of the present day, who probably has never seen the magnificent results obtainable in transparencies, such as those made by Henry Stevens. Dr. Bartlett suggests the production of a transparency which is opalescent, this result being obtained by adopting the following process after thoroughly removing the hypo of the finished bath. The positive is placed in a bath constituted as follows:—

Iodide of iron .....	1 dram.
Water .....	16 ounces.
Iodine (alcoholic tinct.) .....	6-8 drops.

This gives an opalescent effect, and the image is of a beautiful rose tint. Such transparencies hardly need a ground glass to them off. Hardening in formaldehyde and a coat of varnish is sufficient.

THE "NEW YORK TIMES," Sunday edition, of June 28, reproduced one of the largest and most remarkable flashlight photographs made. It is a view of the interior of the Colosseum at Chicago, the recent Republican Convention in session. So distinct in details was the large photograph taken by the "Times" representatives, and so clear is the reproduction, that over 500 faces in the galleries, and the officers on the platform. It is worth serving as a useful memento of an historical event. The photograph was taken by flashlight, and six men worked twenty-four hours in the preparations. Forty-five bags of powder, suspended from rafters of the hall on heavy cables, were exploded simultaneously at the moment of the exposure of the plate.

## Correspondence.

- \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- \* We do not undertake responsibility for the opinions expressed by our correspondents.

### UNFRAMED PRINTS FOR EXHIBITIONS.

To the Editors.

Gentlemen,—I beg to lay the following proposition before the secretaries of provincial photographic exhibitions. Perhaps they (or their committees) will consider this letter as addressed to themselves in which case it may be of interest to hear their views on the matter. "That any competitor at photographic exhibitions may be permitted to send in prints mounted only."

The reasons against compulsory framing are:—

(a) Damage to frames and glass, especially passe-partout travelling.

(b) Cost of framing and glazing.

(c) Cost of carriage to and from exhibition.

The arguments for (optional) mounting only are:—

(a) Facility in packing and posting.

(b) Saving in cost, both of carriage and framing.

(c) Concusive, therefore, of larger entries and more fees.

(d) The occupying of less wall space.

I am, gentlemen, faithfully yours,

Arkleby, St. Ives, Cornwall.

SYDNEY H. CA

[We fear our correspondent overlooks the vital obstacle to his position, namely, that most photographic bodies holding exhibitions are not so well off as to be able to afford to frame the photographs selected for exhibition. A large proportion of exhibitions are organised for profit, though not infrequently the result is the reverse. Very frequently, too, the time between selection and opening does not permit of any large number of exhibits being framed. It is custom now to frame the pictures sent by foreign exhibitors, and appears to us to be as much as can usefully be done. Apparently our correspondent thinks that prints both framed and unframed might be used together in an exhibition, a proposition which surely not necessary to discuss. Some other points suggested perhaps be best left for our readers' comments.—EDS. "B.J."]

## Answers to Correspondents.

Matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered in the names and addresses of the writers are given.

Communications relating to Advertisements and general business matters should be addressed to MESSRS. HENRY GREENWOOD & CO., Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street Strand, W.C., make the registration of copyright photographs at a charge of 2d. each photograph, to cover cost of registration fee, form, etc. Unmounted copies of each photograph must be sent with the

### PHOTOGRAPHS REGISTERED:—

14, High Street, Glossop, Derbyshire. Two Photographs of "General" at Talbot House, Glossop.

Thompson & Co., Rose Inn Street, Kilkenny, Ireland. Photograph of Mr. J. All Ireland Hurling Champions.

"Mead Cliff," Meadfoot Lane, Torquay. Photograph of Mr. F. J. J. Driving from Saddle Rock, Torquay.

Hard, 121, Oldham Road, Ashton-under-Lyne. Three Photographs of Whitehead of the Lancashire County Cricket Team.

27, Church Street, Preston, Lancs. Photograph of New St eet, Preston.

Shmore, 11, Brand Street, Hitchin, Herts. Photograph of "General" and Sir John Gort at Letchworth.

FOR INVENTION.—Will you advise me how to protect an invention for a short period, so I can offer it for sale, and what cost, etc.?—A. E. READ.

cost will be £1. Apply to the Comptroller, Patent Office, Compton Buildings, London, E.C., for the printed form of application.

STUDIO.—I saw mentioned in your JOURNAL some special treatment or putty for keeping out the wet and used on studio. Was the name "Carson," and can you furnish me with address? I am sorry I did not keep the cutting for future use. Can you the trouble of replying.—CARELESS.

Carson and Sons, Grove Works, Battersea, S.W.

GLASS.—Impossible for us to say. Try on one or two scraps of glass.

—Mawson and Swan, Mosley Street, Newcastle-on-Tyne. Give a list of the most useful and permanent colours in the market, page 837.

—May I ask a question as under? Last April I was employed by a travelling photographer as operator, retoucher, etc., and came over from Ireland to this place. After being with him for several weeks, a letter was placed in my hands by himself stating that I did not require my services any longer, giving no cause as reason in dismissing me. In the first instance he engaged me on telling it was a permanency, and hoping I should accept of it. When he told me it was not a fair dismissal (as when he paid me nothing, nothing was said), he thereupon told me if I was dismissed by his dismissal I had better give him mine, which I did not. Although it is two months since I had to go, should be glad if you will tell me if I could, upon suing him, win the day, as I have no money to do so and would rather take my chances than lose everything.—J. B. D.

—If you were paid a weekly salary you are entitled to a week's salary (not more), or a week's salary in lieu of the notice. It is not of no use your suing for more than that. The fact is your employer said the engagement was for a permanency nothing; an agreement to that effect should have been in the contract to be of any value.

B. SOLUTION.—Will C.C. toned with the above, as in page 492 ("B. J.," 26th ult.), be as permanent as if gold and platinum?—OLD KROW.

—The opinion is that the prints should be fully as permanent.

POSTCARDS.—Can you tell me if there is anything on the market with which I could do the titling of postcards (which must be sensitive)? I remember seeing some years ago a small holder

into which the type was screwed to make a person's name; it is something of this sort I want. If you can give me an address of where I am likely to obtain this I shall be much obliged. 2. Also do ferrotype plates require any coating before placing postcards on same, and would they require any special polishing after using a few times?—POSTCARDS.

1. Appliances for the purpose are sold by Richford and Co., 8 and 9, Snow Hill, E.C.; O. Sichel and Co., 52, Bunhill Row, London, E.C.; and W. Butcher and Sons, Camera House, St. Bride Street, E.C. Another method, which we have frequently given in this column, is that on page 807 of the "Almanac." 2. Usually no treatment is necessary. If any, a little solution of spermaceti wax 20 gr. in benzole 1 oz., may be rubbed on the plates with a piece of flannel, and the glass afterwards polished with silk rag or chamois leather.

LUMINOUS PAINT.—Would you kindly inform me where I can procure Balmain's water-process luminous paint?—EXPERIMENTUS.

John J. Griffin and Sons, Ltd., Kingsway, London, W.

THIN NEGATIVES.—I use a single-solution developer, made up with metol 2 drms., hydroquinone 3 drms., metabisulphite 1 oz., carbonate of soda 6 oz., water 80 oz. Unfortunately my assistant put in 6 oz. of soda sulphite instead of 6 oz. carbonate of soda, and a batch of plates were placed in developer before this was known. After being in developer for five minutes (usual time for being developed in), they were taken out and found to be very thin, and more like positives, although detail was clearly shown. They would not develop up further, and are quite useless for printing. Is it possible to "blacken" the negatives in any way? I cannot get another sitting.—PERPLEXED.

The best thing you can do is to intensify with the uranium formula as given on page 802 of the "Almanac." We would have answered this query in last week's "Journal" had it been addressed to the Editors. Queries which arrive on Wednesday morning, not marked "Editorial," reach us too late for reply in the Friday's issue owing to the large number of small advertisements received by the same post.

H. H.—There is no reliable list published.

RETOUCHING (H. L. B.).—Your retouching is very fair, the restraint shown in working the study of old lady being its best feature, although some of the deeper lines on lower half of face are unduly removed. The work on print marked No. 2 is very good and natural, the likeness is preserved and the grain not overdone. No. 1 shows a wrongly directed touch, especially on the cheeks—the effect is vertical. The lady in group is rather ragged edged, and No. 3 shows the retouching too plainly. Conceal your technique more with softer blending and fewer lifts of the lead.

METABISULPHITE.—In the letter by Mr. B. J. Edwards in the "B.J." for February 15, 1907, page 129, on making up pyro and soda, he says: "For the pyro solution the metabisulphite of soda in crystals (not powder)," etc., etc. Will you tell me what is the difference between the crystals and powder? I have tried to get the former in this town without success, and am told there is no difference, and one chemist told me he had never heard of crystals.—OLD KROW.

The crystalline form is a mark of purity, and, further, powder which has been in stock for any length of time has most probably deteriorated owing to its finer state of division. We advise you to get the crystal metabisulphite of potash (which is just as suitable as that of soda) from Messrs. Mawson and Swan, Newcastle-on-Tyne.

OVERNETH'S LIGHTKUPFERDRUCK.—Can you greatly oblige me by telling me how I could find out working formulae, etc., of Overnether's process of etching copper, in which the positive film of a transparency is stripped, converted to a chloride, put into contact with a copper plate, and the action hastened by electricity?—E. C. W.

The method, which was called "kupferlichtdruck," consisted in making a negative in chloride emulsion direct on the copper. At the time of Overnether's death in 1887 it was a secret. Etching copper by electricity was patented by Sir Joseph Wilson Swan, but we believe the process was never actually carried out. On the face of it this Overnether process seems to be a process for making photogravure, and on the information given we cannot see that there is any advantage over the common Talbot-Klic method.

**RETOUCHING** (reply to "A. S.")—You must send us better prints if you wish us to criticise your work; these are absolutely useless for the purpose. Make them on glossy P.O.P. to good, level strength to show the detail of the retouching. Tone and fix the lot, writing on the back of each print the time taken to retouch. You should submit studies of a child, a young man or woman, and an aged face of either sex, showing wrinkles and character marks for preference.

**T. J. GOBBETT**.—If you will say what dyes you are using at present we will try and answer your query next week.

**H. E. SIMPSON**.—There is no publication which contains more information on the subject. We may refer you to the "Colour Photography" Supplements which appear with the first issue in each month of the "B.J."

**EMPLOYERS' LIABILITY ACT**.—I employ several canvassers (house-to-house), on commission only. Should anything occur in the shape of an accident while at work am I liable under the Workmen's Compensation Act, or are they simply agents, working on their own behalf, not receiving any salary?—**INSURANCE**.

This is a query we cannot answer definitely. The Employers' Liability Act contains many knotty points, and, so far as we are aware, the question you put has not as yet been raised in any Court of Law. Until it is, the question is an open one.

**YELLOWED PRINTS**.—I shall feel indebted to you if you can tell me the cause of so many of my prints going yellow, or after a time—a short time—showing yellow patches, like the samples sent herewith. At first I thought it was because they were not washed sufficiently, but now I feel sure that is not the reason, for I now wash them thoroughly in a dozen, or more more, changes of water, and then leave them in dribbling water all night. Still they seem to turn out as before. Quite recently I have had a lot returned by customers and I have had to replace them.—**COUNTY PHOTO**.

We may tell you at once that the long soaking that you have recently been giving the prints has really added to the evil rather than otherwise: The actual cause of the trouble is that the prints are not completely fixed—that is, the silver salts have not been converted by the hyposulphite of soda into the soluble state, so that they can be removed by water. That is evidenced by examining the prints by transmitted light. The remedy is to allow a longer time in the fixing bath, and have a stronger solution than you say you employ.

**SILVER SAVING**.—We have read in one of the old volumes of the JOURNAL that a considerable quantity of silver is contained in the used developing solution, and that workers should be careful to save it. Since reading this we have been careful to save all our old developing solution and it has now accumulated to a large quantity. We shall be obliged if you will tell us the simplest way to recover the silver from it?—**BAD TIMES**.

We are sorry to tell you that you have had all your trouble for nothing. What you read applied to the developer used for plates in the wet collodion process. That was always rich in silver after use; indeed, if it was allowed to stand for a short time, metallic silver was deposited in it without any further treatment. The alkaline developer, from gelatine plates, contains no silver, and is therefore worthless. Gelatine plates contain no free nitrates of silver, whereas collodion ones contain a good amount of it, which is reduced to the metallic state in the development.

**SITTERS' RIGHTS**.—A couple of years ago we took the portrait of a lady customer, at that time not a person of note. Since then she has gained some notoriety, and her portrait, the one taken by us, appeared in an illustrated paper a fortnight ago, but without our name under it. We wrote to the publishers of the paper, asking them to remit the usual fee for the reproduction. The reply we got was to the effect that the lady supplied them with the portrait and that they would not pay us anything. What can we do to recover a fee, and how much should we demand, seeing that our permission was not asked?—**WILTS**.

You can, of course, do nothing, as you are in no way entitled to any fees. The lady paid you for taking her portrait, and she has the right of doing what she likes with it.

**VELOX**.—The bright sparkling points in the print sent are due to air bells imprisoned between the print and the ferrotype plate on squeegeeing. Possibly there was only one air bubble when the print was laid on the plate, but that was broken up into innumerable

small ones in the squeegeeing. More care in the future will avoid this in the future.

**Y. Z.**—If the agreement is not stamped it is of no value, a late employee can start business just where he likes and cannot prevent him.

**H. J. BIRD**.—The general design of the studio is good, and well be improved upon; but it is a little too short for professional work—groups and full lengths. We should not its being four or five feet longer, if that is possible. Systems of blinds are good, but the horizontal system, in case, is the preferable. The material and colour enclosing your letter are good for both sets.

**S. AND COMPANY**.—The copyright is unquestionably yours; you did not register it you can recover no damages for its infringement. All you can do now is to register the copyright, prevent the further sale of the piracies. You can receive for what was done prior to the registration. But if there are, as you say, having a large sale, the publishers may wish to come to terms with you for the continuation of it.

**A. C. H.**—Better write to the makers of the paper, send examples of your troubles. They will be better able to cause of them than we are from your mere description, and the way, is very vague.

**ATAK**.—The patent about which you inquire, we find, is beyond the provisional stage, consequently the details of the process have not been published. Formerly the provisions of the patent were not completed, and the provisions published, now they are not, they remain as the inventor's.

**J. E. WARD**.—From the description, we know the apparatus is Johnson's pantoscopic camera, for taking panoramic on flat plates. It is evidently out of repair, and cannot be repaired.

**OPERATOR**.—There is no fixed rule as regards holidays in studios. Some give a fortnight, some few more, and some, indeed, none at all. Very generally no holiday is given to those who have not been in the employ for at least a year. You have only been in your present berth six months, and you are surprised that you are not to have a holiday, and that you have one in your last place of course makes no difference to your present employer.

**G. H. CREASY**.—Hunt's Book, "Researches on Light," has been in print for many years. It is possible that you might secure by means of an advertisement in our columns. The book is now, and we expect you, if you get it, will have to pay for it beyond its published price. Try Mr. Tregaskis, High Holborn.

**J. O. JONES**.—The Petzval portrait lens is by no means a bad lens for copying purposes, and we are not at all surprised at your enclosing, considering the focal length of the instrument. The best lens for copying purposes is one of the modern anastigmat and next those, a R.R., or the old form of triplet, which means a bad copying lens.

**NOVICE**.—It is not safe to use the fixing bath for more than a batch of prints, and certainly it should not be used for days in succession. Hypo is cheap enough now, so that you need not enter into consideration if the stability of the prints at the moment.

**\* \* NOTICE TO ADVERTISERS**.—Blocks and copy are received for the approval of the Publishers, and advertisements are accepted absolutely without condition, expressed or implied, as to what is the text portion of the paper.

## The British Journal of Photography

The Oldest Photographic Journal in the World.

ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWO

### TERMS OF SUBSCRIPTION, Post

(UNITED KINGDOM AND THE CHANNEL ISLES).

One Year ... 10s. 10d. Half Year ... 5s. 5d.

# What professional photographers say of **HOUGHTONS'** **ARTISTA** PAPER

ANY OF THE ORIGINAL LETTERS CAN BE SEEN ON APPLICATION AT OUR NEW  
SHOWROOMS FOR PROFESSIONAL PHOTOGRAPHERS AT HIGH HOLBORN.

Nothing like it.

"I have come to the conclusion that there is nothing else  
on the market that can approach it, let alone imitate it."

Beautiful.

"I must say it is a beautiful paper."

Grand paper.

"Have no hesitation in saying that it is a grand paper, and  
is the printing process I have been looking for ever since  
I knew what a print should be. I am delighted with  
all the points of it."

Splendid.

"The paper is splendid; the best I ever handled."

Quite distinct.

"I am very pleased with Artista Paper and consider it to  
be a fine printing medium quite distinct from all  
existing papers on the market."

Extremely pleased.

"My customers are extremely pleased with photographs  
on this paper."

Giving great satisfaction.

"I may inform you that Artista Paper is giving great  
satisfaction to my customers."

IF YOU WANT TO PLEASE **YOUR** CUSTOMERS AND REVIVE TRADE BY INTRODUCING  
A STYLE OF PICTURE THAT IS DIFFERENT IN APPEARANCE AND SUPERIOR IN QUALITY  
TO ANYTHING THEY HAVE SEEN BEFORE, WRITE TO HOUGHTONS' PROFESSIONAL  
DEPARTMENT, AT 88/89, HIGH HOLBORN, FOR A SAMPLE OF **ARTISTA** PAPER.

Please mention the "B.J." when  
corresponding with advertisers.

# MARION'S GREAT CASH PRIZE COMPETITION

## JUDGES:

Class 1.—F. J. MORTIMER, Esq., F.R.P.S.,  
*Editor of "Amateur Photographer" and "Photographic News."*

Classes 2 and 3.—R. CHILD BAYLEY, Esq.,  
*Editor of "Photography and Focus."*

Class 4.—CHAPMAN JONES, Esq., F.I.C., F.C.S.

(The Competition will be divided into Four Sections.)

### 1—OPEN CLASS.

Open to everyone, without restriction as to subject, except that the photograph shall be of pictorial character.

PRIZES.....

£50, = £20,  
£10 and £5.

### 2—BEGINNERS' CLASS:

As the first class, except that it is only open to those who have not hitherto received an award.

PRIZES.....

£15, = £10,  
and £3.

### 3—MOVING OBJECTS CLASS:

The object or objects photographed must show evidence of moving.

PRIZES.....

Soho Reflex Camera complete  
with Goerz Syntor Lens,  
£5 and £2.

### 4—SCIENTIFIC CLASS:

For Photographs of Scientific interest.

PRIZES.....

£10, = £5,  
and £2.

THIRTY OTHER PRIZES are offered in addition to the above, namely, 15 of ONE GUINEA each, and 15 of HALF-A-GUINEA each, and these will be divided among all four classes according to the number of entries and merit in each case.

## SUMMARY.

essor Namias has recommended a bath of nitric acid after a negative in the mercury and ammonia intensification pro- the added treatment prevents the yellow veil which appears sure of such intensified negatives to light. (P. 580.)

further practical points on the making of diagram lantern e given on page 578. It is pointed out that without obtain- alation, advantage can be taken of the spreading action in the film to obtain lines of greater thickness.

oncluding portion of Mr. Harold Baker's article on photo- will be found on page 583.

ent paper before an American Convention discusses the evil the coupon system in professional photography. (P. 580.)

note a recent appreciation of the child portraiture of Mr. from "The Quiver." (P. 581.)

s for colour screen-plates, colouring photographs, three- rojection, and a tripod head were published last week.

s of a photo-lithographic process recently patented by a rker appears on page 587.

orsley Hinton Memorial Fund now stands at a total of £520. (P. 586.)

pers and list of successful candidates in the recent cine- h operators' examination have been published. (P. 587.)

ra and benzole. Recommendations as to the proper use of ra have been made by an American chemist, and this would save much confusion in photographic formulae.

## EX CATHEDRA.

### Employers' Liability.

The disquieting features of the present Act for the compensation of employees were further confirmed last week by the judgment in the Court of Appeal, which upheld the previous decision of a County Court judge that a washerwoman who comes in to work on certain days is a "workman" within the meaning of the Act. The Court affirmed that such employment was "periodical" as distinguished from "casual," and that therefore in the particular instance the "employer" was liable for the injury sustained by his washerwoman by pricking her thumb with a pin whilst washing the cellar steps on one of the alternate Tuesdays on which she was in the habit of attending. Although framed in the interests of the employees we are afraid that the Act must largely affect this very class prejudicially. It must tend to induce employers to dispense whenever possible with services which expose them to liabilities such as the foregoing. They will be less ready to call in outside assistance for their staffs. The outsiders thus lose their employment, and the regular servants have to perform duties of which formerly they were relieved.

\* \* \*

### Photographic Fallacies.

In a recent article in our columns on "Photographic Fallacies," Mr. A. Lockett referred to the well-known one that the  $f$  number of a stop represents the number obtained by dividing the diameter of the stop into the focal length, and he remarked that this idea still lives and thrives, though the fallacy has been pointed out with monotonous frequency. In the same week that his article appeared we read the following in a contemporary:—"The  $f$  number (near enough for all practical purposes) may be ascertained by dividing the distance which the ground glass is from the stop when the lens, or half lens as the case may be, is focussed for infinity, by the diameter of the stop itself." This lucid paragraph not only lends authority to the fallacy quoted by Mr. Lockett, but introduces another, viz., that in a half lens—which we may safely assume to mean the half of a doublet—the focal length is measured from the stop. The information is, therefore, incorrect for either a doublet or half a doublet, the error in the latter case being a very considerable one. The difficulty of correcting photographic fallacies is by no means lessened when journals devoted to photography assist in perpetuating them, and even help to introduce new ones.

\* \* \*

### Technique.

We see in the "Photographic Journal" that in the discussion that took place on Mr. Horace Mummery's paper on "The Artistic Impulse," much was said about "technique." Some speakers seem to think

that we have too much of it, and others that we consider it too little, but none defined it. Their allusions to it were all delightfully vague, but repeated readings of the discussion leave us with the impression that all had different ideas as to what technique is, or what it should be. The President suggested that the word has a different meaning in photography from that which it has in painting; but it appears to us that photographers would be best advised to leave the word alone, and not worry about its meaning. In painting it is clear enough, but in photography it is even doubtful if the word is applicable—excepting, perhaps, in the case of oil printing—and its frequent use only suggests a meaningless catchword or shibboleth. At present it is used by photographers in much the same vague, non-comprehending fashion as the word "breadth," and the result is that no one can understand either. Wise people are deaf when art talk degenerates into catchwords, therefore the talkers waste their time.

\* \* \*

**Photograph v. Sketch.** An interesting example of the relative value of photographs and of sketches is to be found in Piazzi Smyth's book, "Teneriffe, an Astronomer's Experiment," published in 1858. The author was the first to produce a book illustrated with stereoscopic photographs, and he was greatly impressed with the value of photography for record purposes. One of his illustrations is of the Great Dragon tree of Orotava. This tree is described as being about 60ft. high, and its appearance, as seen in the photograph, is hardly that of a tree at all. Indeed, the author calls it "merely a vegetable: an asparagus stalk with a remarkable power of vitality, and an equally eminent slowness of growth," its growth being so slow that it had the credit of being the oldest tree in the world. There is, however, an illustration of this tree, by Prof. McGillivray, of Aberdeen, in which it is represented as a "huge elm tree, with a superabundance of small leafed foliage, a height of 150 ft., as measured by the man going up the ladder, and the position solitary, in a nearly level country." The absurdity of the illustration induced Prof. Piazzi Smyth to trace its history. McGillivray had copied Humboldt, so that authority's drawing was looked up and found to represent a sycamore about 95ft. high. Humboldt, however, had copied from a drawing by a M. Marchais, and he again from a sketch by a M. Ozone. Piazzi Smyth therefore applied to the hydrographical department of France, and was supplied with a certified copy of the original sketch preserved among Ozone's papers. This showed a tree of the right height, and, though it had too much foliage, still it was possible to look upon it as a rough hurried sketch from nature. This first sketch was not good, but successive copyists had in time produced nothing but a caricature of the idiosyncrasies of the first artist, who had only drawn what he thought he saw, including a non-existent ladder. Precisely similar errors have been perpetuated in many of our text-books, especially the natural history books, which give illustrations of beasts and birds that never yet existed. Since Piazzi Smyth's time photography has done a good deal to correct these errors, but there is still much more to do.

\* \* \*

#### Early Photographs of the Solar Spectrum.

Another interesting passage in Prof. Piazzi Smyth's book relates his experiences in photographing the solar spectrum. He was not provided with the modern "spectrograph" or any instrument approaching it, but simply built a hut or "optical room" with stones, planks, and canvas, and put a slit in the wall. His heliostat was a man with a mirror outside the slit, and he himself worked inside the room, at first making draw-

ings only of the Fraunhofer lines. This was so tedious continued day after day, and repeated several times day, that he tried to photograph the lines, but found no amount of exposure with his collodion plates to bring on anything but a faint coloration in the region. After many failures he tried the effect of a quartz train lent by Prof. Stokes, and "instantly photographic action was most intense." He tried exposures of one minute, of ten seconds, five seconds one second, and still the plates were solarised. He contrived a device to give an exposure of a tenth second, and produced fine results. As he says, "we were mapped down with more certainty in that short than in days by eye and pencil." If not the first photographs of the Fraunhofer lines these must have been early ones, and it would be interesting to know if plates are still in existence.

\* \* \*

#### Casein Carbon Printing.

In our "Patent News" column July 17 we published the specification of a patent for a new process of pigment printing which is claimed to be an improvement on the present carbon methods, in which the chromo salts are employed. Casein takes the place of gelatin, and in place of the bichromates of potash or ammonium ferric ammonio citrate, sulphate of cerium, or a uranyl salt, is used. It may be mentioned that there is no novelty in such an application of casein, neither is that of the ferric ammonio citrate, which is the sensitisising agent in most of the iron processes. There is, however, a novelty in the use of the cerium, or uranium, salt in conjunction with casein. If this process comes into use it will not be on account of its cheapness, for it will be more costly, as sulphate of cerium costs about the number of shillings per pound as the chromate salt, while uranium is very much dearer. Further development, whilst in the ordinary carbon process only is required. It is, however, claimed that paper prepared according to this patent is more sensitive, and keeps longer, after sensitising, than does that sensitised with bichromate. In case any of our readers may like to try the process, we give the formulæ as given in the specification:—5 grams of anhydrous casein are dissolved in 75 grams of water containing 2 cc.s of ammonium citrate. 2½ grams of ferric ammonio citrate are added, and the mixture is admixed, and the substance is spread on paper; the ammonio citrate of the compound described above may be replaced by 2 grams of sulphate of cerium and 5 decigrams of tartaric acid, which are dissolved in ammonia water.

#### ON MAKING DIAGRAM LANTERN SLIDE

A WEEK or so ago we referred to the badness of the diagram slide shown at scientific lectures, and suggested one or two of the precautions that are most necessary in making the negative. It is, however, impossible to produce a good negative from a bad diagram, and it is very easy to produce a bad slide from a good negative. Therefore, other matters besides the negative that require consideration.

The diagram naturally comes first, and this should be drawn boldly on good white paper or card with pen and black ink. Its scale should be twice or three times the size of the final slide image, and the lines should be thick, while the lettering must be large and bold. Fine lines, or small thin lettering, add to the difficulty of preparing a good slide, and they are apt to be invisible on the screen. Bold drawing is therefore

and it is a safe rule to draw the lines so that they are a little too thick, and to write the lettering and descriptions so that they look just a little too large. In the final result they will then appear just about right. A great deal of trouble is the ink, which is apt to be glossy, and to reflect a good deal of white light. Laziness induces people to use one or other of the specially prepared drawing inks on the market, but the best way to avoid trouble is to use nothing but pure Indian ink rubbed fresh with water in a proper china palette. This has more glaze than the ready-mixed inks, and if the drawing is made on good quality drawing paper, and when quite dry is washed well under a tap, the little glaze that exists quite disappears. For line diagrams, however, Bristol is the best drawing material, and this will not stand washing. Generally, washing is unnecessary if a good ink is used, and if the five minutes required for rubbing up the ink is objected to, the next best substitute is, perhaps, Indian's ordinary ink, not the waterproof variety. The best arrangement for copying is undoubtedly a vertical one, with the drawing lying flat down on the floor held down by weights or a slab of plate glass, and the camera arranged vertically above it. We work in front of a window, and the exposure is calculated by a Wynne's meter held facing the light half-way between the window and the drawing. One quarter the exposure indicated for copying in use on a normal subject is then just about right for reducing on the scale suggested. There is no difficulty in fitting up a suitable vertical arrangement to any camera accustomed to make-shift methods of working, but if a vertical light is used, a horizontal arrangement is to be preferred. In this case the whole of the apparatus may be placed on a table, and even illumination can be secured either by lamps on either side of the camera, and equidistant from the copy, or by using one lamp and giving half the exposure with the lamp on one side of the camera and the other half with the lamp in a corresponding position on the other side. Exposure must, of course, be determined by trial, as it will depend entirely on the kind of paper used.

Before stated, backed process plates should be used, and they should be developed for from three to four minutes in a hydroquinone and caustic soda developer containing two grains of bromide in every ounce. After the negatives must be cleared in a strong Farmer's reducer, say a mixture of equal parts of 10 per cent. hypo and 10 per cent. ferricyanide solutions. The safest method is to dip the negative into the reducer and then immerse it under a strong stream of water from the tap, continuing the process until the lines look quite clean and free from fog or veil when examined with a magnifier. A more powerful method is to dip a pad of wool in the reducer and wipe the lines with it, and then the plate under the tap after each application. If the lines are badly veiled this is the most effective method, but must be applied with care, otherwise the "whites" will be reduced also.

After washing, the negative should be carefully examined under a strong light, and if the "whites" appear quite clean it can be dried. If not opaque, intensification is required, but it is not necessary to use such powerful intensifiers as the lead intensifier usually recommended if the lines have been given are carefully followed. The potassium intensifier or mercury and ammonia are quite sufficient. After intensification and washing, the negative should be again applied to clear the slight veil which almost certainly come back over the lines, and a final wash the plate can be set up to dry.

Before printing, the dried negatives should always be laid by laying them face down on a sheet of quite white paper when the lines should show up quite clearly. If

they do not, then further reduction is required. The density of the whites should also be again tested, and it is worth while to intensify any negative that has even a suspicion of thinness, for by ensuring that all the negatives are perfect, the slide-making is reduced to an automatic proceeding. Spotting is always required, and it is very easily effected with photopake.

Next comes printing, and here again only backed lantern plates should be used. With Imperial plates the average exposure is from 10 to 15 seconds at a distance of 6 ft. from an incandescent burner inside an opal globe. Such a burner, with a byepass, is of the greatest convenience in work such as this. Development is conducted with the same developer as that used for the negatives, and will take from two to three minutes. It should be stopped the moment a slight veil appears over the slide. After fixing, the veil is cleared by a momentary dip in a very weak Farmer's reducer, say 10 per cent. hypo solution just tinted yellow with ferricyanide. The final result should then show sharp black lines on a clear glass ground, and any slide that is not quite perfect in this respect is best replaced by a new one.

Imperfections are best detected by laying the dry slide film down on white paper. If the result is a perfectly black sharp image on a white ground the slide can be passed as perfect without a test in the lantern. It need hardly be said that the slides should be varnished. Celluloid varnish is the best to use, and two minutes on a whirler will render the varnish quite hard. Of course, the slide should be heated to ensure that it is dry before varnishing. If any dust falls on the varnish it can easily be removed with a brush dipped in the varnish, and a second coat of varnish will then remove all signs of brush marks. The rest of the work needs no special comment, excepting that masking is greatly facilitated if a wide black border line is put on each diagram. It is then easy to mask up to this line with strips of paper, and good masking adds much to the appearance of the slide.

Uniformity of result is vitiated by using the developer for too many plates. A good rule is to use 1 oz. to each quarter-plate when making the negatives. That is to say, 2 oz. of developer can be used for two plates in succession. In making the positives the developer will go farther, as the time can be controlled by inspection. Two ounces can be used for four slides in succession with perfect safety, but it is unsafe to go beyond five or six slides.

It is worthy of note that the thickness of the lines on the slide depend a good deal on the exposure. Over-exposure gives an halated line, but before halation appears the line grows rapidly in thickness while remaining quite sharp. A very thick line negative will therefore stand a short exposure in printing, while a fine line negative will give the best result with a longer exposure—say, half as long again. In the conditions we described, 15 seconds will be about right for a thin line and 10 for a thick one. This effect of exposure on the thickness of the line is somewhat curious, and very interesting results can be obtained by making a series of graduated exposures.

---

AN ALBUM OF BUSCH PHOTOGRAPHS.—The Emil Busch Optical Co., 35, Charles Street, Hatton Garden, E.C., have issued a small album containing photographs taken with "Busch" lenses. The pictures are of sufficient merit to interest the many callers who frequent the dealer's premises for the purchase of their photographic supplies, and it is the company's desire and intention that the album, to which are attached their catalogues of lenses, cameras, and accessories, should have a permanent place on the counter, for the perusal of the dealer and his customers. Dealers are requested to write Messrs. Busch for the album.

## ON THE USE OF NITRIC ACID AS A CLEARING BATH IN INTENSIFICATION WITH MERCURY.

[In this article, which Professor R. Namias contributes to "La Photographie des Couleurs," the use of a 1 per cent. bath of nitric acid for ten minutes is advanced as a means of avoiding the general slight veil produced in mercury intensification. The bath is used before the application of the ammonia or soda sulphite solution.]

It is often noticed that negatives intensified with bichloride of mercury become stained after a time and covered with a general fog or veil which greatly obstructs printing. I have found the same defect to be present, although to a less degree, in negatives treated with bichloride of mercury and darkened with sulphite instead of ammonia. The same drawbacks have been experienced by many amateurs, from whom requests for assistance in the matter have frequently come. I have always attributed part of this failure with the intensifier to the imperfect washing out of the excess of bichloride, which substance in the ammonia bath is converted into the white, insoluble mercuric chloramide. But this cannot be the cause when sulphite is used as the blackening agent, and in fact I have noticed in the course of experiments with the mercury compounds that sulphite of soda acts as a solvent of the majority of mercuric compounds (even of the insoluble compounds) but not of the mercurous compounds. I have, therefore, undertaken a series of experiments in order to discover the cause of this difficulty in the process, and to prescribe a remedy. For this purpose a number of gelatino-bromide plates were first fixed in hyposulphite of soda and washed for twenty-four hours in running water. They were then treated in the following separate ways:—

1. Immersion in mercuric chloride solution containing 2 per cent. common salt, followed by careful washing and subsequent darkening in a bath of ammonia.
2. Treatment as in 1, but adding to the mercury solution not only 2 per cent. of salt, but 1 per cent. hydrochloric acid.
3. Treatment as in 2, but giving the plate, after immersion in the mercury bath, ten minutes in a 1 per cent. solution of nitric acid, afterwards washing carefully before immersion in the ammonia bath.
- 4, 5, and 6. The plate was treated as in 1, 2, and 3 respectively, but a solution of 5 per cent. soda sulphite was used in place of ammonia.

The plates thus obtained were examined by transmitted light, and half of each then covered with a piece of black card and

exposed to light for twelve consecutive hours, for three of bright sunshine fell on them; whilst for the rest of the time they were in bright diffused light.

At the end of this exposure they were again examined by transmitted light, when the following conclusions were reached:

1. Plates treated with bichloride of mercury in neutral solution, and carefully washed for a long time, do not lose of their transparency at the time, but on exposure to light become covered with a general yellow veil which increases the exposure to light. This veil appreciably clouds the image, and, moreover, is not uniform, but varies enough in density in different parts of the plate to produce a print of uneven vigour.

2. Plates treated with a neutral or acid solution of bichloride of mercury and placed, after washing, in a solution of soda sulphite, immediately become clouded with a slight general veil, which becomes a little more appreciable when the negative is exposed to light. But even in this case the coloration is always uniform over the plate.

3. Treatment with nitric acid in 1 per cent. solution, for sufficient time prior to the bath of ammonia or sulphite, invariably resulted in the avoidance of the veil, which form at the time nor on subsequent exposure to light, the negative, say, to any appreciable extent.

The action of the nitric acid is probably based on the removal of the traces of mercury salt which washing alone does not remove from the gelatine film. Apparently this small quantity of mercury is not affected by ammonia, but it is nevertheless sensitive to the action of light. In the case of sulphite these traces of mercury salt are immediately reduced, and thus cause the immediate veil produced by this bath.

The use of the nitric acid solution should completely prevent the formation of an impermanent image in mercury intensification, and should be of particular service to professional photographers who have occasion to do much printing from an intensified negative.

R. NAMIAS.

## AN AMERICAN VIEW OF THE COUPON SYSTEM.

[Papers read before the conventions in America take, as we have often pointed out, a pronounced business tone. The American professional is easily induced to gather with his fellows, enjoy himself, and talk business in the frankest manner. In several recent papers on business topics, the following, read before the Association of the Pacific North-West, deals with a dangerous element in the present-day photographic business, and prescribes the remedy which has been often prescribed in vain.—Eds. "B.J."]

I know that many men say that in business all have an equal right to adopt any price for their products, and any system of inducing trade they may choose, and it sounds as though that were true, and it is true if there is no regard for the elevation of our chosen art, or if you only desire to get all the ready cash out of the public possible, in the least possible time, and then quit the business. I refer to the coupon system of inducing trade. I am informed that there are two classes of coupon vendors: one who tries to redeem his promises to the public, and really gives them all he advertises to give, and another class who make no pretensions of keeping faith with the public by giving what they claim to give, but simply aim to get the customer into their place of business, and then apply the graft methods to the limit. Regarding the latter class, I have no

language suitable to express my contempt for their method of doing business. I cannot call him a photographer, rather, a faker. The former class mentioned are honest, I think, very thoughtless as to the fact that they, by putting their hands deep into the pockets of all photographers who adopt a standard price for their work and endeavor to make good by doing better work from day to day. I can plainly why I say this. Suppose, for illustration, Mr. Smith established himself in business in a certain town, and has a fair price for his photographs—a price that is generally conceded by the craft at large as being a fair living price. He works along quietly and honestly, giving his best efforts and endeavoring to improve his work, and enjoys the confidence of the public. As time goes on the public becomes educated to the price

photographs, until they consider it a standard of value. It may be other photographers in the same town who do not get so much for their products as Smith does, but perhaps they do not quite as good work, and their pictures are not so much. Mr. Smith gets the best trade, as we say, and attracts a less critical class of customers. Now, along comes the coupon man, and he says, "I will give my regular ten-dollar set of photographs for \$1.99 per dozen." Why does the public ever itself to rush to him to be grafted? Possibly, or granting that they do get two free pictures, they certainly do not get a work of art. It is plain that the reason they prefer it such a great chance is simply because Smith has established a standard of value, and the public thinks to get the same value for a small fraction of Smith's price. It seems that it does not require any great amount of reasoning to conclude that the public would not have made this sudden rush for the coupon man had it not been for the fact that Smith was up a living price, and Mr. Coupon Man reaps the benefit of years of effort to establish that price.

Suppose Smith, and all others in the business in that town, to adopt the same price and methods as the coupon man—would they be any rush to either, greater than to the others, granting that their work was equal in quality? I think not. Would they continue a rush very long? I think not. Would either of them? I certainly doubt it. Well, Smith does not lower his price, nor surrender the dignity of his profession by meeting the coupon man in his methods. The coupon man flourishes and cleans up the town; or, if the town or city has a large artistic trade, he continues for a longer time, unless he is a man, pure and simple, in which case he lasts quicker. All the time he is benefiting by the standard established and maintained by Smith. To whom is the coupon man indebted for his success? I think to Mr. Smith. So it is all over this land. We have the art-loving photographer, giving his life to the study of elevating the photographic business, and getting the price up to the point where he can conscientiously put the time and expense into a picture that will make a work of art, rather than a mere photograph, ground out as machinery; and we have ever present the coupon man, reaping a harvest by reason of the existence of the art-loving photographer.

Why are we to get rid of the coupon galleries, and such commercial schemes that tend to degrade the photographic business? It cannot be done by legislation, for that has been tried. It must be done by any other means permanently, except by legislation, by discouraging it in all our convention talks, in our club meetings. Make a thorough canvass of all the photographers in every city, get them to organise into clubs, and in your club meetings, discuss all subjects that tend to exalt and dignify the photographic business as a business. Do not believe in unionism as most other craftsmen organise themselves into, but I do most heartily believe in fraternal

organisations among our craftsmen; and let us there discuss our needs, and let each individual photographer learn that what helps the fraternity at large helps him individually, and anything that tends to destroy the greatest possibilities of our beloved art also hurts each individual member of our fraternity. After you become acquainted with your fellow-photographer in the club meetings you will find that your competitor, and possible enemy, is not a bad fellow after all, and really has many good qualities about him you never dreamed of before, and you will soon become friends, and ready to help each other, instead of doing dirt one to the other. It will not be long until you all agree on the very points we are now discussing. Is there any other class of business men who are so much inclined to avoid each other as the photographic fraternity? I cannot think of any, and yet my observation has been that when they do get together, as I have seen them, not many miles from Seattle, there is no class of men who stand together better, or who really agree more thoroughly, and enjoy themselves in company with their fellows more completely, than do the photographers. There seems to be a bond of sympathy that does not exist among any other class of business men. I have had photographers recently say to me that the time was past when a photographer could sit down in his studio and wait for his customers to come to him, unless he is content to make only a very meagre support. If he has any aspirations to accumulate any considerable amount of money he must adopt the popular method of going after his customers. If this be true, there is but one thing that has made it true, namely, the greed of a certain class of photographers. They have spoiled the public until they (the public) are expecting something for nothing, and the man who does a high grade of work is confined to such a limited few for his customers that he does not accumulate any great amount of filthy lucre. There is a class of people who will not be induced by advertising schemes to take a risk of getting anything satisfactory at one of these commercial picture machines. But the trouble is the mediocre class of people stand ready to get a bargain in everything that offers, and they are equally ready to bite at a photographic bargain. Now, I am not a pessimist, and do not think for an instant that we are going to the eternal "bow-wows," or anything of that sort. On the contrary, I am very much of an optimist, and very hopeful; I am inclined to think that, if you give the calf long enough rope, it will finally choke itself to death. But it may take quite a while to accomplish this end, and I, personally, would like in my lifetime to see the dear old photographic business elevated to a high pinnacle of grandeur that all lovers of the beautiful in art will be proud to take off their hats to it, and honour the men and women who toil under its banner, striving to get, through the aid of its scientific methods, the best possible results in the portrayal of the human face and form.

A. L. JACKSON.

## A MASTER IN CHILD PORTRAITURE.

Under this title there appears in a recent issue of the "Quiver" a most interesting account of the work of Mr. Richard Speaight in child portraiture, illustrated with nearly a score of the portraits which have brought to Messrs. Speaight's studio the little ones of the best families in the land. No less interesting than these photographs and the letterpress relating to them is the account given by the writer, Mr. Gregory Blyth, of the many charitable movements in which the Speaight Bros. have taken an active share.—Eds. "B.J."]

It is old saying that "The child is father of the man" was never illustrated than in the extent to which child-photography has held a permanent and predominant hold on the artistic world the last few years. From the early days of the daguerreotype and our immediate forebears have delighted in the pictures of life which the camera has been able to produce, whatever their merit may have been. At country fairs one may still obtain a type by the wet process, which represents the lowest scale of photography; at the other end are the beautiful pictures pro-

duced by a happy combination of the camera and that increased knowledge of and sympathy with children which is one of the most marked phases of modern thought. We have got beyond the Sandford-and-Merton stage in our ideas of what the child is and what he should be, and our better understanding of him finds expression in the photographs with which we love to surround ourselves in our homes.

One of the most successful workers in this branch of photography is Mr. Richard Speaight, who combines in himself the qualities of a photographer, a psychologist, and a philosopher. He is all three in

one, and it is difficult, as one glances over his gallery of beautiful children, to say which quality is uppermost, for it is certain that his personality plays a great, if not the greatest, part in his work. However expert he may be in the use of the camera, it would be almost impossible for him to obtain such good results were it not that he has made a thorough study of child-nature, and is able to divine by sympathetic intuition the curious thoughts and fancies that flit through the childish brain.

His method of portraiture is at once original and distinctive. He never follows the old-fashioned method of placing a child stiffly on a chair—oh, those horsehair chairs that pricked our tender skin—and telling him to smile while he clicks the shutter. His object is to get to the soul of the child by bringing himself down to the little one's level.

In his studio he has a large collection of comic and mechanical toys suited to the tastes of children of every age. Year by year, as new novelties are introduced into the market, these are replenished, and the children's ideas of amusement are gauged by frequent visits to children's plays such as "Peter Pan" and other entertainments, and by studying the thousand and one children's books that are produced every Christmas. Thus equipped, Mr. Speaight feels that he is in a position to know what his little client requires, perhaps better than the mother herself.

His first object in taking a photograph is to amuse. He makes the child feel at home by awakening his interest in toys or picture books, or even by gambolling about on the carpeted floor of the studio. The camera itself appears to play the least part in this merry little frolic, but at the proper moment, when the eyes of the child open wide at some new wonder, and a smile of delight is passing over his face, the bulb is pressed, and that transient gleam of child-nature has been transferred to the sensitive plate.

By following this method Mr. Speaight has been eminently successful in child portraiture. He finds it difficult, he says, to explain where his success actually lies, but we have no doubt that his kind-hearted personality has as much to do with it as anything else. To hosts of little ones, ranging downwards from the children of the Royal Family, he is a fond and familiar figure. Many of them know him as "Uncle," and to others he is simply "The Cuckoo Man," thanks to a mechanical toy which plays a great part in his little photographic drama. Not long ago a child who had visited Mr. Speaight's studio was driving past the doors in Bond Street with his grandmother, when he insisted on having the carriage stopped, and took in the old lady to be introduced there and then to his friend "The Cuckoo Man."

It would seem as though the work were second nature, a sort of instinct which took its place before the mechanical manipulation of the camera, for Mr. Speaight modestly owns to an immediate success in this branch of his difficult art. Within two years of his making a specialty of child portraiture he had been called to every Royal palace in the United Kingdom. Since then every Royal babe, except perhaps the youngest, has been photographed by him. He has taken children when they have been only five days old, and in many cases those who came to him as little ones have in course of time brought their own babies to him for picture purposes.

At Sandringham and Osborne he is a well-known figure, and a prime favourite among the Royal grandchildren. He tells with delight how some few years ago he suddenly received a Royal command to attend at Sandringham on Christmas Day for the purpose of photographing the little princes and princesses. Singularly enough, he was rather short of apparatus at that particular time, for business pressure had not left him sufficient leisure to collect the newest toys that were on sale in the shop windows. He knew that it would be useless to take down any of the old stock, for children are keenly

alive to changes of fashion in the toy market. The only resource open to him was to borrow from his friends, and this he did, going round hurriedly in a cab and collecting from all who would be sufficient of the season's novelties. Armed with quite a little lot of amusing and mechanical treasures, he rushed down to Sandringham. He succeeded admirably with his pictures, and delighted the Royal Family with his artistic representations of the little ones who were gathered at the King's Norfolk home for the Christmas festivities.

Mr. Speaight says that he finds it essential to the success of work that he should take complete charge when photographing children, whether of the Royal Family or those of more humble station in life. Princes and princesses, royal dukes and duchesses, he sometimes is to be told to "stand aside" when "Uncle" is about, very often he is unable to obtain the best results unless he can work along his own lines without interference from the parents. His successful he has been may be gathered from the fact that year after year some children come to him for portrait purposes, and in many families there has been established what is known as the "Baby Book," in which the little ones appear at the various stages of their growth and development. The Crown Princess of Sweden, the Duke of Connaught's daughter, has one of these volumes, which no one is allowed to handle but herself. Mr. Speaight once offered to place his pictures in it for Her Royal Highness, but the Princess declined, saying, "I will do it myself."

During the last ten years Mr. Speaight and his firm have thrown considerable energy into various movements having for their object the raising of money for charitable purposes, with the astonishing result that during that period they have been the means of collecting upwards of £85,000. Their first effort was in connection with the starting of the King's Hospital Fund, when they originated the Roll of Ministering Children, with the object of raising £20,000 towards aiding his Majesty in putting the finances of the London hospitals on a sound footing. The King, who was then Prince of Wales, took a keen interest in their work, and as a preliminary step he gave instructions that all his grandchildren should be photographed by Mr. Richard Speaight in order to assist the movement. In addition His Royal Highness visited at the Crystal Palace the exhibition of portraits of Royal children that Messrs. Speaight were holding at that time. Another great charitable effort with which they were associated was the Imperial Coronation Bazaar at the Royal Botanic Gardens, one of the most brilliant exhibitions ever held. The whole of the work was designed by Mr. F. W. Speaight and it will be remembered that the opening ceremony was the first public act performed by Queen Alexandra after she came to the throne. So successful was the movement that the receipts for the three days on which the fête was open amounted to £27,000.

It was a noble response, but the sum only inadequately represented the energy and sympathy which Mr. Speaight and his friends put into the work. He is never so happy as when he is with the little ones, listening to their quaint sayings and watching their quaint ways. Every sentence carries its lesson, every action has its meaning, to be stored up and remembered against the time when a new and complex problem in child portraiture—and these are always occurring—crops up in the studio. In many ways each child is a law unto himself. He has his own particular whims and fancies; he follows his own line of thought, and translates this into action which is sometimes of a novel and startling nature. Precedent may count for little in estimating what he will think and what he will do at any particular moment or on any special occasion. But sympathy is the sure key to his understanding, and no one knows better how to use it than Mr. Speaight, an artist among photographers.

MR. ROBT. W. PAUL has found it necessary, owing to the development of the cinematograph business, to secure a general manager for this department, and has appointed Mr. J. W. Smith to this position. Mr. Smith is well and favourably known to every exhibitor, having until now managed, under Mr. Will G. Barker, the business of the Warwick Trading Company. Previous to this he was with Mr. Paul for about six years, before which he was with Mr. Walter Gibbons (who made so well known the bi-tableaux exhibits with the Randvill machine), David Devant (now

Maskelyne and Devant), and Horace Chester, the lecturer whose dioramic effects with the triple lantern, which Mr. Smith worked were a notable form of entertainment. Thus Mr. Smith has a thorough knowledge of the requirements of the up-to-date showman, as well as extensive experience in taking scenes at home and abroad. He is an enthusiastic cinematographer, and boasts that he has never yet failed to fulfil a promise to a prospective customer or disappointed an exhibitor in the delivery of a film, whether in England or abroad.

# OTOGRAVURE FOR THE PROFESSIONAL PHOTOGRAPHER.

## II.

plate has been dusted sufficiently by its three or four visits to the dusting box, it should appear like a piece of beautiful brown velvet with a perfectly even "pile" or nap of quite an appreciable thickness. This grain must now be fixed by heat. The edge of the plate is held in a small hand vice, which should have a slip of thin leather tied to the upper jaw, to prevent the teeth scratching the edge of the plate; a lighted spirit lamp is now carefully waved beneath the plate to heat it uniformly, so that each grain of the plate shall melt and be fixed. Great care must be exercised in this process, as over-heating may cause the particles to run together, forming bubbles. The beautiful brown velvet appearance changes to a blue steely bloom as heat is applied, shrinks, and becomes a blue steely bloom. As this point is reached, the lamp must be withdrawn and the plate allowed to cool. It is now ready to receive the "resist," which is a carbon from the reversed transparency, and is there-fore reversed negative. It may be printed in a special photo-tissue, but red chalk or portrait brown will do as well. For the final working of the process, a gelatine film without any pig-ment would fulfil the purpose, but it would be difficult to gauge the film for printing for the resist. To secure that the picture shall be reproduced on the copper plate, it is necessary that the deepest shadows should be represented by practically bare copper, the deeper tones by a thin film of gelatine, increasing in thickness till the highest lights are represented by an appreciable film of gelatine.

### Etching the Plate.

The mordant or etching fluid is a saturated solution of iron peroxide; it must be so saturated that it cannot part with any more iron, so as to soften the film of gelatine, so that it can only attack the copper where it is not protected by any gelatine—that is, the deepest shadows. When the mordant is poured over the plate, it at once begins to eat away the copper in the deepest shadows, which become deeper in about three minutes it will be noticed that now new places are being attacked, that the thin film in the dark tones is resisting the etching fluid; it is therefore poured off, and a slightly more concentrated solution poured on. The area of attack is now enlarged, and the copper appears as the copper is attacked; in a few more minutes more dilute solution is used, and so on until the whole of the plate is blackened, even the highest light. The full process of etching should be complete in from fifteen to twenty minutes. The etching should be allowed to darken for about thirty seconds before the etching solution is poured off, and the plate washed with a solution of potassium carbonate, which at once stops the action of the mordant. The plate may now be washed, the film of gelatine rubbed off with a nail-brush, and the plate cleaned off with turpentine. If a little lamp-black in oil, or an artist's colour is rubbed into the plate, and the surplus is wiped off, a good idea may be obtained as to the success or failure of the etching. The deep shadows should have a rich velvety look, the rest of the colour in them, while the other tones should appear in proportion, but all much darker than seems correct, owing to the colour of the copper beneath. An impression can be taken on one of the wringing machines with rubber rollers, generally found in most households, is used. Or a friendly printing house will give a copperplate printer on their premises who will pull a proof.

### Inking-up the Plate for First Proofs.

It is decided to try the wringing machine or the family mangle, a board of flat board some inches larger than the plate will answer the purpose on which to lay the plate. Some pieces of thick, smooth board the size of the board will be needed (the professional printer uses pieces of undyed broadcloth); two of these are laid on the board, and two pieces of ordinary new scouring flannel on the board and the "blankets" are inserted between the board and the screws adjusted to give a good pressure, which must be equal on both sides. To test for unequal pressure, turn the board so that the board projects far enough to lay the trial plate on. When the blankets are turned up; a piece of any ordinary paper large enough to more than cover the plate is laid upon it, the board laid down, and the handle turned so that the board and the

plate are drawn between the rollers. If the piece of paper is now examined it will be seen by the depth of the "plate-mark" if the pressure has been equal on each side. The engraved plate is then warmed and some printer's ink rubbed in with a rubber made of a roll of flannel as described for polishing the plate, but the end should have a piece of wash leather tied over it to prevent the flannel wearing away and leaving bits on the plate. The ink must be well rubbed into the warm plate, and, as the latter cools, the surplus is wiped off with a piece of rag. Finally, the whole surface is polished with the fleshy part of the hand, till no ink is perceptible on the light parts of the subject; a small film of ink will, however, be left, which gives just a tint to the lights, unless the hand is rubbed with whitening before giving the last few strokes of polishing. The edges of the plate should be wiped with a piece of rag rubbed on a ball of whitening, and held firmly over the end of the thumb. The plate should then be warmed again, laid on the board forming the bed of the press, and a sheet of damp paper laid on the plate, the blankets laid over it, and the whole "pulled" between the rollers, as in testing the pressure of the press. The paper is then lifted off and the print examined to see what quality of plate has been made. The first attempts at printing should be made on "plate" paper, an unsized make specially prepared for copper-plate printers. It can be damped by laying it in a dish of clean water, and blotting off between blotting paper, with plenty of pressure, for there should be no moisture on the surface. If a sized paper is used, it should be dipped in water overnight, laid in a pile, and wrapped in a towel to keep it moist, and blotted off in the morning. Before being placed on the plate it should be well brushed with an old clean hair brush, and the huff dusted off with a goose's wing, which may be "commandeered" from domestic sources. The inking rubber and also the polishing rubber should be kept wrapped up in clean paper to avoid grit, which might produce scratches on the plate.

If the first few trials have been successful, an attempt may be made to do serious work. Having decided on the size of the reproduction, copper plates should be procured of the necessary size allowing from half to one-quarter of an inch at sides and top, and at least double that width at the bottom. The negatives must be safe-edged before the transparency is printed. When the latter is obtained it should be varnished with celluloid varnish, and masked accurately to size; the edges of the masking must be straight, and the angles properly square. It is better to use opaque paper, such as orange or red, upon which ink lines may be ruled about one-eighth of an inch or more as may be found convenient from the inner edge of the masking. The sensitised red tissue is cut exactly to the size of the space enclosed by the lines, and placed accurately within them, marking the top of the picture upon the back of the tissue.

### Printing Precautions.

A trial exposure must be made on a small piece of the tissue and developed upon a piece of opal glass to secure an exactly accurate depth of printing, which should be sufficient to give all the gradations in the highest lights, but leaving the few touches of deepest shadow bare to the opal, on development. The plate having been grained in the dusting box, the grain fixed by heat, and the plate cooled, it is ready to receive the carbon image. It will be best to use boiled water which has been cooled for putting the carbon tissue on to the grained plate, as air-bells cling obstinately to the rough surface of the plate, and even a very small one is fatal to success. For we must have a perfect negative image in gelatine. All air-bells must be brushed from the wet tissue, and when it has absorbed the right amount of moisture it is laid down in the proper position on the copper, leaving equal margins at sides and top, and the larger one at bottom. It is for this purpose that the top of the picture is marked on the back of the tissue. An expert carbon printer will, of course, manage this part of the work with ease. The plate should remain covered with blotting paper, under pressure, for about twenty minutes. Development must be carried out with great care, because if the paper backing is stripped off too soon the image will leave the copper. If it is left too long, patches of circular marks, suggesting air-bells between the tissue and plate, will shade and spoil the picture. The backing should be removed at the earliest moment that is safe.

### Development of the Gelatine Resist.

Fairly long development in warm water, not rapid development in hot water, is best; roughly, the temperature should not exceed 100 degrees. Every particle of soluble gelatine must be washed from the plate, leaving just a few touches here and there of bare copper, representing the deepest spots of shadow. When development is complete the plate should receive a good rinsing under a gentle flow of water, and to prevent uneven and prolonged drying, methylated spirit should be poured over it, from an open measure (in such a way that it sweeps right across the plate), not from a bottle, otherwise a film or scum of gelatine comes away with the first flow of spirit, and will cling in strings to the surface and spoil the image. It is better to etch a plate as soon as it is dry, because there is danger in keeping it, partly from fingering, which makes greasy marks, but chiefly because if the plate is kept for some hours in a dry atmosphere the film will crack off the plate and the whole work has to be done over again. For if anything goes wrong with the carbon image the bitumen grains must be removed and the plate cleaned and repolished. A careful examination of the plate should now be made, and if there are any defects in development, uneven grain, or any of the thousand and one trifles that spoil a carbon print, it is no use etching it. Tiny pinholes may be spotted out with stopping-out varnish, but all such spottings mean white marks on the print, unless touched out with the burin or graver, on the plate. The margins of the picture and the back of the plate must now be protected. Although expensive "stopping-out" varnishes are recommended there is nothing better than good shellac varnish of the drysalter. To each pint should be added an ounce of green lacquer, so that the parts of the plate covered by the varnish can be seen at once, as the green colour shows up at once on the red copper and red carbon image.

### Marking up the Plate.

The edges of the picture are the most important and most difficult part to protect, as the lines must be straight and the corners right angles. First of all, a line must be ruled with an ordinary ruling pen charged with the green varnish. A pen well used in an architect's office is best, or if such a one cannot be secured, a new one should be rubbed carefully on an oil stone to take off the sharp cutting edge of a new pen, which will tear the gelatine film. A thin steel rule makes the best straight edge, and it can be held on the plate on the margins so that the picture is not touched, for the gelatine image is almost as tender and delicate as a butterfly's wing. The line of varnish should quite cover the edge of the picture, and any errors in the masking may be corrected. To ensure the lines being at right angles to each other a piece of stout cardboard should be ruled with fine ink lines about half an inch apart, at right angles, so that the card is divided in half inch squares. If the plate is laid on the cardboard (which should be twice as large as the plate), with one of the edges of the picture coinciding with one of the lines on the card, the straight edge may be adjusted, and a line drawn with the pen, running across the margins, then without moving the plate the card is turned round and the ruled adjusted to the margins, and to one of the lines on the card, which are, of course, at right angles to the line first drawn, and so on till the picture is enclosed in four fine lines of green varnish. A small sable brush—an old spotting brush answers admirably—can now be used to paint the varnish up to the fine line, then a larger brush is used to cover up the rest of the margins and the back of the plate, which also needs protection. The plate is now ready for etching, and some account must now be given as to the preparation of the solution.

### Preparing Etching Solutions.

Many authorities recommend a set of solutions ranging from 45 degrees to 30 degrees on a Baumé hydrometer for dense liquids. But if photogravure is not part of the regular work of the photographer, it will be found better to make up only one solution, the strongest that will be needed, 45 degrees Baumé, and use just enough to cover the

plate, and when it has done its work a few drops of warm water put into a small beaker, and the solution from the plate poured out. It is then returned to the plate and the second etching given. A few more drops of water put into the measure and returned to the plate, and so on. After each addition of water the density of the solution should be tested with the hydrometer. Then the plate is etched all over. The iron perchloride solution should be kept away and not returned to the stock bottle, because it has been found by some workers that a solution, of which part has been used and returned to the bulk, loses its power when used again some time later, and although it appears to act in the usual way, blackening the copper and apparently eating it away, it may be found that in clearing off the gelatine resist that the biting is so shallow as to be less. This uncertainty is avoided by using the solution once only.

The etching solution seems to improve by keeping, for a few days, but occasionally produce what are known as "devils," irregular star-shaped fissures in the copper, which may, and often do, entirely ruin an otherwise perfect plate, for they cannot be removed, as they hold a good depth of ink they print quite black. They sometimes come all over the face of a portrait. A solution that has been made up and kept for a few weeks will rarely produce a crop of devils. They are one of the terrors of existence of the photogravure artist. All suffer from them at times, yet each has his own infallible remedy, which often fails at a critical moment. The "devils" certainly deserve their name.

The solution is made by dissolving solid iron perchloride of iron in water; about 1½ lb. of perchloride to one pint of water. An enamel saucepan must be used, as the solution will attack iron. When cooled to about 70 degrees it must be tested for strength with the hydrometer, and if it registers less than 45 degrees the boiling should be continued until sufficient water has been evaporated to increase the density to the required degree. A few ounces of the solution should be put into a beaker and liquid ammonia stirred in until hydrate of iron begins to be precipitated. It should be filtered out, washed with ammonia, and added to the bulk of solution. This addition is made for the purpose of neutralising acidity, and the solution should be again boiled. An excess of hydrate will do no harm, and prevent acidity. When the solution is cold it can be allowed to stand for some days, the clear part decanted, and the remainder filtered and stored for use.

When a good plate has been secured, as few proofs as possible should be taken from it, as the copper is soft and the depth of etching is slight, that even pulling half a dozen prints may cause a perceptible amount of wear, since the friction of inking and polishing the plate is considerable. It is best to send it to a printer of etchings, such as Messrs. Annan, of Glasgow, or Messrs. Brooker, Margaret Street, W., who will "steel face" it by electro-depositing iron upon it. This greatly prolongs the "life" of the plate. The prints received from such firms will surprise the new hand, who naturally cannot hope to secure a long time to secure the best a plate will give. Skillful workers improve a plate by working upon it, but only to a very limited extent, and a bad plate can never be made into a good one. Small varnish marks must be removed with a graver, but this is beyond the amateur and must be left to a professional engraver. Small patches of copper can be lightened with a burnisher, larger patches by rubbing with willow charcoal, using the end of the grain at an angle. Small parts can be darkened with the roulette, a small wheel or roller covered with fine teeth, which is rolled over the parts to be darkened, but such work requires considerable skill and no little experience.

A good photogravure print has no rival among photographic printing processes, and certainly it is the finest of all reproduction methods, but as the process is difficult it cannot be regarded as a cheap way of multiplying copies.

Photographers who have a little spare time might do much more than taking up the method, and they will find it most fascinating. Its very difficulties give a zest to the work.

HAROLD BAKER.

A GUIDE TO THE DANUBE.—The Danube Steamship Co., Vienna, which maintains a regular service of steamers from Passau to the Black Sea, and on to Constantinople, sends us the illustrated prospectus of the tour which can thus be pleasantly and conveniently

made from Southern Germany to Vienna, Budapest, Belgrade, Orsora, and Galaz. The romantic scenery and turbulent storms which lie upon the journey provide the materials for a photographic holiday out of the ordinary.

# BENZIN, BENZINE, BENZENE, BENZOL, BENZOLE, AND BENZOLINE.

so much confusion is introduced into photographic formulae and prescriptions by the careless use of the words benzol, benzine, and benzene, which appear in the "Chemist and Druggist," under the above title. We cordially endorse the writer's suggestion that the term "benzole" be kept for the coal body, and "benzine" or "benzin" for the light liquid obtained

from petroleum.—Eds. "B.J."]

confusion seems to exist between these terms, and the recent years similar to them that we reprint the article by Otto Raubenheimer, of New York, which appears in the "Chemist and Druggist," under the above title. We cordially endorse the writer's suggestion that the term "benzole" be kept for the coal body, and "benzine" or "benzin" for the light liquid obtained from petroleum.—Eds. "B.J."]

From this chaos in Great Britain we cross the ocean, and in the new land, America, we get new ideas. Here there is no confusion between the petroleum and the coal-tar products, except in some old books. Mitscherlich's term "benzine" for benzole was discarded over here long ago. Benzine to-day, and for a long time in U.S., means always petroleum benzin, while benzole is the name for the coal-tar product  $C_6H_6$ , and thus these two terms can be readily distinguished. The United States being the home of the American petroleum or crude oil, benzine is very cheap (about 15c. per gal. = 128 fluid oz.), and is used extensively, particularly as a cleansing fluid. However, the American, as well as foreign, druggists sometimes get confused on the difference between benzin, naphtha, and gasoline. In a paper read before the American Pharmaceutical Association in 1905 I described a simple method of distinguishing these three similar hydrocarbons—namely, by their sp. gr. or Baumé hydrometer reading. Benzole C.P., crystallisable  $C_6H_6$ , costs, on the other hand, 75c. per gal. It is used but little—in fact, is little known by the laity. Very few druggists indeed sell benzole. The much-confusing term "benzoline," I am glad to say, is not known or used in the United States. Formerly, and to some extent even now, the word in "petroleum benzin" was written "benzine," which name was, for instance, persistently used by the manufacturers, the Standard Oil Company, who have, however, now changed it. The brand formerly known as 62 deg. benzine is now called P. & V. M. naphtha (painters' and varnish-makers' naphtha). This change in name very likely was made to comply with the Pure Drugs Act, as the brand is not identical with U.S.P. benzin. The term benzole was also formerly written benzol. This is how the change occurred. The American Association for the Advancement of Science, at its meeting in 1887, appointed a committee to consider the question of attaining uniformity in the spelling and pronunciation of chemical terms. The work required extensive correspondence and detailed discussion exhausting over four years, when in 1891 rules were adopted by the Association and recommended to chemists generally in the hope that they would cordially unite in the efforts to bring about uniformity in usage. The following rules pertain to benzin and benzole:—

1. The end syllable "ine" should be used exclusively for alkaloids. In neutral bodies the final "e" should be dropped. "Benzine" should be "benzin."

2. Terminations in "ol" should be used exclusively for alcohols.

3. Terminations in "ole" ; its use is limited to compounds which are not alcohols—for instance, "benzole."

4. Among the list of words which should be avoided in favour of the following synonyms, we find glycerin=glycerol, benzol=benzene. For this reason the U.S.P. VIII. adopted the following nomenclature: benzinum=petroleum benzin; benzene or benzole,  $C_6H_6$ .

Judging, however, from the correspondence in the "Chemist and Druggist," the confusion between the terms benzine, benzole, and benzoline in England is very great. Therefore why not use Faraday's term "benzole" for the coal-tar product, and the term "benzine," or, still better, "benzin," for the petroleum distillate? Thereby all confusion would be avoided.

OTTO RAUBENHEIMER.

day gave this liquid the name "bicarburet of hydrogen," the formula being  $C_{12}H_6$ , which, of course, has since been changed.

About the same time Eilhard Mitscherlich, Professor of Chemistry at the University of Berlin, obtained the same liquid by distillation of a mixture of benzoic acid and lime. Mitscherlich called the name "benzine"—benzoin-like, on account of its odour. Faraday, however, objected to this name, especially the syllable, "ine," as being too similar to the distinctive name of alkaloids. Faraday accordingly called this liquid "benzole." French, however, adhered to Mitscherlich's name, and even called benzine "la benzine." Thus Violette, in "Dictionnaire des Chimiques," 1851, Vol. I., p. 152, says "Benzine voyez Benzole."  $C_{12}H_6$  syn.: benzine, benzène, phène." It is not unusual to find the English translation of a French article of benzine, when the French original states "la benzine," means benzole.

Italy we also find confusion regarding these terms. Orsini, "Acologia Italiana," states, p. 1549, "Benzola-benzina, pheno-

benzola  $C_6H_5H$ ; p. 1610, under petroleum distillates, benzina, benzolina, nafta, etc., sp. gr. 0.720."

is one Continental Pharmacopoeia, the Portuguese, which gives the official title "benzinam" to a benzole of sp. gr. 0.85 pt. 85 deg.

Germany, Austria, and other countries there exists no confusion. In Germany benzin is called "benzin." The official title in D.A.B. IV. is petroleum, and in Ph.Aust. III. is æther. petroli. Coal-tar, on the other hand, is named benzol; official title, "benzol," sp. gr. 0.880 to 0.890, and b. pt. 80 deg. to 82 deg. The "Pharmacopoeia" (supplement to Germ. Pharmacop.), on p. 414, gives as a synonym for benzolum the name "pyroleum benzin," which is the official title for a rather impure benzole in the German Pharmacopoeia. In all German-speaking countries it is understood that benzin means petroleum benzin, and benzol coal-tar benzene.

When we cross the Channel to Old England, there we find great confusion. We not alone have benzine, benzene, and benzol, but have found benzoline. In the first place we have the British Pharmacopoeia "benzol." This is a mixture of homologous hydrocarbons obtained from the light coal-tar oil. It contains about 70 per cent. benzene,  $C_6H_6$ , and 20 per cent. to 30 per cent. toluene,

$C_6H_5CH_3$ . This pharmacopoeial benzol is used as a solvent in the preparation of charta sinapis and also liquor caoutchouc; besides, the commercial benzol is the starting-point in the preparation of aniline dyes, etc. Among the English literature on the confusion of the terms benzine, benzol, and benzoline, I select the following: A. H. Allen, in the "Analyst," 1879, No. 43, and in the "Chemist and Druggist," 1880, p. 386; Proctor, "Pharmaceutical Testing," p. 6; MacEwan, "Pharmaceutical Formulas," 1899, p. 299; Hurst, in "Garment Cleaning"; and McGowan, in his translation of Meyer's "History of Chemistry," p. 457—all show confusion of the terms.

From this chaos in Great Britain we cross the ocean, and in the new land, America, we get new ideas. Here there is no confusion between the petroleum and the coal-tar products, except in some old books. Mitscherlich's term "benzine" for benzole was discarded over here long ago. Benzine to-day, and for a long time in U.S., means always petroleum benzin, while benzole is the name for the coal-tar product  $C_6H_6$ , and thus these two terms can be readily distinguished. The United States being the home of the American petroleum or crude oil, benzine is very cheap (about 15c. per gal. = 128 fluid oz.), and is used extensively, particularly as a cleansing fluid. However, the American, as well as foreign, druggists sometimes get confused on the difference between benzin, naphtha, and gasoline. In a paper read before the American Pharmaceutical Association in 1905 I described a simple method of distinguishing these three similar hydrocarbons—namely, by their sp. gr. or Baumé hydrometer reading. Benzole C.P., crystallisable  $C_6H_6$ , costs, on the other hand, 75c. per gal. It is used but little—in fact, is little known by the laity. Very few druggists indeed sell benzole. The much-confusing term "benzoline," I am glad to say, is not known or used in the United States. Formerly, and to some extent even now, the word in "petroleum benzin" was written "benzine," which name was, for instance, persistently used by the manufacturers, the Standard Oil Company, who have, however, now changed it. The brand formerly known as 62 deg. benzine is now called P. & V. M. naphtha (painters' and varnish-makers' naphtha). This change in name very likely was made to comply with the Pure Drugs Act, as the brand is not identical with U.S.P. benzin. The term benzole was also formerly written benzol. This is how the change occurred. The American Association for the Advancement of Science, at its meeting in 1887, appointed a committee to consider the question of attaining uniformity in the spelling and pronunciation of chemical terms. The work required extensive correspondence and detailed discussion exhausting over four years, when in 1891 rules were adopted by the Association and recommended to chemists generally in the hope that they would cordially unite in the efforts to bring about uniformity in usage. The following rules pertain to benzin and benzole:—

1. The end syllable "ine" should be used exclusively for alkaloids. In neutral bodies the final "e" should be dropped. "Benzine" should be "benzin."

2. Terminations in "ol" should be used exclusively for alcohols.

3. Terminations in "ole" ; its use is limited to compounds which are not alcohols—for instance, "benzole."

Judging, however, from the correspondence in the "Chemist and Druggist," the confusion between the terms benzine, benzole, and benzoline in England is very great. Therefore why not use Faraday's term "benzole" for the coal-tar product, and the term "benzine," or, still better, "benzin," for the petroleum distillate? Thereby all confusion would be avoided.

OTTO RAUBENHEIMER.

## THE L.C.C. SCHOOL OF PHOTO-ENGRAVING.

THE report of the twelfth session of the "Bolt Court School," presented by the Principal, Mr. A. J. Newton, to the London County Council in January last, and now produced as a handsome volume, gives the following particulars showing the continued progress of the school:—

"The total number of individual students who entered during the session was 567, as compared with 565 in the previous session. The maintenance of our numbers is extremely satisfactory, in view of the fact that the attendance at most technical institutes does not appear to have improved in numbers last year, except where new classes had been started.

The position of the students can be classified as follows:—

	1905-6.	1906-7.
Under preliminary training, apprentices, learners, and improvers .....	304	306
Assistants and journeymen .....	157	174
Managers and foremen .....	14	10
In business for themselves .....	90	77
	565	567

The average age was 22.8 years.

We had students from 226 different firms, 17 firms sent from five to twelve students each, and one firm sent twenty students.

The following summary shows how the activities of the students have been distributed:—

	1905-6.	1906-7.
Individual students entering only for photo-engraving classes .....	319	336
Individual students entering only for art classes .....	152	126
Individual students entering for both photo-engraving and art classes .....	54	52
Individual students entering for both lithographic and art classes .....	12	17
Individual students entering for both photo-engraving and lithographic classes .....	7	2
	565	567

The character of the work done in the photo-engraving classes has been fully maintained. We have simplified considerably the methods of three-colour block-making, and the demand for instruction in this work continues as great as ever.

In the lithographic classes the work has been very satisfactory. In Mr. Baxter's class the quantity of work turned out is rather less than last session, but the average quality is better. Fifty-three colour jobs in from three to ten printings have been executed, and thirty in black only. About 400 stones were used. In Mr. Howard's class the work has also been satisfactory, and the attendance has been better than last year. There have been about 100 stones drawn.

An Advisory Sub-Committee for the School has been appointed by the Council, and the first meeting took place on Tuesday, February 12, 1907. The following members were appointed:—Mr. D. Cameron-Swan, Mr. Leslie E. Clift, Mr. A. E. Dent, Mr. Carl Hentschel, Mr. C. T. Jacobi, Mr. W. Stevens, Dr. C. E. Kenneth Mees, Mr. F. C. Tolhurst, Mr. Emery Walker, Mr. H. Snowden Ward, and since then the committee has been strengthened by the addition of Mr. T. R. Way, representing lithography, and Mr. Will Rothenstein, a representative artist, and Mr. J. Diviani, representing the Process Engravers' and Lithographic Artists' Society. There is no doubt that this committee will be of very considerable value to the school; already various members have made several important suggestions.

It is evident the trade continues to manifest its interest in the school, to judge by the constant applications I receive for technical advice, always freely given, and the inquiries for assistants. Further, the list of firms offering prizes has again been supplemented this year, so that now the best student in every department of our work has the opportunity of winning a prize value £2 2s."

The report, it should be added, is a publication of great technical interest, as it is made up almost entirely of examples of the various photo-mechanical processes prepared by students of the school. Of special interest are the impressions from half-tone blocks, taken on a paper containing no added mineral matter. The advantages, as regards both strength and absence of distressing surface-glare, are here clearly demonstrated, and the half-tone blocks are well rendered.

## THE HINTON MEMORIAL FUND.

WE give below a list of donations, additional to those published on our issue of May 1, for the above fund, further contributions which, however small, will be welcomed, and should be addressed to the hon. treasurer, Mr. Reginald Craigie, at 52, Long Ac London, W.C., marked "Hinton Memorial Fund."

## EXAMINATIONS IN CINEMATOGRAPHY.

second examination of cinematograph operators and exhibitors, is held under the management of a Joint Committee of the Cinematograph Manufacturers' Association of Great Britain and the Northampton Polytechnic Institute, London, took place at the Northampton Institute on June 29 and 30. The examiners were Messrs. Nevil Maskelyne and S. D. Chalmers. The candidates were successful in securing the higher certificate, and in securing the preliminary certificate. The names are as follows:—Higher certificate—W. G. Barker, London; H. Boddington, London; W. T. Coulson, London; L. D. Dickson, Edinburgh; J. E. Evey, Norwich; W. H. Hayles, Cambridge; W. J. Hogan, London; W. F. G. Jewell, London; G. A. Leonard, London; J. Neal, London; W. E. North, London; G. Palmer, London; J. Smith, London. Preliminary certificate—E. Kirby, London. Both grades of certificates the candidates have to pass an ant practical test; but for the higher certificate written questions are also required to questions set in the scope of the subject. In their report, the examiners state that the average standard was better than in the previous examination; and that all attention to the necessity for a thorough acquaintance with the L.C.C. regulations and the reasons for making them. They suggest that manufacturers be asked to mark resistances in such a way that operators may be led to appreciate the theory of the subject. They also suggest that those in authority over operators do all they can to impress upon their subordinates the importance of obtaining certificates of efficiency, and when opportunity occurs practical evidence of the value attached to a certificate may be given by showing a preference for the employment of only tested operators.

Following was the written paper, in which four questions (of which (1) and (6) had to be two) had to be answered:—  
1. You are required to project a 15ft. picture, using alternating current at 100 volts. What current would you take? Describe the apparatus, carbons, and fuses you would use, and show by a sketch how the connections are made.

2. Describe in detail your method of making the connections for a lamp of high power. State exactly what you do, and in what way to get the best possible light.

3. Describe the appearances on the gate (a) when the light is too close to the condenser; (b) when the light is too far to the left and too far down.

4. What focal length lens would you require to project a 12ft. picture with a working distance of 30ft.?

5. Describe the substance of the L.C.C. regulations about resistances, and the reasons for making these regulations made?

6. What would you do first and afterwards in the following emergencies:—

(a) The back member of the condenser broke and part fell into the lantern.

(b) The handle came off.

(c) The film took fire in the gate.

(d) The tube blew off the oxygen cylinder.

(e) The coal gas (hydrogen) cylinder was found to be empty half an hour before the show.

(f) You found the film to be the wrong way when you began to turn.

7. B.—Four questions (of which (1) and (6) must be two) to be answered.

8. You are required to project a 12ft. picture, using continuous

current at 200 volts, and are required to take as little current as possible. What carbons, fuses, and resistances would you use?

2. How would you test the quantity of gas in your cylinders? How much gas would you require to show a picture 10ft. diameter for one hour?

3. Give a sketch of the "gate" and mask; show how the light should come on the gate when projecting the film.

4. Describe how you would centre up the film and lantern slide. What should be the focal length of a lantern lens to be used with a 24in. focus lens? (Explain how you get your result.)

5. What are the L.C.C. regulations as to the use of lime light? Give reasons for these regulations.

6. What would you do first and afterwards in the following emergencies:—

(a) A spring broke.

(b) The re-winding belt came off.

(c) The fuse went.

(d) The bellows of the regulator burst.

(e) The shutter came off.

(f) A cry of "fire" in the hall.

## Photo-Mechanical Notes.

### A Photo-Litho Process.

ACCORDING to the recent specification (No. 6,093, of 1907), a patent has been taken out by P. L. V. Gaultier, of 45, Boulevard de la Republique, Versailles, France, for a process of photo-lithography, which consists of taking a print from the (collodion) negative of the subject on glazed paper sensitised with bichromate, which print is developed in water and lightly worked up with transfer ink. Inking and sponging are repeated several times, and the impressions then transferred to the printing surface. The following are details of the procedure:—

The negatives employed in the process are preferably collodion negatives, which give more delicacy than gelatino-bromide, particularly with line drawings, and also produce a great uniformity in intensity. For photography in colour the negatives of the primary colours are employed for the preparation of the three distinct printing surfaces necessary for lithographic printing in colours.

The photographic negatives serve to produce the transfer proofs. The latter are obtained upon paper covered with a sensitive film, such as gum, sugar, albumen, and other substances. Experience has proved that the substance which is best for the film is gelatine, and this substance should not contain any trace of grease, and should be hard and resisting when applied to the paper. The gelatines employed in the manufacture of gelatino-bromide plates answer well. For instance, those known as "Nelson's," "Heinrichs," and "Simeons," which are classed among the hard gelatines, can be employed, and even mixtures of these. If the gelatine is lacking in consistency a saturated 1 per cent. solution of alum can be added to the hot solution, this addition being made by introducing a small quantity at a time, meanwhile constantly stirring the gelatine. A 25 per cent. solution of gelatine is then prepared, the gelatine being allowed to swell for some hours and dissolved in the water bath. The solution is then filtered through a fine mesh material, care being taken to avoid the formation of froth or foam which produces air bubbles very difficult to get rid of later on. The filtered gelatine is afterwards maintained at a temperature of about 80 deg. C. during the length of the subsequent operation.

The paper which is covered with gelatine should be of very good quality, very resistant and glazed; it is advantageous to employ, for example, the makes known as "Rives" and "Steinbach." The sheets of paper are joined in pairs, back to back. These sheets are then plunged into the bath of dissolved gelatine, a suitable to and fro movement is imparted to them, and a series of slight shaking movements, in such manner as to uniformly deposit the layer of gelatine and to free the air bubbles attached to the paper. The sheets thus covered are then dried, being so arranged that they remain flat. Once dry, they are put up in a roll and kept dry, and protected from dust.

The gelatinised paper so obtained is then sensitised. For this

purpose a solution of bichromate of ammonia in water to 5 per cent. is employed, in which the sheets of gelatinised paper are immersed for about two minutes, and are gently stirred in order to moisten and to sensitise uniformly all parts. The sheets are then completely dried in a dark place or a room, properly lighted.

The sensitised paper thus prepared serves for printing the positive from the photographic negative. The exposure is made, as usual, in a frame, and preferably in diffused light, care being taken that the pressure of the sensitised sheet upon the negative is equal and sufficient throughout. The time of exposure depends upon the intensity of the negative and the strength of the light; electric light properly regulated will be quite suitable. When the image is satisfactory the print is removed from the frame and is developed simply in cold water, which is often renewed, especially in the commencement. This development should have a minimum duration of two hours, but it can be prolonged for a much longer time without ill effect.

The proof taken out of the water is drained and dried until it shows no further trace of water. The image is then formed by parts of bichromated gelatine, which, under the action of the light, have acquired the property of repelling moisture according to the intensity of the negative, whereas those parts which have been deprived of light and which consequently correspond to the opaque parts of the negative, are, on the contrary, impregnated with moisture and give up the bichromate which they contained. A gelatinised surface is thus produced having lithographic properties of stone or zinc. Then there is passed over the same sheet a special roller, charged very lightly with transfer ink, to which turpentine oil may be added in case the image appears with difficulty. This roller is an ordinary roller of white swansdown or "molleton," which is covered with ten layers of white flannel, after the swansdown has been brushed and cleaned several times with a liquid composed of alcohol and ether, and known by the name of "Hoffman liquid." This roller is passed very gently over the inked proof in an even manner in all directions, and over all parts of the image. Suppose, for example, that it has been operated over a line drawing, the latter is covered, more often than not, with a veil more or less dense, and the lines appear charged with a little ink. With a smooth sponge containing very little water, the veil is lifted and removed, the rubbing being done with precaution, until the background again becomes white, the lines being seen in dark grey. The flannel roller is again passed over, then the sponge, and these two operations are repeated several times in succession until the background of the picture refuses the ink, the lines becoming charged more and more with ink. A slightly wet sponge is then passed over the proof in order to remove from the lines small drops of water which they may hold.

The image thus obtained is left to dry, and when once dry possesses no cavities except upon the surface where the ink is deposited, which permits of it being transferred. The back of the picture is moistened and then wiped in such a manner as to remove the excess of water; the proof is then sufficiently flaccid to facilitate transference and sufficiently moist to permit the ink to be detached from the black parts of the image. The proof is then applied on a stone, rubbed with pumicestone, or a sheet of zinc finely grained, and is placed in the press and submitted to pressure three, four, or five times slowly and evenly. Then the plate of zinc is taken out and the transfer proof is removed. If all the operations have been properly conducted the ink is transferred to the zinc, and the proof which has served its purpose has again become white, and freed, or almost so, of the ink which it carries.

The transfer once finished, the plate is gummed lightly and then inked by the usual means employed in zincography. An advantageous mode of inking is by means of a greasy rag. The surface may be coated with bitumen and the latter sensitised; the image obtained is then very strong. The printing surface obtained can then serve for all subsequent prints, and can be preserved in the same conditions as the ordinary printing surfaces.

The surfaces from which it is desired to remove transfers have no need to be grained in this process, a simple scraping is sufficient, or they are treated with benzole, which dissolves the ink of the image, after which they are washed and dried. After this they are passed into a bath of hydrochloric acid or nitric acid, diluted to 10 to 15 per cent., and then washed. This concluded, they are plunged into a solution of cyanide of potassium in water, to the proportion of 10 per cent., where they are left for about 15 minutes, and then finally washed and dried.

When reproducing to the same scale a hand-made drawing or chart made upon thin paper or upon tracing paper, a negative print is made on paper, and this negative is treated and used as already described.

When, instead of reproducing a line drawing, it is desired, on the contrary, to reproduce a half-tone image, the operation is carried in the same manner, care being taken, however, to obtain a strong dense photographic negative, and to only expose the picture a short time; moreover, the rubbing off with a sponge is dispensed with.

In the case of pictures "en camaieu," produced by the superposition of several tones, the image contained in the negative is decomposed into two or three partial images, the superposition of which constitutes a single image. These partial images form separate printing surfaces, which are inked with the same colour, but of different tones. The only difficulty to be overcome is the procuring of the three necessary images which are derived from the same negative. These images of different tones are obtained by the difference of the times of exposure to the light of the gelatine papers. The times of exposure depend essentially upon the quality of the negative and the nature of the negative. Experience has, nevertheless, shown that the proportion between the times of exposure should correspond approximately to the following conditions:—

One unit of time for the print giving shades or background detail.

Two units of time for the print minus the weakest tones.

Three units of time for the print giving the very weakest tones.

The registration of the partial images should, moreover, be exact. It is possible, when these images are of small dimension, to transfer them on to the same zinc plate, leaving sufficient margin between them and then subsequently to separate them for printing in tracing upon the negative, before its exposure to the light, registering marks, consisting of finely drawn crosses, are drawn upon the three images. Their exact superposition in the subsequent printing guarantees the accurate superposition of the tones. In case one of the three images happens to be of a different size from the others a separate image may be made by means of prepared thin paper. For this purpose one of the images is chosen as a standard, and a proof card is pulled therefrom, and proofs upon prepared paper are pulled from the other plates. After having cut up the latter proofs on to fragments the fragments are applied to the proof on card, and are then registered with the standard image on the card in the ordinary manner; the assemblage of fragments makes up a complete image of correct dimensions. By a transfer conveniently made from these assembled pieces of paper, new transfer proofs are obtained, having exactly the desired dimensions.

For the production of coloured pictures the same method of section is observed. These monochrome proofs are first pulled, according to the usual processes, by the aid of screens, one giving the red, the second giving the blues, and a third the yellows contained in the object photographed. The superposition of these three colours constitutes the coloured image or picture. Three printing surfaces are thus produced corresponding to these colours, and the printing is then performed, the complete operation for each of the monochrome proofs being, as in the case of the reproduction of a line drawing, with an ordinary photographic negative. It is always indispensable that the pictures should contain absolutely the proper proportions of red, blue, and yellow that they require, without which, after printing, the colour would be found to dominate the other and the image or picture would be defective.

In the example described it has been supposed that a transfer proof has been made on to zinc, but other metals possess in different degrees lithographic properties of stone or zinc; for example, aluminium, ferro-nickel, silver-plated copper, and others.

#### PHOTO-MECHANICAL PATENTS.

The following patents have been applied for:—

SCREENS.—No. 15,021. Improvements relating to half-tone and other screens for photography. William Charles Masser and William Hudson, 18, Southampton Buildings, London.

SCREENS.—No. 15,022. Improvements in half-tone screens. William Charles Masser and William Hudson, 18, Southampton Buildings, London.

# FORTHCOMING EXHIBITIONS.

ember 11 to October 24.—Photographic Salon. Entries close August 31. Sec., Reginald Craigie, 5A, Pall Mall East, London, S.W.

ember 17 to October 24.—Royal Photographic Society. Entries close September 1. Sec., J. McIntosh, 66, Russell Square, London, W.C.

ember, 1908, to January, 1909.—Kiew International Photographic. Sec., S. T. Horovitz, Technical Society, Kreshtchatik, 10, Kiew, Russia.

1909.

ary 6 to 27.—Northern Photographic (Manchester). Entries close December 11, 1908. Sec., S. L. Couthurst, Broad Oak Road, Worsley, Manchester.

## Patent News.

*process patents—applications and specifications—are treated in the Mechanical Notes."*

the following applications for Patents have been received between July 13 and 18:—

**PLATE-HOLDERS.**—No. 14,827. Improvements in or relating to photographic plate-holders and the like. Kodak Ltd., Chancery Lane Station Chambers, London.

**PLATES.**—No. 14,828. Improvements in or relating to photographic cameras. Kodak Ltd., Chancery Lane Station Chambers, London.

**PHOTOGRAPHS.**—No. 14,837. Improvements in and relating to apparatus for taking or reproducing animated pictures. Louis Huet, 53, Chancery Lane, London.

**PHOTOGRAPHY.**—No. 15,050. Improvements in or relating to the photographic reproduction of colours. Edmond Charles Alain Caille, Norfolk House, Norfolk Street, Strand, London.

**VIEWING APPARATUS.**—No. 15,188. Improved means or apparatus whereby objects can be sighted or photographed from submarine or other situations. The Improved Periscope, Ltd., and Arthur Cyril Webb Aldis, 46, Lincoln's Inn Fields, London.

## COMPLETE SPECIFICATIONS ACCEPTED.

*Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**COLOUR-SCREEN-PLATES.**—No. 28,406, 1907. A feature of the present invention is the employment, in the manufacture of the polychromic colour-screen, of a printing or exposure screen composed of lines or other small elements of graduated opacity: that is, the lines are not made merely quite black and quite clear, but in addition to black lines and clear lines each set of the series forming the plate contains a semi-opaque line. Another feature of the invention is that the colloid film or coating which, as is after described, is differentially stained after exposure on the printing screen, is a single film or coating, and is not made up either by super-imposing separately made and stained or by producing separate strips of film side by side upon the plate. A colour-screen according to the invention is made from a single sensitised colloid film by one printing operation, followed by differential staining, and it is preferred to commence operations with a film deeply stained with one of the colours.

The following is a description of one method of carrying out the invention assuming it to be applied to a glass plate: The plate is treated with a solution of gelatine, fish glue, albumen, or other material containing a strong solution of a blue dye—for example, Prussian blue. This film or coating is sensitised, say by the addition of bichromate to the solution, or by the immersion of the plate in bichromate solution after coating. The plate thus coated is exposed to light, preferably daylight or the light of an electric

arc, beneath a printing screen of graduated opacity, and conveniently consisting of a number of sets of lines, each set comprising a black or opaque line, a semi-opaque line, and a clear line. This printing screen may be made in any convenient way; for instance, by photographic means from a ruled screen which has black lines of twice the width of the clear spaces or lines, this ruled screen being printed in two operations with a shift equal to the width of one line between the two printing positions.

The exposures in these two printing operations are of different duration to produce in one case a very dense or black line, and in the other a semi-opaque or grey line. The duration of the exposures is adjusted so that the density of the lines is such as to be suitable for the end in view.

After printing beneath the screen of graduated opacity, the plate is washed until the blue dye is completely washed out of the lines which have been protected by the black line in the printing screen, and partially washed out of the lines which have been partially protected. The result is that the coating bears a number of sets of lines, one of each set being strongly blue, another—the partially washed-out one—a blue green, whilst the third line is clear.

The plate is now soaked for a sufficient time in a yellow dye of such a nature that it will soak only into soft gelatine, dyes of this description being well known. As a result, the blue line, which consists of hardened gelatine, remains blue, the blue-green, partially soft line becomes pure green owing to the addition of the yellow, and the clear line becomes strongly yellow.

The plate is then soaked in a solution of a deep red dye, such as carmine. This dye penetrates only into the soft gelatine or yellow line and turns it into scarlet. Thus the screen finally comprises sets of three lines in juxtaposition, the lines being respectively scarlet, green, and blue. The lines can, of course, be of any required fineness, the degree of fineness being governed by that of the original ruled screen.

On coating the colour-screen thus made with an emulsion which is rendered panchromatic, the plate can be used for direct photography in colours in the manner now well known.

Although it is preferred to commence operations with a film deeply stained with one of the colours, yet the invention may be carried out by performing all the staining operations after the printing of the sensitised colloid film. In such a case the first staining would be by a dye that only stains hard gelatine—for example, a chrome mordant dye. This would stain the fully exposed line and partially stain the medium line, but would wash completely out from the soft line. The two subsequent staining operations could be carried out in the manner previously described.

Again, by selecting suitable dyes, the staining operation may commence with a dye which stains only soft gelatine, and may end with one such as a chrome mordant dye that acts only upon the hard gelatine.

It will be understood that the improved colour-screen, like others of the same general type, need not necessarily be in the form of a coating on the plate beneath the emulsion, but may be used as a separate screen.

The claims are:—

1. In the manufacture of a colour-screen the employment of a printing screen composed of lines or other small elements of graduated opacity.

2. In the manufacture of a colour-screen the employment of a printing screen composed of sets of lines or other small elements, one element in each set being black or opaque, one semi-opaque and one clear.

3. A colour-screen made by differentially staining a single sensitised colloid film or coating.

4. A colour-screen made from a single sensitised colloid film by one printing operation followed by differential staining.

5. A colour-screen made by exposing a stained sensitised film or coating beneath a printing screen washing out the dye from the parts not acted upon by the light and then again staining.

6. A colour-screen made by differentially staining a single sensitised colloid film or coating previously exposed to the action of light under a printing screen composed of lines or other small elements of graduated opacity.

7. The process of making a colour-screen for direct colour photography as described. Charles Edward Kenneth Mees and

Wratten and Wainwright, Ltd., 76 and 78, Canterbury Road, Croydon, Surrey.

**COLOURING PHOTOGRAPHS.**—No. 15,249, 1907. The invention relates to a method of colouring photographs or prints on paper or other materials which have not been previously rendered transparent (but, if necessary, impermeable to the medium employed) by the production on their surface of a film of coloured wax, solid paraffin or other transparent substance applied so as not to affect or impregnate the photograph, but to be retained on the surface. This is done as follows:—If the surface of the photograph or print be not already non-absorbent it must be rendered so by being coated with a strong solution of gelatine and squeegeed to a fairly coarse piece of ground glass. It must, if non-absorbent, be also rendered matt, if not already of that surface, by any convenient method.

Various methods of forming the film of coloured wax may be employed, separately or in combination, as follows:—The colouring matter mixed with wax, solid paraffin, or other similar substances, may be dissolved in chloroform, benzine, benzole, ether, turpentine, petrol, spirit, or other volatile or essential oils, and painted on the impermeable photograph or print. Or the wax may be melted and the colouring matter added thereto; or the photograph or print may be coated lightly with wax, the colouring matter applied to it in powder and subsequently fixed by melting; or all these methods may be applied in sequence; or the photograph may be stumped with powdered colour and fixed by spraying a wax solution over it. In any case, it is necessary to fix and blend the hues by subsequently warming the photograph or print on a metal plate or other hot surface and dabbing with a badger or other softener, as in oil painting.

As one example of the process applied to a platinum print the details of working are as follows:—The print is first painted over with a strong solution of pure, hard, white gelatine; then squeegeed on to a piece of fairly coarse ground glass previously wiped over with a little white wax dissolved in benzole. When dry, it strips off with an impermeable matt surface. Then some hard, white wax or solid paraffin is rubbed up in turpentine and the powdered or other transparent colour added till it is strong enough for the general tint of the complexion; say yellow ochre with a little Venetian red or rose madder. When that is nearly or quite dry, which soon occurs if it be placed on a warm metal plate, the shadows are tinted and strengthened with a little light red and blue and the lips and cheeks are touched up with carmine and vermilion; the reflected lights receive a warmer tint, the hair is coloured with any suitable browns or yellows; or, if black, with blue in the lights and blue and lake in the shadows, and the background is painted in. Everywhere, of course, the original colour of the monochrome, in this case preferably sepia-toned, has to be reckoned with and allowed for. Then the whole is allowed to dry and again placed on the warm plate and a badger or other softener is dabbed in the melted hues till all are blended together and any smeary appearance has gone. Finally a little powdered colour, Veronese green in the light shadows, rose madder on the cheeks and lips, etc., where required, is dusted on with a brush and fixed by again melting the wax. The result is a very durable picture which will stand gentle handling, and may be further protected by mastic or other varnish.

The special features of the process consist in its combination of the properties of water, oil, and pastel painting. The dissolved wax and colour can be laid on in broad washes as a water-colour; when dry it can be softened by heat, strong touches added, and then be softened and worked up like a recently laid-in oil painting; or colour in powder may be applied like pastel and fixed by heat, and all this in no way affects the underlying photograph or print, which is quite unaffected, and can be recovered at any time by cleaning off the waxen film with a solvent, when the portrait will be found uninjured if the gelatine protecting film be everywhere, as it should be, impermeable. Moreover, the drawing everywhere shows through the transparent film of wax, etc. This process differs from other processes of colouring photographs or prints in that a coloured waxen film is produced on the front surface of the photograph, which film is matt and yet transparent, and accords well with the untreated portions (e.g., white high-lights) and even allows them to remain unpainted without appearing incongruous.

It is obviously quite apart from all processes which involve conversion of the print or photograph into a transparency and application of oil or other paint to the back of the photograph print or its being mounted, after being made transparent a painted, on opal or other glass as a reflecting surface behind William James Townsend Barker, 304, Wandsworth Bridge Road, Fulham, London, S.W.

**TRIPOD HEADS.**—No. 19,391, 1907. The purpose of the invention is to enable the camera to be turned in one and the same plane in every direction in a horizontal plane, without turning the tripod or loosening the camera simultaneously. The drawings give form of construction of the invention. Fig. 1 is a longitudinal section of the novelty, fig. 2 a partial longitudinal section, fig. 3 a top-view of fig. 2. The head ends in a hollow cylinder threadless externally at the upper end, which is provided with slits. In this cylinder a pin is arranged which is fixed at its lower end to a screw c, which lifts or lowers the pin according to the direction in which it is turned. At its upper end it bears a conical enlargement, which spreads open the cylinder segments when the pin is lowered by means of the turning of the screw and presses

Fig. 1.

Fig. 3.

the cylinder against the wall of the nut with which the camera usually is provided.

In order to fix the camera it must be put on to the cylinder c, screw c is screwed down by means of the protruding handle G and G<sup>1</sup>, whereby the pin a is lowered and the enlargement presses the segments against the walls of the nut on the camera, and in this manner the camera is quickly fastened. By turning the screw the other way the segments spring back to their former position and the camera is released again. It has been found advisable to be able to regulate the position of the pin. The c of the screw is therefore bored at different places in order to receive the arms of the levers G and G<sup>1</sup> whereby the regulation of the necessary lowering is obtained. It has further been found advisable to have the head detachable from the stand. In consequence of the spreading parts, forming part of the head, having a larger diameter than the screw, it is not possible to provide the head itself with such a screw, and therefore the head is provided with a plate d. Gustav Geiger, 16, Maximiliansplatz, Munich, Germany.

**THREE-COLOUR PROJECTION.**—No. 15,726, 1907. The invention relates to systems of two or three-colour photography or projection with one lens, or with two or three, and describes the form and use of "prismoids," which are used as indicated in the two following claims:—

1. An apparatus in which three photographic records, placed one plane, by the aid of three lenses, two prismoids, compensating refracting material and artificial light, are projected in such a manner that the three part pictures will be united into one picture, if colour screens are interposed, the result will be a picture in natural colours.

2. An apparatus in which three photographic records, placed one plane, by the aid of one lens, two prismoids, compensating refracting material and artificial light are projected in such a manner that the three part pictures will be united into one picture, and colour screens are interposed the result will be a picture in natural colours.

WARREN.—No. 303,892. Photographic papers. Geo. Nelson, Dale and Co., Ltd., Emscote Mills, Wharf Street, Warwick, manufacturers of gelatine. June 13, 1908.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Thin Metal Slides and Thick Plates.

SOME other readers (writes a correspondent to "Photography and Focus" for July 28) may have had the same difficulty when using thin metal dark slides that I have met with, and have had the ill-luck to buy a box of plates a shade too thick. Although the makers of the dark slides appear to allow for thick plates, these do not go into the rebate at the top of the slides as easily as thin plates do. This is the case because the spring in the bottom rebate that pushes the plate up to the top, is hardly strong enough when the plate itself is a tight fit, and is pushed by the spring behind.

I have overcome this little trouble thus:—Part of a strip of black paper, such as that used with roll films, from half to three-quarters of an inch wide, and about four inches long, is placed under the plate at the bottom end before pressing the plate on to the spring, a piece of the black paper, about two inches long, being left out. This may be used as a handle to assist the bottom spring to lift the edge of the plate into the top rebate. The paper strip can be drawn out quite easily when the plate is in position.

### Sympathetic Treatment in Portraiture.

Sometimes one sitter will afford varying opportunities (writes Mr. A. F. Hirschfeld in "The Amateur Photographer and Photographic News" for July 28), for many varying effects of lighting and posing. Taking only one of the factors into account, there are many experiments that may be made in unconventional and unusual methods of lighting. Even in an ordinary room and with no special appliances there is great scope for this sort of thing. From among this great variety of methods it is most important to choose always those that are suitable for the type of sitter and in harmony with that sitter's characteristics.

Broadly speaking, there are to be considered, first of all, the characteristics of sex.

A lady's portrait, for instance, usually calls for delicate treatment: a light background, soft lighting, with no heavy shadows, and final printing on a smooth paper; whereas a dark background and a stronger, more dramatic scheme of lighting would be quite appropriate for a strong masculine face.

The aim in lighting and posing should be to emphasise special characteristics of the sitter, so that for ordinary sitters with no striking characteristics ordinary lighting is most suitable.

It does not necessarily follow that a sitter for whom an unusual method of treatment is suitable can be treated only in an unconventional way; ordinary lightings and simple poses can, of course, be adopted with these sitters, but the unconventional and unusual should be avoided with such sitters as are obviously unsuited for such methods of treatment.

Those who always bear in mind the importance of sympathetic treatment throughout the whole of the operation will find it of incalculable benefit, whatever branch of photographic work they may be engaged in. It is so easy to spoil the effect of an otherwise successful photograph by some slight mistake that might easily have been avoided.

## New Books.

"The Study of Stellar Evolution." By George Ellery Hale. London: W. Wesley and Son. Chicago: University of Chicago Press. 10s. 6d.

This handsome volume explains in a popular way how the life histories of the sun and stars are investigated. A brief historical sketch, in which the general purposes and methods of astrophysical research are outlined, is followed by several chapters on the sun, the only star that is near enough the earth to be studied in detail. An account of the spectroheliograph, which gives pictures of the sun, showing the "flocculi"—invisible clouds of calcium or iron vapour, or of hydrogen gas—introduces a series of chapters describing recent

methods of solar and stellar research developed at the Yerkes Mount Wilson observatories. A description of the organisation and construction of these observatories, one of them following conventional lines, the other representing many departures from tradition, serve to acquaint the reader with some of the practical problems encountered in astrophysical research. A study of sun-spots, showing how some of their phenomena may be imitated in the laboratory, and explaining their relationship to red stars, leads to the general question of stellar development. Succeeding chapters contain Laplace's original account of the nebular hypothesis, accompanied by the critical observations which have led to its downfall, and outlines of meteoritic and planetary hypotheses of Lockyer and Chamberlain. These serve to illustrate current speculations as to stellar origins, and indicate the nature of the observations required to test them. The most powerful telescope that will be available for this purpose in the near future is a sixty-inch reflector of the Mount Wilson Observatory. Most of the optical and mechanical work on this instrument has been done at the observatory instrument shop in Pasadena. An explanation is given of the processes employed in grinding, polishing, and figuring a great mirror, as these seem to be of special interest to observatory visitors. The book concludes with a discussion of the possibilities of new instruments and a chapter on the important work that can be done by amateurs with simple and inexpensive apparatus. One hundred and four half-tone plates, made from the best astronomical negatives, place before the reader the most recent results of celestial photography in most of its phases.

PRACTICAL TELEPHOTOGRAPHY—No. 90 of the Photo-Minia (Dawbarn and Ward, 6d.), deals with the later developments of telephoto lens, in practical telephotography for both technical and pictorial purposes. The text plainly conveys the arithmetic of the subject, has many hints on necessary precautions, and includes a number of first-rate examples of telephoto work.

## New Materials, &c.

"CRITERION" COURT SIZE POSTCARDS.—The Birmingham Photographic Co., Ltd., Stechford, send us samples of P.O.P., bronzed and gaslight postcards, which they supply of the statutory size in all varieties of these deservedly popular printing paper. The company also reminds us that the quarter and half-plate size of any of their printing papers can be supplied of postcard thickness thus giving Criterion users the facility of preparing photographs of a kind which require no mounting.

NEW "TABLOID" PHOTOGRAPHIC OUTFIT.—The marked success which has attended the issue of the "Tabloid" Photographic Outfit has led to the introduction of a further range. The new outfit includes the same quantity and selection of chemicals as the original case, but in slightly smaller space. The cases are prepared in red, royal blue, and bright scarlet enamelled metal. Their special attractive appearance is a useful selling feature, as they materially brighten up a window display and impel attention. Chemists and photographic dealers who wish to secure success should place their orders at once. The standard contents are: One regular package each of "Tabloid" Metol-Quinol Developer, "Tabloid" Pyro Developer, "Tabloid" Combined Toner and Fixer, "Tabloid" Hypo, "Tabloid" Potassium Bromide.

THE WALTHAMSTOW PHOTOGRAPHIC SOCIETY have enlisted the operation of the Urban District Council in an exhibition of photography to be given early next year, and the Library Committee have been instructed to make the necessary arrangements.

M. HENRI QUENTIN, editor of our Paris contemporary, "Photographie des Couleurs," will have the sympathy of many who have been helped by his courtesy and kindness, in the death of his infant son on the 24th inst.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, AUGUST 1.

London Photo Art Club. Excursion to Stonehaven.  
Ed Stereoscopic Society. "Outdoor Night Photography." S. W. Shore.  
h Suburban Photographic Society. Excursion to Gravesend and Cobham.  
W. C. Chaffey.

SUNDAY, AUGUST 2.

Ed Stereoscopic Society. Excursion to Burnham Beeches and Surroundings

MONDAY, AUGUST 3.

h Middlesex Photographic Society. Outing to Ware.

WEDNESDAY, AUGUST 5.

h Middlesex Photographic Society. Lantern Slide Competition.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Country  
ers who are visiting town are reminded that the weekly meetings  
the L. and P. go on all the year round, and visitors are always  
comed at the meeting house, the Apple Tree and Mitre, Cursor  
et, just off Chancery Lane, on Thursday evenings at eight  
ock. During the summer months, instead of a formal programme  
evening is devoted to any point that may have caused trouble to  
ember or visitor and there is no lack of subjects for discussion.  
or instance, on the 16th inst., in the course of debate, Mr.  
shwater said that he had found, with regard to old prints, that  
se which had been toned to a brown colour kept well, much better  
n those carried further to a purple. Mr. Haddon said that the  
sence of two metals meant an electrolytic action, and that if you  
irely remove the silver you get an image in gold, such an image,  
fact, as that obtained when the silver image has faded to the  
urless salt. Mr. Greenwood asked for a remedy when the print  
ks to the negative. Mr. Rapsun suggested soaking plate and  
er in hypo, and then removing the print, and if any stain showed  
lf to remove it with cyanide of potassium. It was thought  
ever, that such a course would remove the image as well, and t  
it would be better to soak the paper off in water and then fix  
negative.

s to dark-room lamps, a member asked if acetylene lamps could  
used instead of paraffin, as with the former he could get more  
t. It was, however, pointed out that the quantity of light  
the dark-room must always be subservient to safety. Mr.  
ldon thought that the chief objection to paraffin lamps was  
to the insufficient ventilation at the top of the lamp, and that  
could be remedied by a longer chimney, thus creating better  
ght.

was remarked that people sought for a fabric which was safe  
he largest light behind it, instead of a fabric which would allow  
to see well with a small light.

simple question as to the origin of the word "Ozobrome" by  
Dawson raised a most interesting discussion, which was not  
shed at closing time. Ozobrome owes its name to the idea that  
action on the pigmented paper was due to ozone, and although,  
was explained, this idea was quite erroneous, the name has been  
ined. Several members present had had much to do with the  
ufacture of ozone, and clearly showed that although it was of  
t service in chemical manufactures, it should only be handled  
those with perfect knowledge of its dangerous properties.

## Commercial & Legal Intelligence.

LEGAL NOTICES.—A first and final dividend of 10s. in the £ is  
be paid on July 31 at the Official Receiver's office, Great  
msby, in the bankrupt estate of Charles George Sinclair, photo-  
ther, of 264, Victoria Street, Great Grimsby. The receiving  
r was made in 1891.

the trustee has been released in the matter of John Edward  
es, photographer, of 48 and 50, Hermit Road, Canning Town,  
don, against whom a receiving order was made in 1906.

The Exeter Official Receiver has been released from the trustee-  
ship in the bankruptcy of William John Wilkinson, photographer  
and picture-frame maker, of 101, Union Street, Torquay, Devon-  
shire. The receiving order was made in January, 1907.

A first and final dividend of 3s. 6d. in the £ is to be paid in the  
bankrupt estate of Alfred Ernest Edward Clay Poole, photographer,  
of 9, The Crescent, and Midland Studio, Northumberland Street,  
Morecambe, Lancs.

The trustee has been released in the bankrupt estate of Harry  
Chapman Whiteley, 17, Quay Street, Huddersfield, and Ernest  
Crossley, 127, Leeds Road North, Huddersfield, trading in partner-  
ship at Leeds Road North as the Novelty Animated Picture Com-  
pany, cinematograph and lantern entertainers.

A CAPTAIN'S BANKRUPTCY.—At the final examination of Captain  
P. B. Hope, whose affairs have already been reported in the "B.J.,"  
the Registrar of the Bankruptcy Court granted a discharge,  
suspended for the minimum period of two years.

## News and Notes.

PROFESSOR RAPHAEL MELDOLA, F.R.S., has been elected President  
of the Society of Chemical Industry in succession to Sir Boverton  
Redwood.

L.C.C. AND PHOTOGRAPHY.—Some time ago the London County  
Council decided that, as an experiment for one year, the Council's  
photographic work should be done in the chemical and gas-testing  
department. The attention of the Local Government, Records, and  
Museums Committee has now been drawn to the fact that it will  
be necessary to make fresh arrangements to obtain copies of photo-  
graphs for purposes of record. Under the arrangement by which  
all photographs required were taken by a firm of photographers, it  
was considered necessary for a copy, in addition to those required  
for the purpose of the service affected, to be printed for the use  
of the chemist so that he might be in a position to certify as to  
the quality of the photograph. This copy was subsequently placed  
in the Council's library for purposes of record. Under the new  
arrangement, no special copy is necessary for certification purposes,  
and consequently the library collection of photographs is incomplete.  
The Committee is of opinion that, for purposes of reference, it is  
desirable that there should be a set of the more interesting and  
useful photographs ordered by the Council. During the last two  
years the number of photographs ordered by the Council has  
averaged 850 a year. The Committee has resolved that photographs  
be provided for purposes of record at an estimated cost of £65  
a year.

"URBANORA" AT THE PALACE THEATRE.—Monday next will wit-  
ness the advent at the Palace Theatre of the "Urbanora" ani-  
mated pictures, and Mr. Charles Urban may safely be relied upon  
to see that the exhibit well befits the importance of the occasion.  
His six new subjects—none of which has yet been seen by the  
public—will, primarily, include the latest scenes of the two great  
sporting events of the moment, Goodwood and Henley of 1908.  
Two important "travel" series will be "From Quebec to Niagara,"  
via St. Lawrence and the Thousand Islands, and "A Run on the  
Rhodesian Railway," from Untali to Beira, traversing the famed  
Amatonga Forest and encountering ground game of all descrip-  
tions, including elands, wild goats, cattle, baboons, etc. Another  
remarkable and an exclusively Urban subject, and one which will  
delight students of ornithology, will be the set of pictures illus-  
trating the "Haunts and Habits of Wild Birds." Specially taken  
by the famous naturalists, Messrs. Richard and Cherry Kearton,  
these films will furnish the spectator in ten minutes with optical  
information based upon the assiduous watching and waiting of  
many months.

MANCHESTER MUNICIPAL SCHOOL OF TECHNOLOGY.—At the examina-  
tions held by the City and Guilds of London Institute in technol-  
ogical subjects, the students at the Manchester Municipal Technical  
School secured thirty-one special awards in the shape of twenty  
bronze and eleven silver medals, together with money prizes to the  
value of £55 10s. Among these the following were by students  
in the Photography and Printing Crafts Department directed by

Mr. Charles W. Gamble:—Stelfox, Herbert Clifford: Photography (photo-mechanical processes), 2nd ordinary, £1 (Salters'), and bronze medal; Hallam, Edwin Walter: Bookbinding (forwarding), 1st honours, £2 (Skinners'), and silver medal; Bailey, Tom: Typography (press and machine work), 1st ordinary, £2 and bronze medal; Hanley, John Wm.: Lithography, 2nd ordinary, £1 (Cordwainers'), and bronze medal.

## Correspondence.

- \**We do not undertake responsibility for the opinions expressed by our correspondents.*

### THE FRAUDULENT SUBSTITUTION OF BROMIDES FOR PLATINOTYPES.

To the Editors.

Gentlemen,—In your issue of July 3 a correspondent signing himself "A Dabbler in Photography" states that he paid for platino-type photographs and received bromides instead. We shall be pleased in the interests of the public, in any similar case, where any one has been so defrauded, to employ counsel and pay all the costs of the prosecution, provided that we are satisfied with the evidence that a fraud has been attempted. Many unscrupulous photographers are guilty of this mean and contemptible imposture, to the injury of those who are doing an honest business, and we mean to protect our customers against such unfair and dishonest competition.—Yours truly,

THE PLATINOTYPE CO.

(E. J. Humphrey.)

22, Bloomsbury Street, New Oxford Street.  
London, W. C., July 25, 1908.

### WHEREIN ANASTIGMAT EXCELS R.R.

To the Editors.

Gentlemen,—In your current issue is a capital article on "Some Photographic Fallacies," by Mr. A. Lockett, in which he speaks of "much hazy inexactness of statement" has been made about the anastigmat lens. Now, while I am quite willing to believe that this form of lens is the crowning triumph of the optician, and that it will do better than the rectilinear, I should be personally obliged by being told in plain words, free from technicalities, what are the many reserve qualities and advantages possessed by the anastigmat to which the rectilinear cannot lay claim? I am about buying a new lens, and I do not mind the few extra pounds the new form will cost if I can understand exactly in what way my work is to benefit thereby, but, being an uneducated man, I cannot grip the science of optics in its most elemental form.—I remain, yours truly,

JAMES THOMPSON.

Chippenhams, July 25, 1908.

[The three chief respects in which the anastigmat lens is superior to the old type of rapid rectilinear are: (1) Larger working aperture; (2) greater covering power; and (3) finer definition. The first means the full exposure of plates which otherwise would be underexposed; the second means that a lens of focal length suitable for, say, half-plate, will cover a whole or larger plate, or will permit of great rise of front when a half-plate is being used. The third property means that negatives will give sharper enlargements.—Eds., "B.J."]

### UNFRAMED PRINTS FOR EXHIBITIONS.

To the Editors.

Gentlemen,—May I explain that in my suggestion re unframed prints for exhibitions I did not suggest, neither do I require, that secretaries should frame exhibits, but that exhibits *unframed* should be admissible, and *shown as such*.

May I point out that the Arts and Crafts, Plymouth, this year, is accepting unframed prints for competition and exhibition.

If suitably mounted on card with wide margins, prints should show to as good advantage as those framed.—Faithfully yours,  
St. Ives, Cornwall, July 25, 1908.

SYDNEY H. CARR.

## Answers to Correspondents

- \**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*
- \**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- \**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.*
- \**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street Strand, will undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, and two unmounted copies of each photograph must be sent with the photograph.*

### PHOTOGRAPHS REGISTERED:—

Mrs. Helena C. Sutherland, Cooleville, Clogheen, Cahir, Co. Tipperary. Photograph of Two Kittens. Photograph of Lion Cub.  
David Jones Davies, The Studio, Lampeter. Photograph of H.R.H. Prince Christian, Earl of Caerlaver, and Sir James Drummond, Bart.  
Albert Edward Stanley, 70, Stackpool Road, Bristol. Photograph of Suspension Bridge, Bristol.

AMERICAN LANTERN SLIDES.—I should be much obliged if you would give me the size of American lantern slides, and let me know if there is anything special in the fitting up and binding different from English slides.—SLIDES.

The most usual American size is 4 by 3½, though some make use the English quarter-plate—4½ by 3½. The size of picture about the same in each case. The Americans allow more room on the mask for inscription, etc.

OIL PROCESS.—I believe there is some method of producing paintings in colours (not one colour only). Is this the "process" which I see frequently mentioned in the "B.J.," or do you let me know the process or where to obtain same?—SUBSCRIBER.

There are, of course, the usual hand methods of working photograph in oil colours. The oil process, though just as a hand process, is not at all similar. It consists in forming almost invisible image, either by printing on a bichromated fine sheet or bleaching a bromide print or enlargement in a particular way (the bromoil process). The print in either case is brought out by applying a greasy pigment with a brush. The process is employed for pictorial purposes in monochrome. Colour effects so far produced have not been successful.

PICTORIAL PRESS, LEEDS.—If you will send your name and address for publication, we will answer your queries.

ELECTRIC LIGHT IN STUDIO.—Will you kindly let us know the following in "Answers to Correspondents" column of "B.J.": oblige! 1. What power of electric light is sufficient in studio with rapid portrait lens and rapid plates, and if equally as results can be got with ordinary lamps as with the electric? 2. Is it best to have lamps on a movable stand, the lamps hanging a foot or two from the floor upwards each side of subject? 3. Would wooden frame with white calico on answer as reflection if placed behind lamps?—SCOTT AND CO.

1. One or two enclosed arc lamps are usually sufficient. Most photographers do good work with only one. 2. Certainly. The usual plan is to mount the lamp on a stand, which can be moved about and on which the lamp can be easily raised and lowered. 3. Yes.

STUDIO CONSTRUCTION.—Can you refer me to any good book or publication upon modern methods in the planning and arrangement of studios?—A NEW READER.

The best book is "The Studio and Its Construction," by B. published by Marion and Co., 22-23, Soho Square, London, W. 1. We may also refer you to the series of articles on "Modern Note in the Design and Fitting of Photographic Premises."

Mr. Drinkwater Butt, which commenced in our issue of 27 last.

**PULP-BOARD.**—I am in possession of a large pulp-slab for which the surface of which has become white and greasy in appearance. I shall be glad if you can inform me the cause of this and how it may be removed, as it, of course, prevents the use of bromide paper obtaining the necessary high polish.—O.

It is clear from your description that the high polish the slab actually possessed has worn away by use. We cannot tell you how to improve the one you have. Possibly if you sent it to the makers they might repolish it, but that, with the carriage, etc., would probably come to nearly as much as a new slab.

**QUERIES.**—1. Is the lens on a "fixed focus" camera different from the one on a focussing instrument? 2. If the pointer on a focusing camera is set at "infinity" (also marked "25ft."), can I take sitters at 12ft. from the camera? 3. How is it that I can do so with a "fixed focus" instrument? 4. Would a negative taken at 12ft. by either camera yield enlargements suitable for the Illustrated Press? 5. How do pressmen know when moving stationary objects are in focus with such pocket cameras as "Palmos" or the "Goerz-Anschutz," which have only a frame finder, that remains the same irrespective of distance, or stop? 6. Where can I purchase the "Artists'" camera, described in the "B.J.," June 28, 1907?—ADVANCED AMATEUR.

The lens itself is not different; the difference lies in the focal length (short) and aperture (medium). 2. The images will not be as sharp as they should be. 3. Because the lens is fitted with a smaller stop. If you look at the table on page 10 of the "Almanac" you will see that in the case of a 5in. lens at  $f/8$ , the distance at and beyond which all objects are in sharp focus is secured on infinity is 26ft. With the stop, which is a common aperture for fixed-focus cameras, the distance is 13ft. 3. It depends on the degree of sharpness. You can tell whether the negative is sharp, or you can try experiment of making or purchasing an enlargement from the negative. 4. They have learnt to judge distances accurately and with the focussing scale set accordingly to, say, 12ft., 15ft., or 20ft. We advise you to study two books by Mr. Walter R. L. "Hand-Camera Photography" and "Advanced Hand-Camera Work"—both published by Messrs. Dawbarn and Ward each. 6. It is not on the market.

Most probably the negatives were not perfectly fixed. We cannot suggest any quite certain remedy, but you might try washing in potassium bichromate and hydrochloric acid (10 grs. bichromate and 20 minims acid to the ounce), and then wash well, by soaking in water acidulated with hydrochloric acid and in plain water. After washing, redevelop the films. It is fortunate that you used ammonia after the mercury, as this has doubt removed a good deal of the silver and so rendered retouching impossible.

**ROBERT.**—The only suggestion we can make is that you try Gertha dyes (Vanguard Co.). These are specially intended for staining gelatine, and can be obtained in a variety of colours. We will find no difficulty in using them.

**OWN LENSES.**—I have two lenses in good condition, with stops of different diameters. The one is marked "J. H. Dallmeyer, London, 1875"; the other, "Ross, London, 13725." Would you please tell me what lenses they are, and the value of same?—H. CASTELLO cannot possibly say what your lenses are from the numbers. The makers could do so, no doubt. Any lens by either maker will, however, always command a fair price. We should advise you to submit them to the makers and obtain full and reliable information.

**P.**—1. Messrs. Butcher and Sons, Camera House, St. Bride Street, E.C., supply a very similar, if not identical, paper. 2. The slip should be the actual size of a boat in order to be in line naturally with the figure, but as this would involve too great a breadth of the picture it is better to make a slip, say, 6ft. long. The question of the lens does not come in.

**ROBERTS.**—You are right in your views, but it is usual to have an assignment of the copyright in writing from the

sitter under such circumstances. However, the point, apart from this, is a very doubtful one, as to whether a sitter can exert any legal right in respect to the negatives. See the article on a similar case in our issue of June 5.

**JAN.**—As he was working entirely on commission we do not see that you can do anything, unless there was a written agreement to some such effect that he should engage in no other photographic business except that for you.

**SHOP FRONTS.**—I shall be glad of your assistance in a matter which has just cropped up in connection with an order I have received from a local firm to take photographs of three shops which they own in different parts of the town. The result of my first attempt has been that the shops across the way are almost as prominent in the negative as the place I wished to photograph. Is there any way of getting over this? It seems useless to try and retouch out the details of the opposite windows, as they are almost as strong as the others.—MINOR PRO.

The only effective way of dealing with the job is to erect a dark screen immediately behind the camera. It must be large enough to obstruct the view from the opposite buildings. If you cannot arrange for this to be done, either by erecting a special screen or by getting a tall van to halt in the required position, then the next best thing is to take the photograph by flashlight, screening the lamps so that no light from them is cast upon the opposite side of the street. We suppose that in making your attempt in daylight you have done all that was possible in choosing a time of day when the shop to be photographed was brightly lighted and the opposite houses in shadow.

**STUDIO QUERY.**—In some new premises which I am thinking of taking I can have a studio 6ft. by 19ft. of the single-slant pattern. The highest side is 11ft. and the lower 8ft. 6in.—that is the side-light is this amount. Do you think the studio is one in which I can really do satisfactory work in the way of portraits and small groups? What is the best arrangement of blinds, and what colour would you advise for the walls? You will see from the rough sketch herewith that I get practically a north light.—LANCS. AND YORKS.

The studio is certainly very narrow, but, with this exception, it should do well for all moderate size work. We should advise you to use top blinds on rollers and side curtains, as marked on the sketch, returned. A pale green or blue for both of these would answer well.

**"WHILE-YOU-WAIT" PORTRAITS.**—A firm has started here in premises which they have taken only for a week or two, and is running a business of the cheapest class, in which they sell a postcard of the sitter for sixpence, giving the card within a very short time—fifteen or twenty minutes. I suppose that this is done by printing from the wet negative, and as some of my customers who have spoken to me about it have doubted the possibility of doing this, I would be glad of your opinion as to it.—S. F. AND CO.

It is possible that the people are working from the wet negative, but in that case they have to give the negative, at any rate, some degree of washing. It is more likely they are using the dodge which has been published in our columns several times recently—viz., the use of a piece of thin celluloid, which is laid on the fixed negative after only a rinse of the latter from the hypo bath. The printing paper is then laid on the celluloid and the portrait printed off without any noticeable loss of sharpness, the thickness of the celluloid being so trifling.

**C. F. E.**—You need a lens of aperture at least  $f/4.5$ . You should consult the advertisements of lens makers in the current "Almanac."

**HYPH ELIMINATOR.**—Can you give me a simple formula for a solution which I can use for getting rid of hyph quickly from plates or prints? I have been running for some time past a cheap postcard line on the "while-you-wait" system. Though I can say that the complaints as to fading have been few, I would like to know if there is any rapid and cheap means of killing the hyph instead of washing out.—SIDE-STREET STUDIO.

Potassium permanganate, used with care, is as good an eliminator as you can adopt. You require a rather weak stock solution—say,  $\frac{1}{4}$  oz. of potass. permanganate in  $1\frac{1}{2}$  gallons of water. This solution is added to about twenty times its volume of water

(i.e., 1 oz. to 20 oz.), and the plate or print, which should first be rinsed for one minute under the tap, placed in it until the colour goes. The decolorised solution is then replaced by fresh (pink) solution, which is again replaced by fresh as long as the colour is discharged within, say, half a minute of pouring on. The whole process only lasts a minute or two.

**DEVELOPER FOR BROMIDE PAPER.**—We have been having trouble in getting a really strong good tone in bromide prints of late, and having been told that the best results are obtained with amidol, we should be glad to learn whether you think that is the case, and, if so, what formula for the amidol developer you would advise.—M. AND M.

We should hardly say that amidol is superior to any other developer, but it is certainly one of the best, particularly for black tones. The following is a proper formula:—

Amidol .....	50 grs.
Sodium sulphite .....	500 grs.
Potassium bromide.....	2 grs.
Water .....	20 oz.

The important point is to prepare the above fresh at the time of use. A stock solution of sulphite may be kept for a day or two, and used as required by addition of the amidol dry, but the finest results are produced by making up the whole developer fresh.

**MATT SEPIA PRINTS.**—A customer has shown me a number of prints of matt surface, not unlike toned bromides, which he says are made by a special process of his own, which is not, he says, a gelatine process. I suppose they must be sepia-toned bromides, but I should like to ask whether there is any such process at all answering to this description?—CHELTENHAM.

It is probable that the prints are by the Kallitype process, particulars of which you will find in the current "Almanac," pages 664 and 832. The process consists in the preparation of paper with a mixture of iron salts and silver nitrate, the partly printed-out image being developed with a mixed solution of borax and Rochelle salt. There is no secret about the process.

**OZOEASY.**—P.O.P. prints can be used, but a bromide is preferable.

**SANSAPARILL.**—We know of no process so suitable. If you will follow the instructions you cannot make a mistake.

**IWANDOTTE.**—What you want is a hot rolling press, supplied by any of the large dealers.

**F/11.**—The advantage of the lens, for its particular purpose, is that the definition is not critical.

**BLISTERS ON BROMIDE.**—Since coming here to take over a small business, I have had great trouble with bromide and gaslight prints as regards blisters, which in twelve years' previous use of these same papers I have never once experienced. I am told by a traveller of the paper firm that this is no fault of the paper, but is due to the softness of the water supply. Do you think this is likely to be the case, as, if so, I suppose the only remedy is to add some chemical to the washing waters to counteract the softening effect? I should like to know if this can be done.—BUBBLE.

Your experience is common among photographers who have to use a very soft supply of water. It is not always very marked when prints are quickly developed, fixed, and washed, but usually makes itself evident in sepia toning by the sulphide process. The remedy is to fix prints in an acid hardening bath. A formula is—

Water .....	64 oz.
Hypo .....	16 oz.
Soda sulphite .....	1 oz.

When dissolved, add—

Acetic acid, glacial .....	1½ oz.
Potash alum (dissolved in 5 oz. of water)...	1 oz.

This mixture should be only very slightly cloudy. In it prints feel leathery to the touch in about half a minute, but the bath should not be kept in use so long as to leave a print still soft one minute after immersion.

**INFRINGER.**—Like many another before you, you have been labouring under a delusion; you have no rights whatever in the photograph. You were paid in the first instance by the sitter, and all rights as to the reproduction of the photograph are vested in

him. The best thing you can do is to indite an apology for your offensive letter.

**WEST COUNTRY.**—1. Certainly not, in no circumstances. 2. make inquiries, but we never heard of anything of the kind.

**CAPE TOWNER.**—The firm has ceased to exist.

**LIGHT BANDS ON NEGATIVES.**—Can you explain the cause of one-third of every negative in a batch of about twelve lighter than the remainder? I enclose one of the negatives would say that all have a similar light band of the same and running the same way of the plate. All negatives treated as usual, and were first found to be as described or out of the washing tank.—L. M. S.

We think the only explanation is that the negatives were out of the fixing bath, and without rinsing placed in the tank, only partly covered by the water. The hypo in the exposure to the air will produce reduction, such as seen in negative you send.

**M. R. P. S.**—The Royal Photographic Society does not sanction the use of any such title.

**POSTCARD.**—The hand-fed machines, such as the Hana (Hofmann Ltd.), are decidedly the best.

**RETOUCHING.**—As our circular explained, it is useless to express opinion on retouching, except with prints taken from the negative before and after. If you seek an opinion of your work, you should be willing to take this very simple means to end being of value.

**FOCUSSED SCREEN.**—Requiring a ground glass screen of a degree of fineness, I have been trying (without success) to prepare or make one. The former I have failed in doing, and the latter of a large (10 by 8) screen I find a very tedious affair, the result also is not as fine as I should like. I came across a reference recently to a chemical method of preparing screens, should be much obliged for some directions as to the value of the process.—MICRO-RHOM.

The instructions appeared originally in the "B.J.P." March 30, 1906, and are briefly as follows: Three dry (extra-rapid) are immersed without any exposure to light in non-staining developer without bromide. Two are removed at the end of five minutes, fixed and washed in the usual way. The third is kept in the developer for twenty minutes, and the fourth is treated. No. 3 and No. 1 are then placed in a solution containing iodine 10 grs., dissolved in water, 10 grs.; potassium 100 grs. They are rinsed and bleached in weak ammonia, and dried. Plate No. 2 is immersed in a solution of bichromate, 10 grs.; hydrochloric acid, 5 grs.; water, rinsed, fixed for ten minutes, well washed, and dried. It forms a fairly dense iodide screen. No. 3 is a thin iodide and No. 2 a thin "chromium" screen. All are of value in grain.

THEIR ROYAL HIGHNESSES THE PRINCE AND PRINCESS OF WALES have honoured Messrs. Langier, Ltd., of 23A, Old Bond Street, with their Royal Warrants of Appointment.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received to the approval of the Publishers, and advertisements are accepted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

Chapman Jones has been appointed lecturer on photography in the Imperial College of Science and Technology. (P. 597.)  
Attention is drawn to the examinations in photography and photochemical work held annually by the City and Guilds of London Institute. The questions and practical exercises set at the last examination are given on page 605.

Lumière and Seyewetz have published an account of lengthy experiments on the precipitation and insolubilisation of gelatine. They show that many mineral and organic substances exert quite different actions on gelatine. (P. 602.)

J. Peat Millar gives a hint on the making of gaslight prints in the glass of the negative, and on the production of a border of gaslight or bromide print itself. (P. 601.)

Professor Namias recommends an acid solution of common salt or sodium chloride for treating over-printed P.O.P. prints. (P. 600.)  
Experiments which may be used by a photographer pressed for time when printing in P.O.P. are the subject of some notes on page 599.

A paper for the direct production in the camera of a portrait has been worked out by an American inventor. (P. 598.)  
A new method of colour photography suggested some nine years ago and revived in a current patent specification. (Pp. 598 and 607.)  
An American contemporary publishes a description of the method used by the well-known New York professional, W. M. Holman. (P. 604.)

Blackpool magistrates have warned travelling photographers that they must take out a licence under the Pedlars' Act. (P. 598.)

### "COLOUR PHOTOGRAPHY" SUPPLEMENT.

A full official description of the method of manufacture of the gular grain Lumière screen-plate is given on page 57.

Impel, in a recent paper before the French Photographic Congress, recommends the ingenious device of employing a phonograph in the dark-room to "talk" seconds whilst the Autochrome being carefully watched during development on the factor (P. 61.)

Each worker, M. Torchon, advises the sulphide toning of Autochrome plates after reversal in plate of re-development and fixation. (P. 60.)

A recent paper before the Royal Photographic Society, Dr. Kenneth Mees gave the arrangements of screens, reflectors, and lenses considered most advisable when constructing a one-colour camera for three-colour work. (P. 58.)

## EX CATHEDRA.

### Photography in the Imperial College of Science.

Although it has been known for a long time past that instruction in photography was to figure in the science and technology courses at the Imperial College of Science and Technology, that the necessary accommodation was under consideration, and that arrangements had been made as to the charge of the department, it is only quite recently that the official appointment of Mr. Chapman Jones as lecturer on photography in the Imperial College has been made. The department has, in fact, been undertaking its duties for some time past waiting the formal decision of the Governing Body. At present exigencies of space compel the department to almost limit itself to its primary object of giving such instruction to science students in the principles and practice of photography as shall enable them to make efficient use of photographic methods in their own callings. It is intended, however, that as further facilities are available the study of special branches of photography will be made possible, and that students will have the opportunity of carrying out research work in the department. At present, however, the size and equipment of the department are not much in excess of what is necessary for the instruction of the general student; in fact, for that purpose alone both might well be expanded.

\* \* \*

### Collections of Photographic Specimens.

One of the duties which the new photographic department of the Imperial College of Science and Technology is setting before itself is the assembling of specimens illustrating departures in photographic processes and certain methods of work. A considerable nucleus of such a collection has been already formed by Mr. Chapman Jones, but the willingness of the department to receive, as a gift or a loan, exhibits which are of educative value may well be brought before the notice of those whose possession of such objects is frequently a matter of little advantage to themselves and none at all to anybody else. Although not a public institution in the way that the British Museum is, the department is so situated that objects forming part of a collection such as this might be seen by any one who has any good reason for wishing to do so, and a loan or donation is thus of service even to a greater number than the students who will pass through the department.

\* \* \*

### The Work of Mr. G. R. Ballance.

It is good news to hear, in the "Photo Era," that Mr. G. R. Ballance, whose delightful photographs of Switzerland are familiar to most visitors, is this summer touring in the Tyrol and Black Forest with the object of producing

photographic souvenirs of these picturesque districts. Mr. Ballance started photography twelve years ago, when seeking a recovery of his health in outdoor pursuits, has pinned his faith to slow isochromatic plates and platinotype paper, and has made his work known throughout Europe. It is interesting to find that his photographic religion is a faith in the pure, "unfaked" photograph which is a faithful transcript of a beautiful scene before the camera. He writes:—"The modern, retouched, double printed, faked fuzzy-wuzzotypes seem to me like nothing in nature; and surely nature is beautiful enough without attempting any such doubtful improvements. I never exhibit, not valuing the opinion of judges who have never seen the subjects depicted, and who are, therefore, not in a position to say whether the lighting, tone, and subject are consistent. Recent much-admired photographs of Venice in a London fog, with steeples out of focus and English clouds printed in upside down, seem false to me, bad art, and a libel on Venice as I know it. It greatly amused me to send in to the London Salon a study of olive-trees printed through the back of glossy sepia platinum paper, producing a blotchy image of a dark, dirty, yellow, mud colour, the whole picture having not the slightest resemblance to anything on earth except, perhaps, broken firewood as might be seen through a jar of Thames water by a drunken man suffering from jaundice. The picture was, of course, accepted, and my only hope is that no one took it for a serious attempt on my part at depicting the beauties of an Italian olive grove, with the slate-gray, gnarled old trunks and the shimmery sunshine on the light foliage."

#### Positive Prints Direct in the Camera.

A specimen of a new process for producing a paper print by exposure in the camera has been sent to us by Mr. Chas. Dawson, of Holloway Hill, Godalming. It is the invention of a Mr. Pifer, of Cleveland, U.S.A., for whom Mr. Dawson, so he informs us, is acting in the matter of the disposal of the patents. We have no information as to whether the process involves the reversal of the primary negative image by some such process as is employed in the case of the Autochrome plate, or whether a direct reversal is produced in development. At any rate, the result which we have seen is an excellent print, closely resembling a collodio-chloride print, toned with platinum, and altogether too good for the "portrait-while-you-wait" class of work, for which such a process seems more suited than anything else, except perhaps certain special Press work, in which one print would suffice.

#### A "System" of Colour Photography.

The desirability of search by the Examiners beyond the limits of prior specifications is well instanced by a patent which figures in the "Patent News" on another page. There, it will be seen, protection is given to a process which, so far as taking the negative is concerned, is identical with one recommended, though not patented, so far as we are aware, by Mr. Friese-Greene in the year 1899. The idea, which was hailed by Mr. Hector Maclean but by no one else as a promising method, consisted in the rotation before the lens of the camera of a disc divided into three transparent sectors—red, green, and blue. This disc was rotated at the time of making the negative, and again before the lens of the lantern by which a transparency from the negative was projected. On the screen the result showed a certain dull red coloration of the shadows, due, it seemed, to the fact that the lights of the picture were white because illuminated by all three sectors, whilst the shadows assumed a red tint because protected from the blue and green rays and illuminated by red rays dispersed from the sector of that colour. That the present patentee should expect to make colour-prints from the

positive which he obtains in the way above described amazes us more than the original proposition.

#### Itinerant Photographers and the Pedlars Act.

We have once or twice heard of the interference on the part of the police with the photographers who get their business by house-to-house canvassing, ground that such trade comes within the Pedlars' Act. We must not be carried on except by those possessing a licence. While we should not identify one who obtains orders afterwards delivers his photographs in this house-to-house manner with the pedlar and his bundle of miscellaneous wares, we applaud rather than otherwise the action of the police, since it puts a check on the cadging methods of the itinerant photographic fraternity, of whose doings we constantly hear too much. Therefore we cannot be expected to quarrel with the Blackpool magistrates, who, according to a decision of Thursday in last week, have notified itinerant photographers that they will be expected to obtain a licence. This decision arose out of the sum of five travelling photographers, who were obtaining business by going from door to door. They were fined 5s. each and costs.

#### Rectilinear v. Anastigmat.

A correspondent last week wanted to be assured of the practical advantage of anastigmat lenses over rectilinears. A great many people seem to be equally uncertain whether the difference in cost is really worth incurring. The rectilinear is a very useful instrument if it is a good specimen, and there are many good rectilinears about, but no one who replaces the R.R. by an anastigmat is likely to regret the change. In our answer we gave three advantages large aperture, great covering power, fine definition. Many rectilinears will define very well indeed in the centre of the plate, for which reason we have often recommended their use for very long focus narrow angled work in preference to the exceedingly expensive very long focus anastigmats; but when used for ordinary angles of view the anastigmat will probably give as good definition in the corners of the plate as the R.R. does in the centre. If the results are compared, even only a few inches away from the centre of the plate, the superiority of the anastigmat will be manifest, and it is generally very surprising to the man accustomed to the R.R. The value of large apertures, of a size that is quite impossible with rectilinears, needs little comment, but is one other rather important point that should be borne in mind. When purchasing one of the high-priced anastigmats produced by the best makers we are buying an instrument that has been very thoroughly tested in all respects and proved to be up to a certain fairly high standard. On the other hand, when buying the cheaper R.R. of some make, or even the cheap form of anastigmat, we are getting or less purchasing a "pig in a poke." We may get an excellent lens or a very poor one, for it is obviously impossible that these cheap "lines" can be as carefully and minutely tested and adjusted as the high-priced instruments upon which the makers stake their reputation. Some of the old R.R. lenses by the big makers were tested with great care, and they form excellent bargains. But still they are very deficient compared with the anastigmats, the purchaser of which always gets full value for his money.

#### The Hardening of Gelatine.

On another page we give a very important article by the Messrs. L. and Seyewetz containing much information that sooner or later may prove to be of considerable practical value. These indefatigable scientists have a long series of researches on the effects upon gelatin

rious precipitants and hardening agents, and the net result seems to be that such agents may be divided into three classes. First, precipitants that throw down a material soluble in hot water, apparently of the same composition and possessing the same properties as the original gelatine. Second, precipitants that throw down insoluble in hot water, with different properties and composition differing from that of the original gelatine. Third, agents that render gelatine insoluble in hot water and do not throw down any precipitate. It will be seen from the tables that generally we use only for hardening purposes the agents that belong to the third class, such as the bromium salts and formalin. The precipitants in the second class include many of the substances used in photography, and though they do not all have the same effect on gelatine films as on gelatine in solution, nevertheless some of them have a very powerful hardening effect on a print. Some modern processes take advantage of these facts, and probably much more use will be made of them in the future. Presumably vanadium chloride should be in this class, though it is not mentioned. It does not appear that the peculiar properties of the precipitants of the first class can be made much use of at present, though many familiar photographic chemicals are included in the list. Perhaps, however, it may be possible later to turn them to some useful account. It will be noticed that some very familiar reagents, such as hydroquinone and pyro, appear in both the first and third classes. They throw down a soluble precipitate, but their oxidation products render gelatine insoluble and are retained or "fixed" by the print. On the other hand, the reagents in the second class do not give an insoluble precipitate are stated to have the common property of supplying oxygen, either directly or through the presence of water.

#### EXTREME MEASURES IN P.O.P. PRINTING.

The ordinary routine of P.O.P. printing has been the subject of so much written and verbal advice to the photographer that one can hardly think there is another word to say as to the procedure which may be adopted. Our object here, however, is not to make any recommendations of a general nature as to the toning and finishing of platinum-chloride prints, but to point to one or two matters which are of minor importance in the usual run of things, but may become of some real importance once in a while. As an example, the trade printer occasionally is asked to produce one print from each of a large batch of negatives at very short notice; that is to say, he may receive the negatives in the morning, and be required to put finished P.O.P.s in the post in the evening. In such circumstances it is not improbable that one or two prints of a large number may fall short of the average quality, through over- or under-printing. Such is very likely to be the case if the negatives vary much in quality, and a negative which prints quickly needing a considerable degree of over-printing compared with a strong, slow-printing negative. Thus it may easily happen that when the prints come from the toning bath one or two of them are distinctly too much on the dark side, while the others may be one or two which suffer in the other direction. Even supposing the light permits of fresh prints being taken, the delay in getting the whole job out of hand would deter the photographer from taking this step to get things right; but usually the waning daylight does not permit even of this being done. Therefore, if a method of after-treatment can be applied to the print, such as will be the most satisfactory in every way. As regards the reduction of over-printed proofs, we translate from another page a recent paper by Professor Namias, in

which he advises for the purpose a bath of salt and hydrochloric acid, with, if necessary, the addition of a little copper sulphate. While we have not tried the formula recommended in precisely its present form, we have employed a preparation of copper sulphate without, however, finding it better than, or as good as, other solutions. Some year or two ago we made a series of comparative tests of all the reducers advised for the reduction of P.O.P. prints, especially with reference to their absence of unfavourable action on the tone of the print and as well to the convenient adjustment of their strength when using them for prints which were greatly or only very slightly overdone. Of all the methods available there was none which we found so excellent for the purpose as a dilute form of the reducer worked out by Mr. Alexander Haddon, in which potassium ferricyanide is used in conjunction with ammonium sulphocyanide. The formula as then used, and given in the "Almanac" during the past few years, is as follows:—

10 per cent. ammonium sulphocyanide solution ...	5 ozs.
10 per cent. potassium ferricyanide solution .....	$\frac{1}{2}$ oz.
Water .....	24 ozs.

This mixture is made at the time of use—it will not keep—and may be compounded with less water than that here given if it is thought that the more dilute solution will be too long in its action. We would word the caution, however, that a slowly acting solution is preferable to one of more rapid performance as regards absence of action on the tone of the print. This solution, of course, is the well-known Farmer's reducer, with the hypo replaced by sulphocyanide. The latter acts equally well as a solvent of the silver ferrocyanide which is formed, and the solution is quite stainless and without the tendency to give "mealy" or "flannelly" prints which makes the mixture of hypo and ferricyanide quite unsuitable for the purpose. This weak Haddon reducer is employed after the print has been toned, fixed, and washed. It is not necessary to give a further washing beyond a minute or two in running water, which is a point in the favour of the reducer in comparison with the next best formula for the same purpose, namely, ammonium persulphate. This latter, while equally without prejudicial effect on the tone—in fact it improves the tone in the direction of a cold black—should be followed by re-fixing in hypo in order to make certain of the permanency of the print.

As regards the intensification of a print which has been accidentally under-printed, the remedy is not so satisfactory as that just described in the case of over-printing, but it will nevertheless be found that advantage can be taken of the usual mercury and ammonia process of intensification, the well-washed print being bleached in solution of mercury bichloride and darkened (after washing) in weak ammonia, say, 1 dram of the .880 ammonia in 10 ozs. of water.

Finally, there is an alternative which can be followed if the negatives are not abnormally dense—further prints can be taken by magnesium light and brought up to full density in an acid developer. Usually the combustion of 12 or 18 inches of magnesium ribbon at a distance of 3 or 4 inches from the negative will be sufficient to impress a developable image, which can be brought to full strength in a suitable developing solution. One of the best formula for this purpose is that of Dr. Wolseley Blacklock, made as follows:—

A.—Pyrogallie acid .....	32 grs.
Tartaric acid .....	32 grs.
Water .....	16 ozs.
B.—Potass. bichromate .....	1-16th gr.
Water.....	16 ozs.

The minute quantity of bichromate in the B solution is best introduced by making up a stock solution containing 10 grains in 10 ozs. of water, and adding  $\frac{1}{2}$  dram of this to 16 ozs. of water. Equal parts of A and B are mixed together to make the developer, which is used immediately. The prints are fixed in a bath containing hypo 1 oz., lead acetate 60 grs., in water 6 ozs., in which

the prints lose very little. The use of the magnesium conjunction with a developer such as this should place a worker in possession of duplicate prints of correct strength within five minutes. The tone given by the above form is not at all displeasing, but may, of course, be modified by passing the prints through the combined toning fixing baths or through the separate baths.

## TONING BATHS FOR OVER-PRINTED P.O.P. PRINTS

[In prescribing a formula for the recovery of over-printed P.O.P. prints, Professor Namias, in the following article from "Photographie des Couleurs," directs the use only of the everyday chemicals which every photographer has at hand or can purchase from the nearest chemist. In many circumstances the cheapest method is to make a second print, but there are times when the use of some such method has to be adopted at the risk of disappointing a customer or being late with a print which is urgently needed. We refer to the measures which may be taken on such occasions in an article on another page.—Eds. "B. J."]

BEFORE prescribing the means which can be taken in dealing with over-printed proofs, a word should be said in reference to the common assumption that it is possible to correct for excessive exposure to light when printing from a negative on a paper of the printing-out class. In point of fact, such correction is not possible after the over-exposure exceeds a certain limit. If we suppose that we are dealing with a negative which possesses three degrees of density, which we will designate by 1, 2, 3, those of minimum density, the clear portions of the negative, being denoted by 1, whilst the densest portions, the high-lights of the subject, are represented by 3. If a normal print is made from such a negative on print-out paper, we obtain three tones in the paper which are the converse of those in the negative, viz., 3, 2, 1. These tones are due to the decomposition of the silver salt and the formation of, say, metallic silver.\* We can assume that the quantity of silver will be proportional to the numbers 3, 2, 1. But this is so only for a certain degree of printing—i.e., up to the point where the maximum of the reducible silver salt is formed under the parts of the negative corresponding to density 1. Beyond this point the ratio 3:2:1 no longer holds good, since the intensity of the deposit of silver corresponding to the density of 1 of the negative remains constant (all possible silver salt having been decomposed), whilst the deposit is increased under densities 2 and 3. On continuing printing, a point is reached at which the darkening of the film under density 2 also reaches its maximum, and the only part where there is a lesser degree of deposit is under density 3.

If printing is pushed beyond this point, the print, on being fixed, shows as almost or quite identical two tones which ought to appear quite distinct. No method of reduction can be really effective in this case, since the silver deposit is the same in the two parts of the image, and, therefore, is reduced by the solution to the same lighter tone. This example does not exactly correspond with an actual print which may be made in ordinary work, but it serves to explain the differences which may result from the excessive printing, even after advantage has been taken of reducing solutions. In an ordinary negative there are  $n$  degrees of density. If the over-printing has not been too excessive, we still have in the print, if not  $n$  different tones (the darker tones easily become merged in one another), at any rate,  $n$  different states of decomposition of the silver salt. By submitting the print to a uniform process of reduction, the whole  $n$  tones are lowered, and a passable print obtained.

\* The image is not actually pure metallic silver, but the above will suffice in explaining the process.

But, when the exposure exceeds the limit corresponding to the maximum decomposition of the silver salt in the film, the gradation between the different states of decomposition corresponding with the different densities of the negative ceases to exist, and no bath whatever will restore the print to the state in which it was at the period of correct printing. The following, however, is the method which is most strongly recommended for the reduction of over-printed P.O.P. prints:—The prints are placed direct in the following bath:—

Common salt (sodium chloride) .....	100 gms.
Hydrochloric acid, commercial .....	20 ccs.
Water, enough to make .....	1,000 ccs.

The prints are left in this bath for from five to ten minutes, then given a rinse and transferred to a combined toning and fixing bath.

This treatment, however, will be found sufficient only in the case of prints which have not received a very great degree of over-printing. In the case of prints in which the printing has been carried on a good deal beyond the proper point, additional treatment is required. The reduction takes place to an extent about proportional to the quantity of copper sulphate added, but the action is most effective after the print has been through the combined toning and fixing bath. The action of the bath is very rapid, and it is well to make one or two preliminary trials in order to keep it in hand. The bath soon becomes exhausted and requires to be renewed with fresh additions of sulphate of copper. If the prints are to be separately toned and fixed, the following solution can be used up as a combined toning and reducing bath:—

Gold chloride, pure .....	$\frac{1}{2}$ gm.
Common salt (sodium chloride) .....	10 gms.
Hydrochloric acid, commercial .....	5 ccs.
Water, to make .....	1,000 ccs.

This bath tones and reduces the prints at one and the same time. If the resulting tone is not satisfactory, the print can be transferred to a normal toning bath of gold and acetate after it has reached the right degree of vigour in the bath given above. It is well to bear in mind, however, that even in the cases where the over-printing has not reached the limit pointed out above is not the easiest matter to obtain the same perfection of regularity of tones which are produced with prints which have been printed to the right point.

R. NAMIAS

## TWO PRINTING HINTS FOR THE PROFESSIONAL.

was, and that not so very long ago, when the use of development papers in the professional studio was confined to the making of enlargements. But the advent of "gaslight" paper brought a change, and a large proportion of professional photographers of the middle class now appear to be using this of paper for contact work to a considerable extent, if one judge from the contents of their showcases.

Though many amateurs find considerable difficulty in the use of gaslight papers, the professional seems to be particularly successful in their manipulation, and by the careful selection of negatives suited to the particular make of paper, some firms produced quite unique results, to which they have given special names. The production of a suitable negative is one of the chief factors tending to success and uniformity of results. Among the various makes of gaslight papers, one a little better than what would be termed an "average" negative

of bromide, gaslight papers requiring too prolonged an exposure when a number of prints are wanted.

This method is also a convenience to the worker who does a little in carbon printing, and, to save double transfer, exposes his plate with the glass side towards the lens, and who requires to turn out some prints on gaslight or bromide paper. He has only to place the negative the wrong way about in the printing frame, expose to light coming through the lens, as above, in order to obtain prints as sharp as he can want them, and at the same time get a soft result from his carbon negative. The result will be the same whether the light is daylight or artificial, and the time of exposure about the same as in enlarging.

If no enlarging apparatus is obtainable, the same result may be obtained by using any lamp with a lens in front of the light, which throws out a straight beam, such as is known as

No. 1.—Contact print from negative.

No. 2.—Reversed print from glass side of negative.

No. 3.—Print with sheet of glass between negative and paper.

is the best for the purpose. But it is not always possible to obtain exactly the kind of negative one wants, and, through a slight error in exposure, or development, or possibly both, a negative may be obtained which is just a little too "contrasty" to give the desired result in printing, and under such circumstances the following simple dodge has been found of use in improving the finished result.

Printing from a negative of the last-named type a much sharper and more pleasing result will be obtained if a piece of clear glass is placed between the negative and the print, and the exposure made with light coming through a

If the exposure were made in the ordinary way, the result would be softer, but the image would be blurred, and of no use for professional portraiture. The following is the best method of procedure. Take a piece of the most rapid paper obtainable, print it in an ordinary printing frame as usual, but with a piece of clear glass between the paper and the negative, and expose the required time by placing the frame on the easel of an enlarging camera so that a full play of light from the lens will fall on the negative, which must remain stationary during the exposure, the lens being uncapped and re-capped as in enlarging. The paper most suitable for this work is one of the slow varieties

of a "bull's-eye." The advantage consists in the light coming through a lens and travelling in a straight line.

There is another matter which has failed to receive as much attention as it deserves from those photographers who use gaslight papers, and that is utilising the paper as part of the mount. Some print the portrait in the centre of a sheet of paper larger than is required and leave the margin white, or, in some cases, merely put a plate-mark round the picture. To print a border of some kind round the portrait is only a matter of obtaining a suitable border negative with correct registration during the double exposures, but correct registration is not always easily got, and more paper may be needed than is advisable. Now, any one can vignette a portrait in the centre of a piece of paper, and can also cover the portion containing the portrait with a piece of black paper. The whole can then be placed, face down, on a sheet of clear glass in a printing frame, and the back put on without the slightest risk of shifting the position of the black paper. After exposure to the light, and development, the vignettted portrait would be in the centre surrounded by a plain black border, but, as black would rarely, if ever, be required, a better plan is to use a piece of ordinary white paper in place of the black (without water-mark, of

course), and expose through that, thus obtaining a border with a granular effect, varying according to the grain of the paper, and lighter or darker according to the exposure given, but having much the appearance of a "nature" paper selected to harmonise with the colour of the portrait. If desired to add further to the effect, lines, either broad or narrow, may be drawn on the paper, which, on development, will all show as soft white lines. It is always better when lines or other ornamentations are drawn on the white paper to fix the black paper in the centre of those lines with a guide mark at the edge to regulate the position of the printing paper.

By this means one can produce cards in a style entirely of own. They can, of course, be afterwards mounted on ordinary mounts, but a better style is to have the paper double size required, with the print mounted on the back half and other folded over in the form of a book or folder. Something of this kind, which is rather out of the common style, always command a better price than that which can be obtained everywhere, and even a homely snapshot can be made to be decidedly more picturesque if mounted in some such way as above described.

J. PEAT MILLAR.

## THE PRECIPITATION AND INSOLUBILISATION OF GELATINE.

CERTAIN substances added to solutions of gelatine give rise, as is well known, to precipitates, whilst others produce with these solutions, and without visible precipitation, compounds which cannot be again rendered liquid in hot water when they have once set. Hitherto the analogy between the various compounds which produce these changes has not been studied. Moreover, it was not known whether the gelatinous precipitates obtained with certain substances were composed simply of gelatine thrown out of its solution unchanged as regards its composition and properties,\* or whether we had to deal with substances having a composition and properties depending upon the substance employed.

The present series of experiments were made in order to ascertain the facts as to:—

1. The bodies which precipitate gelatine and the possible relations between them.
2. The composition of the precipitated gelatine.
3. The bodies which, without precipitating gelatine solutions, produce combinations with the latter which do not again become fluid once the jelly has been formed.
4. The possible relation of this last phenomenon and that of precipitation.

### Action of Mineral Bodies on Gelatine.

Additions were made to a 10 per cent. solution of gelatine of aqueous solution of a series of mineral salts selected from the carbonates, chlorides, bromides, iodides, sulphates, sulphites, hyposulphites, nitrates, nitrites, hypochlorites, chlorates, bromates, iodates, cyanides, sulphocyanides, phosphates, borates, arsenites, arsenates, silicates, chromates, molybdates, tungstates, vanadates, and ferro- and ferri-cyanides. The solutions were employed of strengths which differed with the different substances. The first trials were made with a 5 per cent. solution, and, if this did not work, successively increasing strengths up to 50 per cent. were used so far as the solubility of the salt permitted. The *modus operandi* consisted in pouring the solution into the gelatine solution, or *vice versa*. Among the great number of mineral bodies which were thus examined only the following were found to precipitate gelatine: Phospho-tungstic acid, or a mixture of phosphoric acid and sodium tungstate; phospho-molybdic acid, or a mixture of phosphoric acid and ammonium molybdate; chlorine water,

bromine water, ferric salts (with the exception of the tartrate and citrates and the double salts with these acids), manganese and vanadic salts, ceric and uranic salts, gold chloride, platinum chloride, mercuric salts, and potass. permanganate.

A certain number of salts, including the carbonates, phosphates, nitrates, sulphites, bi-sulphites, and hyposulphites of the alkali metals, precipitate gelatine only when the solution is of sufficient strength. This is the case with solutions of 15 per cent., the action increasing with solutions of greater strength. Among such salts are the following: Sodium carbonate, potass. carbonate, ammonium sulphate, sodium phosphate, potass. sulphate (the 10 per cent. saturated solution gives a slight precipitate), ammonium, sodium, and potassium nitrates, sodium sulphite, bi-sulphite, and hyposulphite.

Lastly, the salts of aluminium increase the viscosity of gelatine solution without producing a visible precipitate. It will thus be seen that all the mineral bodies which precipitate gelatine in dilute solution are oxidising agents. The converse of this statement does not hold good, there being a good number of mineral oxidising bodies (salts or acids) which do not precipitate gelatine solutions. The power of precipitation is therefore not a common property of the mineral oxidising bodies.

The substances which precipitate gelatine only if they are employed in highly concentrated solution are the carbonates, sulphates, sulphites, bi-sulphites, hyposulphites, and nitrates of the alkaline metals. This action differs from the preceding in the fact that the gelatine precipitated by the strong solution of an alkaline salt re-dissolves immediately on the addition of a sufficient quantity of water.

### The Action of Organic Compounds.

Only organic bodies soluble in water have been tried. Apart from certain liquid substances soluble in water, such as acetone and alcohols, in which it is well known that gelatine becomes insoluble, the organic bodies which appear to precipitate gelatine are as follows: Phenol, resorcin, orcin, hydroquinone, pyrocatechin, gallo-tannic acid, pyrogallie acid, para-nitrophenol, chlorophenol, picric acid, monochlor-hydroquinone (adurol), "acid R." (disulpho- $\beta$ -naphthol 2.3.6.), "acid S." (disulpho- $\beta$ -naphthol 2.6.8.), and "acid S." (monosulpho-naphthol 2.6). The naphthols, dioxynaphthalines, amines, and the amido-phenols do not precipitate gelatine solutions.

Among the organic compounds it is only the phenols or their products in which a nitro, halogen, or sulpho group has been substituted (in the acid state, but not the salts) which are able to produce precipitation. Phenols, slightly soluble in water such as the  $\alpha$  or  $\beta$  naphthol, as also the simple amines, basic or saline compounds of the latter class, do not precipitate gelatine. The same holds true with regard to the amido-phenols, which are very soluble in water.

\* Lüpke-Cramer has recently shown ("Zeitschrift für Chemie und Industrie der Colloide," 1907, Heft 12) that certain of these phenomena of the precipitation of gelatine by metallic salts, such as ferric chloride, take place at the same time as the hydrolysis of the salt employed, the oxide of which is thrown down in the colloidal state. There is thus produced the hydrosol of ferric hydrate which coagulates the gelatine to a reddish-brown jelly. This change of the ferric salt from hydrate into hydrosol appears to be identical with that which occurs when a weak solution of ferric chloride, containing no hydrochloric acid, is heated. Lüpke-Cramer has shown that the coagulation and insolubilisation of gelatine by ferric salts only takes place when the ferric oxide is thrown down in the colloidal state. The substances which break up the colloidal state of the oxide of iron also destroy the insolubility produced by the ferric acid.

ndently of the bodies which precipitate gelatine or its  
it is well to consider those which can be added to  
olutions without producing precipitation, but yet give

The mineral substances which give rise to the first class of precipitate are comparatively few, and are all alkaline salts with the exception of phosphotungstic acid, phosphomolybdic acid (or the equivalent mixtures above mentioned), and the mercuric salts. The mode of action of these compounds appears different from that of the alkaline salts, inasmuch as these

latter produce precipitation only in very strong solution, whilst phosphotungstic acid and the mercury salts act in weak solution. Moreover, gelatine precipitated by these substances does not dissolve in cold water, whilst in the case of the alkaline salts the gelatine re-dissolves on simple addition of cold water.

Organic substances which produce precipitates soluble in warm water appear to belong all to the class of phenols or substituted phenols, namely, phenol, resorcin, hydroquinone, pyrocatechin, orcin, pyrogalllic acid, monochlor-hydroquinone, picric acid, chlorophenol, naphthol-sulphonic acid, all of which have acid properties.\* The substances which convert gelatine into a body insoluble in hot water appear to have the common property of supplying oxygen, either directly or in presence of water. In the class of mineral bodies giving gelatinous precipitates insoluble in hot water are chlorine, bromine, ferric, uranic, and manganic salts, permanganates, gold chloride, and platinum chloride. Among the organic substances we have found only gallo-tannic acid (tannin) which is capable of giving (in the case of the gelatine solutions) a precipitate which can be re-dissolved in hot water.

\* The salts of phenol and of naphthol-sulphonic acids do not precipitate solutions of gelatine.

The compounds rendering gelatine insoluble in warm water but without precipitation are as follows:—

*Mineral.*—Chromium salts.

*Organic.*—Formaldehyde, quinone, quinhydrone, quinaldine, and the oxidation products, more or less defined, the following phenols: pyrocatechin, hydroquinone, resorcin, pyrogalllic acid, and monochlor-hydroquinone.

In the case of mineral salts it is noticed that the insolubility of the gelatine does not appear to be merely a result of oxidation, but the gelatine fixes a certain quantity of the salt, causing insolubilisation. This oxide of itself to the gelatine only when it can be formed in the solid state. In the case of organic substances the oxidation of the gelatine appears to be accompanied by the fixation of an organic residue. In the case of the action of formaldehyde, for example, it is known that the formaldehyde can be removed from gelatine which it has rendered insoluble by boiling with water, but no other experiment can be put forward as definite proof that a similar process goes on in the case of the quinones and their derivatives. For these bodies cannot be recovered, and the percentage composition of the gelatine does not allow of any conclusion being drawn.

## THE HOLLINGER LIGHTING.

[A feature of the present American professional conventions—introduced, we believe, by Mr. Pirie Macdonald—is a series of demonstrations of their methods of working by leaders in the professions. Thus at a New York convention now being held Mr. Hollinger of that city is showing the system which he uses in obtaining portraits which are characteristic of his work. Apropos of this we may quote a short description of the Hollinger method from the encyclopædia of practical photography to be shortly issued by the American School of Art and Photography, 215, Washington Avenue, Scranton, U.S.A.—Eds., "B.J."]

ALTHOUGH the "Hollinger" lighting belongs to the low key style, it is not "freaky." It gives extremely pleasing results, and truth-

manner. While this lighting may be produced in any key, a medium tone is to be recommended.

For this style of work it is necessary to use an open, or open skylight. Referring to Illustration No. 1, you will observe the arrangement and the position in which the subject and accessories are placed. The operating-room should have a height from 4 to 6 ft. of space beyond either end of the light. In every case, the room is short and the skylight is built very near to the back of the room, thereby not allowing sufficient space for the subject, the proper space can be supplied by drawing one opaque shade down the entire length of the light, if your subject is a single slant. If a hip light, draw one of the top shades down to the top of the side-light, and then the side shade from the bottom of the top of the side-light. This will be of material aid, as it reduces the size of the light the width of this shade. Placing the background directly under the light would strongly illuminate the subject and cause the background effect to appear coarse, harsh, and instead of soft and diffused as it should be.

### Lighting the Subject.

Refer to Illustration No. 2 and observe that the skylight is almost wide open, there being sufficient space beyond the subject to the skylight to arrange the subject and background. The first shade used is the first one on the skylight, which has been drawn, preventing strong light from being carried too far to the face. For this variety of lighting the subject must be placed back from the light to permit all the illumination to fall on the sitter from the front.

### Controlling the Light with the Diffusing Screen.

The light is controlled entirely by the diffusing screen, which is placed between the light and subject, while the tone, or key, of the light, is obtained by placing the screen closer to, or farther from the sitter. If the diffusing screen were not placed between the light and the sitter, heavy shadows and strong high-lights would result. In fact, the effect would be quite contrary. By drawing the extreme high-lights with the diffusing screen, the same effect is also performed for the shadows. Experiment by placing

fully reproduces the likeness of the individual. For portraits of men there is no stronger or more effective form of lighting, as the character of the subject is brought out in the best possible

the screen at various distances from the subject, observing the different effects produced.

When using the diffusing screen think of it as your skylight. By opening, or closing, the small curtains at different places on the screen, and also by tipping the screen forward at the top, every ray of light can be controlled and directed to secure the desired result. For this style of lighting all the dark opaque curtains could be drawn on the diffusing screen, except, perhaps, the top one. Where the opaque curtains cut off too much light from the drapery, separate them to allow the illumination to filter through the tan curtains on to the drapery, thus supplying catch-lights. The narrower the opening the more concentrated and snappy will be the catch-lights, while the increased separation of the black curtains produces broader light upon the drapery. By properly

pulling the screen, sketchy effects may be obtained, with soft negatives full of detail and atmosphere. It is essential that there should be detail in the drapery, as well as in the shadows of the face. Photographers sometimes carry this diffusion to the extreme, losing all semblance of detail in the drapery. This is wrong. There should be sufficient detail in the drapery to leave no doubt as to the texture of the material. It is far better to light the drapery a tone higher than too low.

To make a successful "Hollinger" lighting, the eye should be trained to observe the most delicate high-lights. This is essential in judging when the proper effect has been produced. The high-lights need not be prominent on the face, but the most delicate must be preserved in the development. For your first work it is better to use a rather high key of light, and, when once familiar with the different methods of lighting, you may then experiment and work for a lighting in a lower key, but avoid going to the extremes.

For "Hollinger" lighting the person being posed should be placed back from the light, permitting all the illumination to fall on the face of the subject. By reference to the diagram of the floor you will observe the exact position of the different accessories making the illustrations. As conditions are not the same in all studios, it may be necessary to alter the positions somewhat to suit the room in which the work is being done; but the diagram will serve to illustrate clearly the manner in which the lighting is effected. The principal points to remember are, that practically no light must be employed; that the subject is placed back from the direct light, and also away from the side light; and that the key of light is controlled by the diffusing screen between the subject and the sitter. As this lighting is delightfully soft, it is particularly well adapted to almost any style of pose, sitting positions, standing positions, or half figures being most attractive under this lighting. For group positions of men, or women, give beautiful results. It is particularly effective for children's portraits, because they are made to advantage in a higher key.

## EXAMINATIONS IN PHOTOGRAPHY.

To talk of examinations when the English weather is giving signs of repeating its splendid June programme during August, may appear a peculiarly inopportune thing to do, yet the fact remains that within little more than a month the summer will be waning and the season of lectures and classes upon us. And therefore, on the principle that it is always better to be too soon than too late, attention may be drawn to the examinations held annually in the spring by the City and Guilds of London Institute in photography as well as in some score or more of other branches of technology. We are not champions of the examination system. We acknowledge that it induces a habit of mind which in many cases turns out to be by no means the best for the future welfare of the student. But, on the other hand, one must not lose sight of the great merit of an examination—namely, that it inspires and sustains interest in a course of study which, in the absence of such a stimulus, would most likely not be entered upon at all. For that reason, and also because the study of the principles of photography are so largely disregarded both by amateurs and those who are to engage in photography as a business, we would draw to the notice of our readers the papers of questions and the practical examinations held in London and provincial centres by the "City and Guilds." This examination is divided into two divisions:—

### A.—Pure Photography.

#### B.—Photo-mechanical Processes.

Each of which is again sub-divided into the Ordinary and Honours grade. In each grade a paper of questions is set, and in the "Honours" in both Sections A and B the student must enter a practical examination.

Full particulars of the places where the examination is held can be obtained from any technical school in London—the Polytechnic, Regent Street, particularly interests itself in the examination—and the City and Guilds Institute, in the prospectus issued from its Examinations Department, Exhibition Road, gives all other particulars, and recommends the text-books most helpful to intending examinees. The following are the papers and practical tests set at the last examination:—

### A.—PURE PHOTOGRAPHY.

#### ORDINARY GRADE.

Eight questions only to be attempted.

1. Do you approve of the plan of keeping the developer in motion while developing a dry plate? If so, why, and to what extent? What ill effect, if any, would you expect to follow if the solution were allowed to remain still? (30 marks.)
2. In developing a plate known to have had four times the correct exposure, how would you proceed so as to obtain the best result? (40.)
3. Give formulæ for toning solutions for (1) albumenised paper, (2) P.O.P., (3) collodio-chloride paper. (40.)
4. What kind of plate would you use for copying to the same size as the original (1) a manuscript with faded writing, (2) a water-colour painting in colour; and what plate for making an enlargement to two diameters from a print on albumenised paper? How would you illuminate the originals in each case? (50.)
5. Platinotype paper is sent out in hermetically sealed tins with a quantity of drying agent enclosed. Why is this method of packing adopted, and what would be the result if it were packed in the manner usual with P.O.P., bromide paper, etc.? (30.)
6. How would you store a supply of platinotype paper, judged to be sufficient for one day's use, for a number of negatives of different sizes? Taking 5½ in. by 4¼ in. as the size for printing "cabinets," how would you cut up to the best advantage a sheet 26 in. by 20 in.? Ditto for whole-plate negatives? (40.)
7. Describe how you would proceed to make a so-called vignette head and bust from (1) a quarter-plate with a half-length figure, and (2) a 12-in. by 10-in. negative of head and bust, the head being 3 in. long. (40.)
8. What do you understand by the term "anastigmatic lens" for photographic purposes, and how would you proceed to ascertain the focus of one of them? Give an example of a suitable method. (50.)
9. In using a whole-plate camera, fitted with lenses of wide-angle capabilities and of 8-in. and of 14-in. foci, the negatives obtained were sometimes foggy and at other times free from fog.

Can you suggest an explanation, and a remedy not connected with plates or dark-room? (45.)

10. If you had to make a large number of smaller prints from a whole-plate negative that had a small crack extending from the side, through an entirely useless margin, to within a quarter-of-an-inch of the portion to be printed from, what danger would you apprehend from the crack, and how would you provide against it? (50.)

11. In "spotting" prints, i.e., removing casual blemishes, how would you proceed, and with what materials, to remedy (1) a light spot with darker surroundings, (2) a dark spot with lighter surroundings—with platinotype paper and with P.O.P.? (40.)

12. What fittings would you wish for so as to be able to use half-a-dozen lenses of different sizes with one camera? (25.)

13. Describe how you would retouch a portrait negative. What special treatment would you give one in which the face shadows were much too heavy? (40.)

#### HONOURS GRADE.

Seven questions only to be attempted

1. Describe two methods of intensifying a negative. (25 marks.)  
2. What effect does the addition of potassium bromide to the developer have (1) before the development is commenced, (2) after the image has commenced to appear? (25.)

3. A new colour-sensitive plate is put into your hands, and it is to be used in copying paintings to give the proper value of the colours in monochrome. Describe the method you would adopt to obtain a proper screen. (40.)

4. Having a "single" photographic plano-convex lens of 6 in. focus, the convex surface being outward, and a *bi-concave* lens of 2.88 in. focus, it is required to make a combination which will come to a focus for a distant object on a screen 18 in. away from the convex surface of the photographic lens. What will be the distance apart of the plano-convex and the concave lenses, and what will be the focal length of the combination? The concave lens is to be between the photographic lens and the screen. (50.)

5. Describe how you would make an enamel of a head and bust on an oval plaque 3 in. in longest diameter and 2 in. in shortest diameter, the head to occupy one-third the length of the oval. On the original negative the head was 2 in. in length. (35.)

6. What effect has (1) ozone, (2) sulphuric acid, (3) bichromate of potash, (4) hydrochloric acid, (5) permanganate of potash, on the undeveloped photographic image impressed on a collodio-bromide plate? (30.)

7. In some cases manufacturers recommend that their plates (colour-sensitive) should be manipulated in darkness. Is this an absolute necessity? If not, what light should you use? Give reasons for your answer. (25.)

8. Describe some process in which iron salts are the sensitive salts. (30.)

9. In what way does a backing to a plate mitigate halation? Give the essentials of a good backing. (30.)

10. Describe the development of an Autochrome plate and its conversion from a negative into a positive. How is the effect of colour produced, and are the colours theoretically correct? (40.)

11. A lens is made of glass having a refractive index of 1.5. It is plano-convex, and has a focus of 9 in. Neglecting the thickness of the glass, what will be the radius of curvature of the convex surface? (25.)

12. Describe what is meant by the efficiency of a shutter. (35.)

#### PRACTICAL EXAMINATION.

Candidates may select any two of the following tests.

1. Copy the engraving given you, making the copy as large as possible on a half-plate. The density on the parts of the negative representing white should be such as to allow a print to be made showing good blacks and good whites.

2. Make an enlargement on bromide paper of a whole-plate size from the quarter-plate negative furnished to you.

3. Print, develop, and fix a platinotype taken from the accompanying negative.

#### PHOTO-MECHANICAL PROCESSES.

##### ORDINARY GRADE.

Seven questions only to be attempted.

1. Describe any form of camera suitable for copying purposes. What are the essential conditions which the apparatus must fulfil?

Why are copying cameras sometimes "swung," and what methods are adopted for swinging? What are the drawbacks to such systems, and what alternative method would you suggest should be adopted? (50 marks.)

2. Give a simple description of an "open" and an "enclosed" electric arc lamp suitable for use in a process studio. Has the "enclosed" arc lamp any advantage over the "open" arc lamp, and if so, for what reasons? (30.)

3. Write a brief account of the wet collodion and gelatino-bromide dry-plate processes. Why is the wet collodion process generally preferred by those who prepare negatives for the photo-mechanical processes? (25.)

4. What do you understand by the terms "alkaline" and "acid" development respectively? Comparing the negatives produced upon a wet collodion plate and upon a gelatino-bromide dry plate, what respects do the images differ? (50.)

5. Describe the appearance of the following named substances: Dragon's blood, stearin, glycerin, oil of spike, pyroxyline, guaiacum, asphalt, pitch, bitumen, fish glue, colophony, albumen, celloidin, beeswax. How are these bodies obtained and what are their principal uses? (50.)

6. Describe the enameling process. By what means can you vary the character of the print obtained from a given negative? How can you produce differences in the sensitiveness to light of the film? (50.)

7. How would you prepare a solution of ferric chloride suitable for etching copper plates? What means would you adopt for ascertaining the concentration of the solution? Why are solutions of different concentrations used in the process of etching? (25.)

8. What is a "glazed" roller, and how may such a roller be made? In what process is it used, and why is this particular kind of roller necessary? (25.)

9. Give a description of the Mark Smith etching machine, and state how it is used. Your answer should be illustrated by a simple sketch in outline, showing the essential parts of the machine. (30.)

10. What is the Vandyke process? Explain the principle, and give an outline of the working of the process. (30.)

11. Describe carefully the regular cross-line screen, the irregular grain screen, and the metzograph screen, and explain how they are used in photo-mechanical photography. (40.)

12. What is an "orthochromatic" process dry plate? In what respects does it differ from an ordinary dry plate? (25.)

#### HONOURS GRADE.

1. Explain the different ways in which *continuous* or *closed* tones are translated into *broken* or *open* tones for the purposes of photo-mechanical photography. So far as concerns visual effect, what is the underlying principle in these methods? (50 marks.)

2. Describe a practically useful process by which collodion plates prepared by the bath method, may be rendered sensitive to the refrangible regions of the spectrum of white light. (30.)

3. You are required to produce from a painting in oil colours a "half-tone" type-high block, a print from which shall be a correct transcript in monochrome. Describe in detail the method you would adopt, and state your reasons for such procedure. (50.)

4. Write an account of the method of producing a print by the collotype process. How do you explain the formation of "grain" (reticulation) in the film of the collotype plate? (35.)

5. What is a mercury vapour lamp? Describe the different parts of an installation of such lamps, and state for what purposes the installation can be usefully employed in a "process" studio. (30.)

6. You are required to produce the process blocks to illustrate a catalogue of silver ware. Amongst the objects are a number of small brushes with metal backs in bas-relief. How would you proceed in order to make the best illustrations of these objects? (30.)

7. Describe any process with which you may be acquainted for the production of mechanical "overlays" for use in the printing of half-tone process blocks. (20.)

8. Give an outline of the method of making an intaglio plate from an original drawing in line. Is a grain necessary, and if so, what is it necessary? (35.)

9. What is the Schultze screen, and what are the advantages claimed for it? (20.)

10. Describe a process for making pyroxyline. What solvents are used in making collodion and in what proportions are they?

employed, and what proportion of pyroxyline to solvents is usually used? How would you prepare a collodion suitable for line work in the wet-plate process? (35.)

Name the chief sensitisers employed in orthochromatising dry plates, and state the particular spectral regions for which they produce an increase in the sensitiveness on silver bromide. How would you in practice use these substances? Point out any difficulties and defects which are likely to occur. (50.)

Three bodies—mercuric oxide, lead chromate and zinc oxide—placed side by side and are examined in sunlight. When asked to describe their appearances, you say that one has a "red" colour, another a "yellow" colour, and that the remaining one is "white." Explain fully what you mean by these terms. Is this quality you call "colour," and the particular colour observed, in any way dependent upon the conditions under which you are examining the plates, and if so, what is the cause of the phenomenon? (50.)

Certain processes for the pictorial rendering of coloured objects by photography are said to be "synthetic" and others "subtractive." What is the difference? How are yellow and bright red produced in the synthetic and subtractive processes respectively? (30.)

#### PRACTICAL EXAMINATION.

Candidates may select either of the tests from any one branch, I., II., or III., but they may not take tests from more than one branch.

#### Three-Colour Process.

(a) A set of three-colour filters and sensitive plates, to which they are adjusted, are provided. You are to make, from the coloured original given, a set of direct screen negatives, and to produce prints upon copper from the negatives by the enamelling method. (60 marks.)

(b) Make a set of three-colour continuous tone negatives from the object supplied, and from the negatives make a set of contact transparencies suitable for screen negative making. (40.)

#### Half-tone Block Making.

(a) Make a screen negative from the half-tone print supplied, of the same size as the original. Print on zinc by the enamelling method. Etch the plate and make a clean proof. (60.)

(b) From the negative supplied, print and etch a plate, make a proof and afterwards fine etch the plate, and finally make a careful proof to show the state of your work. Submit both proofs together with the plate. (40.)

#### Fine Line Block Making.

(a) Make a negative from the fine line original supplied. Print on zinc, transfer tint to parts indicated and make ready for etching. (60.)

(b) Make negatives from the originals supplied, to different scales upon the same plate. Make a print on zinc and etch the plate. (40.)

#### FORTHCOMING EXHIBITIONS.

September 11 to October 24.—Photographic Salon. Entries close August 31. Sec., Reginald Craigie, 5A, Pall Mall East, London, W.

September 17 to October 24.—Royal Photographic Society. Entries close September 1. Sec., J. McIntosh, 66, Russell Square, London, W.C.

October, 1908, to January, 1909.—Kiew International Photographic. Sec., S. T. Horovitz, Technical Society, Kreshtchatik, Kiew, Russia.

1909.

October 6 to 27.—Northern Photographic (Manchester). Entries close December 11, 1908. Sec., S. L. Coulthurst, Broad Oak Road, Worsley, Manchester.

PHOTOGRAPHY AT MIDNIGHT.—Mr. R. W. Porthouse, of Carlisle, has made a print from a film negative taken on July 1, from 11 p.m. to 12.15 a.m. The subject, a landscape with a lake foreground, received an exposure of seventeen minutes, the film being of speed 78, and the stop,  $f/8$ . Except for the slight blur of two boats in the foreground, due to their movement, the photograph has the appearance of a full exposure made towards

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between July 20 and 25:—

CAMERA.—No. 15,403. Improvements in photographic camera. Herbert George Chessher, 68, High Holborn, London.

SHUTTERS.—No. 15,548. Improvements in and connected with photographic shutters. Frank Whitehead and Walter Frederick Giles, trading as F. Whitehead and Co., 34, Pickets Street, Balham, London.

CAMERAS.—No. 15,608. Improvements in photographic cameras. The Thornton-Pickard Manufacturing Co., Ltd., Arthur Gray Pickard, and Arnold Shepherd, 6, Bank Street, Manchester.

DEVELOPERS.—No. 15,657. Improvements in or relating to photographic developing and fixing solutions. Felix Jeannot and Maxsted R. Bremner, 111, Hatton Garden, London.

TELEPHOTOGRAPHY.—No. 15,817. Improvements in telephotographic apparatus. Pascal Berjonneau, 20, High Holborn, London.

PLATES.—No. 15,866. Improvements in or connected with photographic films or plates. James Hugh Collingwood Sproule, 40, Chancery Lane, London.

#### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

COLOUR PHOTOGRAPHY.—No. 10,611, 1907. Patent has been granted to the following process, the essential part of which will be recognised as identical with that associated some eight or nine years ago with the name of Mr. Friese-Greene, and referred to in another page under "Ex Cathedra." The camera is provided with a rotating disc arranged to rotate at any desired speed, which disc consists of three light screens or filters, violet, green, and orange respectively, with opaque intermissions, arranged to pass the lens of the camera alternately during the period of exposure at the proper speed and regularity. The only condition which is necessary to observe with this combination or arrangement of apparatus is that the disc shall exclude from the sensitive plate all light except such as passes through the screens, and the screens should be of such size or the disc so arranged that the whole of the desired light picture is produced and thrown upon the plate. With the disc properly constructed, no intermissions are required, and if operated in a good light the time of exposure should be approximately the same as without the disc.

The three pictures corresponding to the three colour-sensations are thus blended into one natural-colour light picture by the action of the disc.

In applying the method to produce pictures in the natural colours, a bichromate plate is exposed under a dry plate diapositive in the usual way. The best plate for this purpose is the one which would best respond proportionately to the various intensities of white light. The plate may combine special sensitisers or sensitisers combined with pigments to obtain special results, selected with due regard to the character of the light picture to which the plate is exposed.

The positive bichromate plate, when properly printed and prepared, is then immersed in a suitable blue dye bath and dyed. When the darkest part of the picture appears on the plate in a deep blue colour, or when a blue picture full of detail appears, the plate is then sufficiently dyed and the proper proportions of blue are found distributed throughout the picture, thus making a blue print of the original object. The plate is then washed in running water until the surface dye is removed. This washing is repeated after each dyeing. The plate is then immersed in a red dye bath for the proper length of time, as determined by subjecting a similar plate to a red dye bath alone, or by observation during the process conducted in accordance with the laws of the mixing of colours. Thus the effect is produced of blending a blue print and a red print of a given object on the plate. The plate is then immersed in a yellow dye bath, and similarly a yellow print of the

given object is blended with the others. The result is a natural colour picture of the original object on the plate, from which copies can readily be taken by any of the methods known to practice. Burton Stearns Philbrook, 166, Remsen Street, Brooklyn, New York, U.S.A.

**CINEMATOGRAPH SHUTTERS.**—No. 24,525, 1907. The invention consists of an improved form of automatic shutter for cinematograph projectors and controlling gear, by means of which the light from the projecting lantern is automatically screened from the film when the film is not moving. The invention is an improvement on that described in Specification No. 10,047, 1898, and has for its object a simplified means of fitting the shutter to the gate of the projector, which has to be movable, while the operating mechanism is carried on a fixed part of the machine.

The shutter consists of two metal plates running in a pair of horizontal slides, which are attached to the gate of the projector, the two plates being connected together by a lever or levers so that they always move together, but in opposite directions. The operating mechanism consists of a centrifugal governor built in the flywheel which is usually mounted on one of the fast running spindles of the machine. To transmit the movement from the governor to the shutter on the gate we use a wire inside a flexible tube either in the form of a flexible shaft or the well known Bowden wire. Ernest Francis Moy and Percy Henry Bastie, Greenland Place, Camden Town, London, N.W.

The following complete specifications, etc., are open to public inspection before acceptance under the Patents Act, 1901:—

**SCREENS.**—No. 7,739. Method of manufacturing line and point screens. Veremigte Kunstseide-Fabriken Akt.-Ges.

**COLOUR PHOTOGRAPHY.**—No. 15,950. Photographic reproduction of colours. Caille.

### New Trade Names.

**LINSOL.**—No. 303,264. Chemical substances used in manufactures, photography, or philosophical research and anti-corrosives. Williams Brothers and Co., The Clarence Chemical Works, Hanworth Road, Hounslow, Middlesex, aniline dye manufacturers. May 21, 1908.

**STERISALT.**—No. 303,581. Chemical substances used in manufactures, photography, or philosophical research and anti-corrosives. Thomas Kerfoot, trading as Thomas Kerfoot and Co., Bardsley Vale Mills, Oldham Road, Bardsley, near Ashton-under-Lyne, Lancashire, manufacturing chemist. June 2, 1908.

**SUNBEAM.**—No. 301,048. Photographic cameras, slides, plateholders, and shutters included in Class 8. Thornton-Pickard Manufacturing Co., Ltd., Atlantic Road, Broadheath, Atrincham, Cheshire, manufacturers of photographic apparatus. March 6, 1908.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### The Photography of Doorways.

It is seldom advisable (writes Mr. E. W. Jackson in "Photography and Focus" for August 4) to photograph a doorway from a position directly in front. The camera should be placed a little to one side. This tends to give more variety of line from the altered perspective. A stand camera is undoubtedly preferable for this class of work. As the camera has frequently to be pointed upwards in taking large doorways and porches, the swing-back will often be brought into requisition. A level, too, will be found useful.

As a further aid to pictorial effect, an effort should be made to show an attractive foreground in doorway pictures. Nothing looks worse than to see a doorway or porch cut off close to the base of the structure. A few steps, some foliage, or a play of light and shade may make all the difference in the world between an uninteresting and a picturesque representation.

In development, also, care must be taken to avoid harsh contrasts—i.e., brilliant light and deep shade. To this end the normal

strength of the developer may be diluted, or the total time development kept short. A further most useful "dodge," printing by gaslight more especially, is to use a tuft of cotton-wool at the end of a fine wire. This kept in motion (with a circular action) in front of the darkest parts of the doorway will keep the exposure to any required extent.

### Lighting in Portraiture.

There is often an inclination (writes Mr. C. H. Hewitt, in "Amateur Photographer and Photographic News" for August 4) to soften the lighting of the face, as though well-marked cast shadows were objectionable *per se*. The result of such a course is general insipidity, and the portrait degenerates to the commonplace. Shadows are objectionable only when they are harsh, but if the plate has been properly exposed and over-development has been carefully avoided, the shadows strengthen the character of the portrait by emphasising the modelling of the features. Not vigorous lighting is the royal road to characterisation, but still that it is a road well worth following if the technical difficulties are properly mastered. Nor need the idea that strong lighting is unsuitable to the old and rugged face be clung to.

Quite frequently a portrait may be made interesting by the lighting alone, and a charm given to one's work which is altogether independent of the beauty or character of the model. There is always a fascination in some unforeseen play of light, but nature is enhanced if a beauty of contour or modelling is brought out. It is well also to remember that the flatter lightings do not do anything like the opportunity for hiding defects which exist. The light and shade are rather more forcibly expressed. In fact, it may be taken for granted that the success of a portrait, not only as a satisfactory likeness, but also as a piece of pictorial photography, depends quite as much on the reserve with which proportions are treated as on the emphasis given to the beauties of contour or modelling.

## New Apparatus, &c.

The "Minimum" Pocket Ruby Lamp. Sold by W. Butcher & Sons, Ltd., Camera House, Farringdon Avenue, London, E.C.

A portable ruby lamp, which is sufficient for changing plate when developing a plate or two en route, is a most useful addition to the tourist's outfit, and it cannot be said that much is offered in the purchase of such an accessory. Messrs. Butcher & Sons, in the new apparatus before us, have certainly reduced the size of the lamp to the minimum proportions, and have given their

reduction a form which should appeal to the tourist. For the apparatus is entirely self-contained, and though the size of the glass is not great (2 x 2½ in.), the illumination is sufficient for the night-time changing of one's plates. The lamp consists of a small box, 2½ x 3½ in., which throughout is rivetted together, and is

with trapped inlet and outlet for ventilation. The illuminant lamp burning benzoline, the tiny reservoir being supplied with benzoline which is only to be saturated with the benzoline when the lamp. The reservoir, as shown in the second illustration, within the lamp when travelling, and the whole apparatus can be carried away among other luggage without fear that it will leak or contaminate grease to any clothing with which it comes in contact. The price of the "Minimum" pocket lamp is 2s. 6d.

**Maitland" Composing Gauge.** Sold by W. Butcher and Sons, Ltd., Camera House, Farringdon Avenue, London, E.C. A most useful aid to the trimming to odd sizes of any prints up to 7 in. is provided by this invention of Viscount Maitland, an example of which appeared among the "Patent News" in the "British Photographer" last year, the actual means for utilising the device being placed on the market by Messrs. Butcher. The composing gauge consists of a thin sheet of almost transparent tracing paper accurately into  $\frac{1}{4}$ -in. squares. In using it, the gauge is laid over the print, and the portion which it is desired to trim down to the

rectangular shape is then marked on the print by passing a needle through the point in the gauge. It is then only necessary to draw a straight-edge from point to point, preferably on the print where the points are more clearly visible, and the portion of picture is then obtained perfectly square and without trouble of measuring or gauging the truth of the right-angled corners. Twelve of these ruled gauges, fixed to a cardboard back, and packed in a box which is sent out, complete with instructions for use, at the price of one shilling.

## Meetings of Societies.

**FRANKWATER BUTT, F.R.P.S.,** has, owing to termination of his contract, moved from his late address at Hammersmith to Roseneath, 13 Athor Road, Shepherd's Bush, W., where he may be consulted on all matters relating to photography, and particularly on the construction and fitting-up of studios, on which subject the series of articles in our pages have afforded one illustration of his knowledge.

## Commercial & Legal Intelligence.

**PICTURE POSTCARD DISPUTE.**—In the Lord Mayor's Court, last week, Messrs. F. E. Fry and Co., photographic printers, sued Mr. Garner, picture postcard publisher, of Leicester, for the price of picture postcards. Mr. Givern (instructed by Mr. Joseph) was counsel for the plaintiffs, and Mr. Trapp (instructed by Mr. Phillips) for the defendant. The plaintiffs' case was that an order was given on the terms of sale or return. Credit was given for returned cards, and the balance sued for was due. The Assistant Judge said that but for the question of costs he and the gentlemen of the jury might subscribe the amount, 11s. 8d. He thought that such a dispute might have been settled by the toss of a coin. The defendant's case was that all the cards received back from their customers had been returned. There was delay in delivery, and a counterclaim was raised for 17s. 6d. for preparing a negative which was of no use in consequence of the late delivery. The jury found a verdict for the plaintiffs on the claim and counterclaim.

**CANVASSING CASES.**—At the Greenwich Police-court, on Thursday last, Jacob Garcia, aged 24, of Emmanuel Street, Mile End, was charged with embezzling 2s. belonging to his employer, Alfred Mitchell, photographer, of 97, Woolwich Road, East Greenwich. Prosecutor stated that prisoner was employed as canvasser and collector at a weekly wage of 17s. 6d. He had a shilling from customers for which he did not account. He went out on June 27 to collect, but did not return, and a warrant was issued. Two witnesses having given evidence that they had each paid prisoner 1s., Detective-sergeant Wilson stated that when he arrested the accused he admitted having the money, and said that if he had been given the opportunity he would have paid it back. He had tramped to Liverpool and Manchester looking for work, and returned "broken-hearted." Accused now said that he had lost a sovereign out of his pocket, and did not like to face prosecutor. He admitted that he had already been convicted for a similar offence. He was sentenced to one month's hard labour.

Sentence of sixty days' imprisonment was passed by Acting Sheriff Pitman, in Edinburgh Sheriff Summary Court last week, upon a man named George Wood, described as a photographer, who pleaded guilty to having fraudulently obtained 8s. 6d. from ladies in Leith, by pretending to take their photographs.

## News and Notes.

**PICTURE FRAUDS IN GERMANY.**—A remarkable trial will shortly begin in Munich (writes the Berlin correspondent of the "Chronicle") of about twenty persons accused of falsifying pictures, supplying them with signatures of well-known masters, and selling them as original works. It is not believed that the painters of these pictures—most of which copies have been admirably executed—are accessory to the fraud, or that the best art dealers in Munich are privy to the doings of this gang, but there are certain strange matters which want clearing up, and which the trial will do much to elucidate. It is computed that during the last eighteen months something like 700 pictures, most of them copies of French works, have been sold in Munich as originals to wealthy buyers whose knowledge of art subjects is limited.

**THE HEALTH RESORTS DEVELOPMENT ASSOCIATION**, 29, John Street, Bedford Row, W.C., have added four new booklets, dealing respectively with the districts of East Grinstead, Skegness, Llandrindod Wells, and Weybridge, to their well-known and popular series of official guides. These booklets contain much useful information and are well illustrated, and may be obtained free by sending a postcard to the respective town clerks.

"COUNTRY LIFE" announces a competition for the three best photographs of children playing, paddling, castle-building, or engaged in any other seaside game or pastime. Prizes of £5, £2,

and £1 will be awarded, under conditions as follows: The photographs should be silver prints, preferably on printing-out paper, not smaller than half-plate size, and should be carefully packed and addressed to the Editor in a parcel bearing the words "Photographic Competition" on the outside. For the purpose of identification each individual photograph must be clearly marked with the name and address of the competitor. It is understood that all reproduction rights of the successful photographs will pass to the Proprietors of "Country Life," and, if required, the negatives of these pictures will be given up to them. The Proprietors also reserve to themselves the right to make use of any of the unsuccessful photographs upon payment of 10s. 6d. for each picture published. The competition will close on September 10, and the decision of the Editor—which will be final and without appeal—will be announced as early as possible after that date.

**A CAMERA CLUB FOR ST. ALBANS.**—At a meeting of St. Albans photographers, held last week, at which the Mayor presided, a formal proposition that a camera club should be formed was submitted by Mr. Coleman, who remarked that many of those present were members of the old photographic society, which was now practically non-existent; they had done nothing for the twelve months as a club. He thought he could speak on behalf of the committee of the old club when he said they would be pleased to help the new club, who perhaps might be able to take over what remained of the old club in the way of apparatus. The Mayor emphasised the point that the society was not being formed in any spirit of antagonism towards the old organisation, and the Rev. J. Aldred said he had been assured by several members of the old society that they were not only willing that a new society should be started, but would gladly co-operate in its formation. After a somewhat lengthy discussion the resolution for the formation of the club was carried, all present signifying their desire to become members, and the following officers were appointed: President—the Mayor. Committee—Messrs. C. H. Ashdown, Coleman, R. H. Shields, F. T. Usher, and T. Butler. Joint hon secretaries—Rev. J. Aldred, Berrystead, St. Peter's Road, St. Albans; and Dr. Puddicombe, London Road, St. Albans. The subscription was fixed at 5s. per annum, but members joining at once would not be required to renew their subscriptions till Christmas, 1909.

## Correspondence.

- \*• *We do not undertake responsibility for the opinions expressed by our correspondents.*

### A FRAUD ON PHOTOGRAPHERS.

To the Editors.

Gentlemen,—I should like to be able, through the medium of the "Journal," to warn other photographers of a man who poses as a retired farmer and called on me the other day and gave an order for photographing a house from several views. He was particular that 12 by 10 negatives should be taken, and arranged for four views and one dozen copies to be supplied of each. The date and time for photographing was fixed, and the farmer was to send his own conveyance to fetch my apparatus, etc., as he stated that the house was more than a mile from where the 'buses stopped.

Two days later he called and postponed the appointment to a later date, and as he was leaving the door inquired the fare to a certain place in the West End, and on being told that the fare was threepence he casually remarked that he had left home with one penny only in his pocket, and as he was a prospective customer for several pounds I offered to lend him sixpence. He at first demurred, saying he would take a penny fare and get a cheque cashed. I pressed him to take a small coin, and he thought for a moment, and then answered, as he would be under an obligation to me for sixpence, would I lend him a shilling? I thought it rather strange,

but gave it him, and have never seen or heard any more of him. The conveyance did not arrive at the time appointed. On my inquiries I found the name and address a false one. The man was rather shabbily dressed, and has the appearance of being eccentric. He no doubt gets a very good living duping photographers in this way.—I am, faithfully yours,  
Kensington, W.

### DIAGRAM LANTERN SLIDES.

To the Editors.

Gentlemen,—To the useful article "On the Making of Diagram Slides" in to-day's issue of the "B.J." I may add the "warning" that to obtain a dead black line with the pure Indian ink—the writer is quite right in stating it is best to use freshly mixed ink, up with water in a proper china palette (which, by the way, should have a cover to keep the ink moist and free from dust during use)—it is only necessary to add a small quantity of water-colour when the gloss will give place to a dull black that will require without any necessity for washing the drawing.—I am, faithfully,  
DRINKWATER BUTT, F.R.S.

Roseneath Studio, Cathnor Road, Shepherd's Bush, W., July 31, 1908.

To the Editors.

Gentlemen,—In an article on this subject appearing in your issue of July 31 Higgins's ink is recommended as the next best substitute for pure Indian ink in the preparation of the line diagrams for slide reproduction.

I feel constrained, as the result of some comparative experiments I recently made on various black inks, to put in a plea for a product in this connection. The experiments seemed to me to conclusively the superiority of Winsor and Newton's "Black" over Higgins's ink. This superiority is due not so much to any great difference in actinism between the two blacks as to complete absence in the case of Process Black of a certain graininess or speckling in the whites of the negative, which is very ably get when copying a diagram made with Higgins's ink. The speckling is very marked in the thicker lines, and in colour washes laid on by brush. Furthermore, it is by no means removed by Howard Farmer's reducer.

As your articles were evidently intended for novices, it well to refer to a point of great importance in lantern slide which receives no mention in the articles—the temperature of the hydroquinone developer. The importance of this factor is to obtrude itself in the dog days, but in winter it brooks of no if one would obtain negatives that can be printed from direct out intensification. The temperature of the developer for good blacks should certainly be not lower than 20 deg. C. (68 F.) at the lowest.

It is further stated in the article that spotting out is required. This is unhappily too true, if the commercially prepared plate is used. The necessity for this troublesome operation, however, avoided if the backing is applied just before taking the negative. This is not the messy and *zeit-raubend* process that so many think it. My practice is to brush a little of Johnson's caranum on the plate, avoiding the margins for cleanliness' sake, and process plates this can be safely done in a good working light sheet of paper is then placed over the backing. (I find the same papers used by the Leto Company for their Seltona paper, the quality for the purpose. It adheres well, and does not back to penetrate.) The plate can then be put at once in a dark slide without any preliminary drying, and without the risk of soiling the dark slide.

I consider "home" backing not merely advisable, but absolutely essential, in printing transparencies in which there are pale continuous tone. It is easy enough, though tedious, to stop the pinholes in the opaque of a line negative; it is an achievement which carries distinction with it to be able to unrecognisably spots in, say, the cloud or the continuous background of a transparency.—Yours truly,  
Blackheath, London.

DOUGLAS CARR

# Answers to Correspondents.

matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

respondents are informed that we cannot undertake to answer communications through the post. Questions are not answered as the names and addresses of the writers are given.

communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., Wellington Street, Strand, London, W.C.

the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street Strand, W.C., undertake the registration of copyright photographs at a charge of 1d. each photograph, to cover cost of registration fee, form, etc. unmounted copies of each photograph must be sent with the

—A result of this kind is obtainable with a duplex carbon e.g., a tissue containing a blue and a sepia film; but we think more likely that a species of double toning (applied to a plate print) has been resorted to. See the article on page 567 issue of July 24.

ER IN CHILD PHOTOGRAPHY.—Would you please give date of "er" mentioned in above article?—AUGUSTUS.

ER FOR CLOUD NEGATIVES.—We should be obliged if you favour us with replies to the following in next week's "B.J." We are informed that it is not generally possible to obtain good effects (even if rapid snaps and cloudy) with pyro soda paper, as with hydroquinone developer. Our contention is pyro is a contrasty developer, and in its action, if developer very much diluted, destroys an otherwise good cloud effect. We had considerable trouble lately, through this cause. Will kindly say if you consider pyro all right for purpose, and if not, hydroquinone a better, cleaner, and more satisfactory developer for commercial work. Also, we should be obliged by you can recommend of hydroquinone for plate-developers.

usually an advantage to use a developer giving fairly good results when making cloud negatives, and our experience is that containing, say, 3 grains per oz.) and hydroquinone are suitable for this purpose. We should usually prefer pyro hydroquinone for commercial landscape, as it is more amenable effects when required, but the choice of developer is largely a matter of personal preference. A hydroquinone formula we have used and would recommend for general work is the second on p. 7 of the "Almanac," 1908.

TERY.—1. I propose erecting a studio. It is to be 26ft. by 12ft. West light, I think, is preferable to east, don't you? 2. You advise ground glass for top and side lights, lean to, or roof?—B. STANLEY.

There is not much to choose between the two aspects, though much may depend upon surrounding buildings. 2. Ground glass will be good, though plain will answer the purpose as well, and can be used with thin muslin, or tracing linen, blinds. 3. As the studio is very much divided as to which is preferable. With a roof the studio can be glazed on both sides, and the light used in the fore part of the day, and the east the later part. If you refer to p. 635 (August 23) of our volume for last year you will find an article that may help you.

OUT.—The print sent is not from a process block. It is from an intaglio plate in a machine. The process of producing the pictures is not published, and the firm that is working on the details as their trade secret. The print has been sent to you as requested.

RY.—I should be obliged if you would give me advice on lighting. I am about to take over a studio, which is 25ft. by 12ft. have a 12 by 12 camera (Forward), and am wanting a lens that I could use for busts, full, and three-quarter

figures and groups, so that with stopping-down would cover 12 by 10. What focus in lens and what kind of lens do you suggest?—NETTA.

The lens best adapted for bust portraits would scarcely be the best for 12 by 10 groups in so short a studio as 25ft. The most generally useful, under the circumstances, will be one of about 15in. focus, working at an aperture of about f/6. If the studio were longer we should advise the next larger size.

REPRODUCTION FEE.—The winner of a 25-mile cycle road race has received a letter from the makers of the cycle he rode congratulating him, etc., and a request that he should have his photograph taken to be reproduced in their 1909 catalogue. I am not charging him for taking his photo, as the cycle firm say he is to instruct his photographer to send the bill in to them. What can I charge—the usual fee for reproduction for advertising purposes, or only my usual price for taking photographs to order?—J. A. G.

If your idea is that when taking the photograph, in the circumstances as stated, you will possess any rights as regards its reproduction, let us say that you are mistaken. You have none, and, therefore, it seems to us that you should charge your usual price for such outdoor work. Really we think you are in a better position to decide than we are.

OSBORNE M/C AND OTHERS.—We will reply to your queries in our next issue.

A. S.—The reply appeared in our issue of July 24. See the rules at the head of this column.

COMBINED BATH.—1. Can you give me a combined bath formula for rich chestnut tones? I have tried borax (enclosed card), and cannot account for yellowness. It was a bath freshly made. 2. Will combined baths keep?—COMBINED.

1. A good bath is:—

Hypo .....	8 oz.
Ammonium sulphocyanide .....	1 oz.
Lead nitrate .....	175 grs.
Alum .....	350 grs.
Water to .....	20 ozs.

Dissolve the hypo in the water, add the sulphocyanide, then add the alum dissolved in a little water and also the lead, and add to the hypo. Heat the mixture to 120deg. F. for ten minutes. Allow to cool. For use take:—

Stock solution as above .....	10 oz.
Water .....	10 oz.
Gold chloride (from stock solution) .....	3½ grs.

The yellowness of your print appears to point to an overworked bath. 2. Certainly, but there is danger in using a bath deficient in gold.

X. Y. Z. (Bombay).—1. Certainly; if you shorten the focal length the camera extension must be likewise shortened. There is no ready way of getting over this. 2. Yes, such long focus lenses are quite unsuitable for the majority of subjects. About 4½in. is the best general focal length. 3. They are very satisfactory for general transparency work, but the grain (not unduly pronounced) is, of course, more in evidence in the stereoscope.

ENAMEL.—Through the stopper of the bottle being left out, or its being blown out, the solvents of the collodion have evaporated. The thick mass in the bottle may be redissolved by the addition of fresh ether and alcohol, but they must be very strong, as probably the mass, unless it be quite dry, contains a certain quantity of water, and, therefore, if weak solvents were used, the collodion would yield a crapy, and perhaps opalescent, film. If the quantity you have is not large it will scarcely be worth while to attempt to redissolve it. It will be more economical to purchase fresh.

ARCHITECT.—We agree with you that you would be perfectly justified in rejecting the copies. The cause of the distortion at the margins is due to the plans being copied by a lens that was not rectilinear. Probably one-half of a rectilinear was used, as the photographer had not a lens of sufficiently long focus, when used intact, to copy the plans the size required, and therefore employed a single lens for the work.

BACKGROUND.—I want a light background or two for vignettted portraits, only occasionally. Will you please tell me how I can

make them? I may say that I should like a little clouding or shading at the lower portion similar to those sold for the purpose by the dealers. I shall be glad if you can enlighten me, as I cannot at present afford to lay out money.—**IMPECUNIOUS.**

A sheet of brown paper makes a good background for vignettes, and the clouding can be easily done by anyone by simply rubbing on powder colour with a large stump or a piece of rag. Brown paper suitable for the purpose, and about 5ft. wide and of any length, may be had from any of the large furnishing warehouses under the name of "carpet paper." Some of the large stationers also keep it, and it is very cheap. Some is of a grey colour, while other is brown. The grey will be the best for you, if you can get it, but it is not so generally stocked as the brown.

**TOURIST.**—No passport is necessary, nor is a permit to take photographs in Belgium. But keep in mind that you must not take photographs in the vicinity of fortifications—that is not permitted in any country, even in this. You will have no difficulty in getting your apparatus and plates through the Customs. The old towns of Belgium are excellent places wherein to spend a couple of weeks' photographic holiday.

**INVENTOR.**—You are quite wrong. By obtaining a provisional protection you will not be entitled to style your invention "patent" when you put it on the market. If you use the term patent before a patent has been granted you will render yourself liable to a penalty not exceeding twenty pounds. You, however, can use the term "patent applied for" until the patent is granted.

**BREAKAGES.**—I shall feel indebted to you if you will be good enough to enlighten me on the following: I employ several female assistants, and they seem, one and all, very careless. They are continually breaking things—dishes, bottles with solutions, negatives, etc. A week or two ago one upset a measure with about seven shillings' worth of gold solution, just dissolved, and about the same time another smashed a porcelain dish that cost ten and sixpence. I told them they must pay for them, and that I should stop two shillings a week until the amount was paid. This I did last week. On Monday the father of the girl who broke the dish came and demanded the two shillings I had stopped from his daughter's wages, saying that if it was not given he would summon me in the County Court for it. If he does, can he recover?—**S. R.**

We believe he can. Accidents will happen to all, and the employer has to bear the loss, unless he can prove that the damage was wilfully done, or unless he has a special agreement with the employees that they are to pay for all accidents they may meet with.

**TRANSFER OF LEASE.**—I am in treaty for the purchase of a business which is a somewhat old-established one. The present owner of it has a lease of the premises which has nearly two years to run, with the option of renewal for another seven years. The landlord will transfer to me if I buy the business, which I shall do if we can come to terms. The lease is a repairing one, and, so far as I can see, the premises, particularly the studio, are in very bad repair. What I want to know is this. If I take the place now, do I become responsible for the dilapidations already existing, or only those arising during my actual tenancy?—**ONE IN DOUBT.**

If the lease is transferred by the landlord to you, you become liable for the present dilapidations as well as those that may arise during your occupation of the place. This is a fact that you should take into consideration before you complete the purchase, and make allowance for it in estimating the value of the business to you. To maintain old premises in good repair is often an expensive item.

**BURNISHING CARBON PRINTS.**—Please tell me if it is possible to burnish carbon prints, as I have been told it is not?—**CARBON.**

Carbon prints can be burnished the same as other prints, but care must be taken that they are perfectly dry before they are put through the burnisher. Also that they are well lubricated.

**O. P. Q.**—For a studio with the aspect of yours, either dark blue or a rather pale green will be very suitable. The glass may be obscured by stippling over, on the inside, with starch paste mixed with a little whiting. This is preferable to paint, as it can be easily cleaned off when the sunny season is over.

**T. BOWER.**—The reason why so many of your prints go like those sent in so short a time is in all probability due to their being

toned in a combined bath after it has been exhausted of It is for this reason that the combined bath is not to be mended.

**WARDER.**—We have no means of judging if the mounts are of the trouble without submitting them to tentative which we have not time to do. However, they seem to be of quality, and we are not inclined to suspect them, and reason: One of the prints sent, which is yellow, bears unambiguous evidence of imperfect fixation, and others may be like it the evidence is not so palpable.

**OPERATOR.**—If you can see the markings on the plates when they are in the dark slides it is clear that your employer should blame you for the defective negatives. It does sometimes happen that mechanical defects are found in plates, but we must not be misled by such instances as are rare.

**SWINDLE.**—What you say in your letter may be perfectly true, but we have little doubt it is. But we cannot insert it, as your name being appended to it. There is such a thin line between a libel law in this country, and the insertion of your letter, that it is sailing very close to it.

**SECRET PROCESS AND PATENT.**—I have been working a process for four or five years, which I have treated, more or less, as a secret. The method of producing certain results in an easy way. It has been fairly remunerative to me. The other day I showed the whole thing for a small fee, and when I had shown it he said the thing was patented a couple of years ago, and could be stopped from working it in the future. It seems as if I was working the process between two and three years before the patent was taken out, that I shall now be compelled to stop it up. Can you give me advice as to what I can do with the patent?—**HANTS.**

You can do nothing with regard to the patent, and the reason why you should, even if you could. Simply going the process as hitherto, as the patent cannot stop the patentee should attempt to do so, all you will have is "prior use."

**CARBON TRANSPARENCIES.**—I have been making some carbon transparencies for enlarging from, using the special transparent paper. They are all right, except that they are all more or less with peculiar small markings like the one sent. The thing about the marks is that, although they show so when looked down upon, they show little, or not at all, when looked through. Can you kindly tell me how to get rid of them?—**WALTER W.**

The markings are what are generally termed "damp marks," though it is a little doubtful if damp has anything to do with them. Be that as it may, there is a very simple way of getting rid of them. If the transparencies be coated with plain white ink, the marks will disappear, both by reflected and transmitted light.

**R. H. C.**—The collotypes sent are certainly not of a high quality, as the printers allege, may be due to the negatives being by you. It is impossible for any firm to produce good collotypes from inferior negatives. If you have to defend the case in the County Court you must prove that the work is not so bad as the negatives are capable of yielding. If you are a member of the Professional Photographers' Association, it is one of the cases that they can no doubt settle for you without litigation.

\* \* NOTICE TO ADVERTISERS.—Blocks and copy are received to the approval of the Publishers, and advertisements are accepted absolutely without condition, expressed or implied, as to what is the text portion of the paper.

## SUMMARY.

Death of Mr. F. H. Wenham took place on Monday last (P. 617.)  
**NEW METHOD OF SULPHIDE TONING.**—Mr. Welborne Piper has put out a process which allows of the colour given by the usual process being modified with certainty, and without risk of permanency of the result. Formulae and directions are given (P. 617.)

Referring to Dr. Stenger, who has recently made some experiments there is no advantage in using the acid diamidophenol developer with the idea of more safely developing panchromatic plates in ordinary red dark-room light. (P. 617.)

Necessary precautions in regard to making the amidol developer are mentioned on page 614. If too much amidol is suddenly added to sulphite solution the result may be an unworkable developer.

Teaching formula for the bromoil process, consisting of potassium ferricyanide and lead nitrate, has been recommended by the author. (P. 615.)

Methods of travelling photographers undertaking photography at low prices are instanced by the copy of a recent circular from the schools. (P. 615.)

Autochrome filter possessing advantages in Autochrome photography of the patents of the week, which include also a method of developing stereoscopic negatives and of copying from books. (P. 625.)

Port contemporary has recently given some hints as to the photographic trade in South Africa. (P. 625.)

A recent photo-mechanical patent describes a process by which three to print multi-colour prints from a single plate by means of three separate "make-readies." (P. 624.)

Elementary notions as to the use of lenses may be recommended to some of our querists. (P. 622.)

Of the points which stand in danger of being neglected in the use of record and survey photographs are the subject of an article on page 615. The documentary character of such photographs cannot be too forcibly kept in mind.

## EX CATHEDRA.

### Scale Focussing by Touch.

The "Photo-Era," in commenting on the necessity of being able to set the focus of a hand camera quickly and without close inspection of a printed or engraved scale, mentions that a Mr. Julian A. Dimock has patented a device to which he ascribes much of his success with leaping tarpon, wild turkeys, bucking bronchos, angry crocodiles, canoes shooting rapids and other rapid-action work. In his camera the focussing-screw projects through the side of the camera and is controlled by a milled head, which is held between the thumb and middle finger of the left hand. The forefinger rests upon a pointer which projects radially from the milled head and springs lightly into notches cut in a raised disc which surrounds it. As each of these notches indicates a known distance, for which the lens is focussed, the hand of the photographer soon learns to conform automatically to his judgment of the distance of the subject. When, in tarpon fishing, the distances are marked on the line by ribbons, it becomes easy to preserve the exact focus. So, when the fish leaps out of water, the camera is ready for him. The inventor says that often, when birds have flown up near him or fishes jumped unexpectedly, he has turned half round, levelled his camera, and made successful shots while his focussing-hand acted instinctively.

### Permits to Photograph at the Franco-British.

To the recent announcement as to the charge of one shilling per day for permission to photograph at the Franco-British Exhibition may be added the intimation that the office where such permits are obtainable will be found at the Wood Lane entrance just inside the doors, but outside the turnstiles. The small office, where application should be made, will be seen next to the season-ticket turnstile on the extreme right.

\* \* \*

### The Lesson of the Franco-British.

When all the excitement of Marathon races, trips on the Scenic Railway, and so forth has evaporated, there should be a residuum of educative matter in the minds of sightseers who are neither babes nor bloated aristocrats. One walks through all the galleries of art and commerce in the White City, recking little of the impression their contents are making, and perhaps even believing oneself to be just a little bored now and then; but there is a subconsciousness at work busily taking note of everything that enters by the external senses; docketing and pigeon-holing sights, sounds, and smells, whether the outer man, the mere sightseer, will or no. And first of all the prime fact that stands out beyond all others, is that the exhibition as a whole is a marvel, even in these wonderful days. Why is it

a marvel? Because it has the two concomitants of things that reach sublimity, namely quantity and quality. If this great "White City" with all its effects were merely pasteboard, mouths would still open in wonder at its greatness and beauty. Its size would overawe. Mere vastness—as court gives way to palace and palace to garden and garden to the stupendous erections of steel for mere sixpenny rides—constitutes the first impression of grandeur upon the mind. Yet that is only half the effect. Painted pasteboard would leave us at this point, having nothing more solid to offer; but as hour passes hour another impression grows, which is that all this display is superlatively good and lasting considered as a season's exhibition. The common remark is, "Surely they won't pull all this down—what a pity it would be!" Therein lies evidence of the fact that after vastness has done its work comes thoroughness and excellence to call up respect in the beholder. That is the other half which fits the first and makes a complete and complementary impression of sublimity.

\* \* \*

#### The Display of Goods.

There is one great lesson here—namely, if it is desired to make a great appeal to the public, there must be something tangible behind the surface seductiveness. There is brief prosperity in the painting of an enormously fat woman on the outside of the booth if the penn'orth within is only moderately adipose; or to depict a "mermaid" which turns out to be a queer fish, stuffed and smelling of preservative chemicals. The public will desert you if you "have" them. At the "Franco" nobody is disappointed; on the contrary, season tickets are well used. In the matter of display commercial effort has surely never gone further. Firms who have good things to sell have evidently fallen in with the ideas of thoroughness that characterise the place, consequently one is amazed at the taste and skill shown in the very cases and stands of the exhibitors. Especially is this noticeable, on the whole, with the French firms. The Gallic temperament for nattiness and charm of idea has good ground here for exercise. A peep into the Colonial palaces proves that there the leading idea was to include everything appertaining to the colony—to crowd it all in, whether it would be well seen or not. But potted food is poor decoration at the best, and one feels that things less obvious and more interesting might have had more chance had Colonial enthusiasm given them more room. The French exhibits induce none of that embarrassment and revulsion which a clamorous mass of things inevitably does. A few jewels are displayed in a kiosk-like show-case furnished with white leather in flat spaces, wherein are indented little shapes to fit exactly the gems offered to view. With such respect and expansiveness shown to the articles, we are quite ready to believe that their value, as indicated, runs up to as much as twenty-five thousand pounds each. Another firm displays jewellery upon a setting which curves gently outwards from perpendicular to horizontal, and is covered with velvet tastefully graduated and tinted in a stencil pattern, and upon this the jewellery is made the utmost of. But, alas, what dress is all this wealth to the weary spirit! In the interior of one of these priceless stalls one sees a peep of an old lady fast asleep, and a young one on the borders, who slowly raises her heavy lids under the inner conviction that she is caught napping.

\* \* \*

#### Art at Shepherd's Bush.

Something ought to be said of the pictures and statuary also, for surely no other examples of skill should be so productive of lasting impressions in the minds of photographers. The posing of the French sculpture is perhaps too "instantaneous" to offer many lessons to the profes-

sional portraitist. Indeed, it may be said to be accurate and squirmy for the most part. The Gallic temperament is an emotional one, and both in sculpture and painting that which is exciting to the senses seems to supply the motive most often. Clever to the last degree it is undoubtedly; but, in the present collection at any rate, the French has in it less of art for art's sake and more of the literary aspect. Death agonies and the finished furnish favourite motives. But is art, as art (not as telling) any the better for causing us flooded eyes and constricted throats? In landscape the Frenchman is quick and happier. The great Troyon, the little Corots, the pastoral beauty beside the melodramatic griefs of the figure painters. The British section strikes one as being the finest in its more and most modern examples. One of the deepest impressions is of the astounding truth of sun in Friedenson's "Bay" picture. The photographic microscopy of Dice's trees in his "George Herbert" also is in the memory: what appalling painstaking! Another thing that leaves its mark is J. J. Shannon's "Phil Esq." in "pink," whilst his nose and scabs are in crimson. For honest character this portrait outdoes the provoking Cromwell. Two or three other things are borne in upon our minds; one is that the "utter" school of Mid-Victorian times fortunately did not come to stay. The Rossetts here are not the finest. The Burne Joneses invoke for a great unsatisfied Why? The nymphs of Waterhouse, more than sisters even, they are twins, triplets, centaurs, and they haven't a happy look amongst them. Herlihy has for ever left behind him the possibility of doing anything else a quarter as good as his "Last Muster." "The Tide" by Walter Bayes ought to have made a reputation much greater than it is. Sir George Russell, perhaps after all the best of British portraitists, Sargent, whose triple portraits are here in all the astounding perfection of skill, treats his sitters as Walter treats his voice parts: they are only a part of the voice and all dodges of "bringing out," "setting off," "singing to," etc., are swept aside into limbo.

#### The Effervescing of Amidol.

Sometime ago we described a peculiar effervescent effect produced by the addition of stale amidol to a solution of sulphite and metabisulphite. A recent experience with fresh diamidophenol has, however, shown that this effect is due to the deterioration of the developing agent rather than one due to the sudden addition of a large excess of the reagent. The sulphite solution used consisted of one ounce of sodium sulphite and one drachm of potassium metabisulphite in five ounces of water. Usually the amidol is dissolved in this quantity of solution and then five ounces of water are added to bring the total bulk to twenty ounces. In this case only four ounces of developer were required, and, therefore, one ounce of the stock solution was taken, and the diamidophenol was shaken out of the bottle without weighing. As the reagent was a large clotted mass of the reagent, of about the bulk of one ounce of water, fell into the measure. Immediately a violent effervescence and a strong odour of sulphuric acid, though the stock sulphite solution used has the peculiarity of being quite odourless. The resulting solution was strongly acid and had no developing power. By way of experiment, we then added more of the stock sulphite solution so as to restore the approximate correct proportions. The smell instantly disappeared, even though the solution added contained metabisulphite, and on trial the developer worked as well as could be required. Evidently, then, the effervescence and the loss of developing power was due to the excess of diamidophenol and possibly the failures that some workers meet with when using amidol are due to similar causes.

the effect does not take place when the sulphite is added before adding the amidol, therefore if a solution of amidol is required it is best to dilute before adding the dry developer.

**Amidol.** In the current issue of the "Photo-Gazette" there is a note on the use of this paper for the production of the surface ready for printing by the oil process. Although no reference is made to the work of Mr. Welborne Piper, to whom this is due, the writer's object appears to be to prescribe a solution which can be made up without the use of any auxiliary solution. For this purpose he recommends the following:—

Potass ferricyanide .....	5 gms.
Lead nitrate .....	5 gms.
Water .....	100 ccs.

The bromide print fixed and washed is placed in the solution and at the end of about ten minutes bleaches the print to one of faint reddish colour on a yellow ground. No further action is noticed the print is well washed out an hour, during which time the image almost completely disappears, only a few greyish traces remaining. When ready for pigmentation, although, if left some time in this operation, the image returns to an appreciable extent, no doubt owing to the oxidation of the lead salts in the light. M. Coustet advises that after pigmentation the print should be fixed in hypo in order to remove all the lead and silver salts and prevent subsequent darkening of the image, but it is thought that if sufficient washing after printing has been given there should be no need to make this the hypo bath at the risk of damaging the pigment. A writer in the "Photo-Revue" has exposed an oil print for a whole day to sunlight without any fading of the image taking place.

**Development.** A week or so ago we published details of a patent taken out by P. L. V. Gaultier, of Versailles, for what amounts to the oil printing to photolithography. Briefly it is made on paper coated with gelatine and inked with bichromate. After washing it is inked with litho ink, applied by a roller, and then the image is transferred to stone or zinc. Up to the present stage it is literally the oil printing process described by Mr. Rawlins, even the inking process by roller being new, while the idea of transferring the image to stone is one that has been suggested and experimented upon before. When litho ink is used it is easy to produce a duplicate of an oil print by simply rolling the print in contact with a sheet of plain paper. We have experimented on these lines, and by re-inking the print we have produced several copies. Whether the process is to be used on stone has proved practically useful or not is not known, but the idea is so obvious that it has already been tried by photo-engravers.

**Photography.** When sufficiently fine solid particles are suspended in a liquid, careful examination under a high-power microscope shows that the particles are in rapid motion, the motions being styled "Brownian" from the name of their discoverer. According to Einstein's theory regarding these movements, they should vary in velocity as the square root of the absolute temperature, the truth of the theory is not very easily tested on account of the difficulty of measuring the motions. Dr. J. J. Diddig has called in the aid of photography to test the theory. By taking two photo-micrographs at an interval

of 1-10th second he was able to measure the movements. It is stated that a falling shutter was used with two holes, which gave two 1-40th second exposures 1-10th second apart. Apparently both exposures were made on the same plate, and the measurements were made on enlargements. The material studied was cinnabar suspended in liquid and allowed to stand for a week. A drop of the top layer of liquid was then used for the experiment. It appears that the results served to confirm Einstein's theory. If it is possible to secure photographic trails of the movements similar to star trails, it appears to us that rather more definite results should be obtained, as the whole course of the movement could then be measured, whether straight or curved.

### Scholastic Photography at 2d. a Time.

A particularly choice specimen of the circulars by aid of which the travelling photographer plies his trade may be reproduced here as showing the lamentable cheapening of the photographic portrait by persons who, if we may judge from their command of the language, are not drawn from the flower of the English race:—

#### NOTICE TO PARENTS.

We beg to inform the Parents of the scholars that with a view to the formation of the Photographic Scholastic Tableau, our operators will, on their visit, gratuitously photograph their children separately or in groups with their brothers and sisters, and we therefore beg them to have the kindness to dress their children suitable for the occasion.

We on our side, in appreciation of the parents' kindness in this regard, have decided that the pupils who bring on the day of the operation the simple sum of 2d. will receive the simple proof of their personal photograph, similar to that which will be provided for the Scholastic Tableau.

The families who might desire to receive this proof perfectly finished, mounted and retouched, will only have to pay on the day of the operation the simple sum of 4d., that is to say just the price of the workmanship. The parents can also have these photographs in larger size on Postcards at the price of 1s. 8d. per ½ dozen and 2s. 3d. per dozen.

The parents have, therefore, every interest in availing themselves of this exceptional occasion. The photographs delivered are unfading.

Such work as this has to be done by over-worked, under-paid help, and this feature of it, we fear, supplies the best ground on which a local photographer can enlist the sympathies of his townspeople in his struggle against such competition.

### RECORD AND SURVEY PHOTOGRAPHY.

It should be said at the outset that no disparagement is intended of the unselfish and invaluable services already rendered by the various photographic survey associations, if some slight suggestions are offered in the direction of making their work still more systematic, effective, and permanently useful.

These associations are formed for a definite purpose. They exist avowedly to preserve for posterity a clearly pictured presentment of the architecture, antiquities, topography, and customs of our own times, together with other facts of scientific interest, and to prevent any avoidable loss of useful historical material. A second aspect of such collections of photographs is their utility for present-day reference. From numerous prints to be noticed in county museums, and from the inspection of various local exhibitions of record photographs, it would appear that the primary intention which should underlie such work is not always kept strictly in view.

One reason for this is the influence of pictorialism. In record work the pictorialist is at a disadvantage. If he would succeed in this direction he must throw overboard all his cherished ideals of composition, and be content to proceed in an unblushingly realistic and matter-of-fact

way. Many prints miss being satisfactory records solely because their producers have failed to divest themselves of their pictorial prepossessions. As an example, met with at a recent county survey exhibition, an ancient church with a curious lych gate had been photographed from a standpoint some distance away, looking down a leafy avenue of trees whose branches met overhead in a sylvan arch. Here, in consequence of the worker's unwillingness to lose a pleasing setting, the real objects of interest—the church and lych gate—were shown on a small and unconstructive scale, besides being partially hidden by foliage.

To quote other instances that will no doubt have been noticed by those familiar with the usual run of survey photographs, we find quite frequently that places of interest, such as cathedrals, castles, old cottages, etc., are allowed to take an entirely subordinate and distant position in their respective pictures, while an enormous amount of foreground space will be occupied by an attractive rendering of a flower garden, a vista of altogether commonplace cabbages, or even an expanse of bare open common. This, of course, is entirely due to the pictorial aspect of the work having been permitted to overshadow its practical side. It needs no argument to see that one flower garden is very much like another; that cabbages are scarcely liable to great variation as the ages pass, still less to ultimate extinction; while a stretch of undulating grass certainly presents no features worth transmitting to posterity. The sole excuse, from a record point of view, for taking the photographs was to show the respective buildings, and this could have been done much more effectively by getting closer, and ignoring the uninteresting surroundings. As it is, posterity will only be able to peer through magnifying glasses at the softened outlines of far-off spires, roofs, or battlements, as the case may be, while marvelling greatly at their predecessors' apparent lack of foresight.

Recalling some more random recollections of survey prints, an extremely picturesque rendering of a beech wood with sunlight streaming through and across the tangled branches might not be at all out of place at the R.P.S. exhibition, but is of doubtful value otherwise; the banks of rivers and streamlets with reedy or rush-covered foregrounds; roadside ponds with trees and reflections; heaths and furzy commons, are things little likely to vanish from the face of the earth, and of no urgent necessity as records. These remarks must not be taken as condemning those photographs which show some distinctive natural feature or unusual physical configuration of any given locality. These come in quite a different category and are well within the scope of record work.

Church interiors are favourite subjects, and it is curious to see how often the worst point of view is chosen, from an architectural or ecclesiastical standpoint. There are comparatively few churches in which the west end is more worthy of record than the east or chancel end, yet in quite a number of cases we find that the lens has been pointed away from the chancel, to obtain a view of a perfectly blank west end and a long perspective of ugly modern pews or chairs, while ignoring in all probability a beautiful and richly decorated sanctuary with elaborate windows. Even where the west end is deserving of special attention, as having an ancient singers' gallery, font, canopy, or other notable features, the chancel will most likely possess attractions of its own, and should be taken also, if possible, at close quarters. Details as to the altar furniture and church decoration of bygone years are sure to appeal to future generations. With regard to windows, why are these so frequently depicted as a mass of white, devoid of their delicate tracery and wealth of embellishment? The advantages of backed plates seem to be ignored by a very large number of workers.

The supreme importance of detail in record photographs

cannot be too strongly insisted upon. Any lack of detail is a serious drawback to the utility of the picture. Nevertheless, a casual examination of the average collection will disclose many prints which verge perilously on fuzziness. We see photographs of interiors, evidently taken with a large aperture, in which near objects are sharp, while those in the background are quite out of focus. Whether done with pictorial intention or not, is a fatal error, for a record print should show everything that is to be seen—ugly or otherwise. With such subjects the lens should be sufficiently stopped down to get all the different planes in focus, unless there is a difficulty at the time of exposure required. Inexcusably light prints, which means lack of detail in another guise, is not so as it should be.

With architectural and archæological subjects it is a mistake to include too much in the picture. A single object or detail treated by itself, on a recognisable scale, is of more value than a profusion of ornament so small and jumbled together that no definite impression is conveyed, or many objects which the eye tries in vain to separate from each other. Clear, distinct photographs of ornamental or decorative detail have a genuine value, especially if, as seems to be very seldom the case, they contain something that will give an indication of measurement or scale.

One would like to see greater attention paid to classification, grouping, and indexing. At present a number of photographs dealing with the same place or subject sometimes be found separated from each other, and require much trouble to gather together for examination, even if the necessary clues as to their existence can be obtained from the index. Key photographs indicating relative positions occupied by various portions of a subject which has been taken in sections, and small photographs pointing out the standpoints from which different portions of an identical place or object have been secured, might in many cases be prepared with advantage.

If our record and survey collections are to be really useful, both now and hereafter, easy of reference, and free from an overwhelming embarrassment of irrelevant material, steps will probably have to be taken to define more exactly what a record photograph is, or should be. Attention might be drawn more frequently to those things which are really worth recording, and of which so few photographs are extant; especially to local events and happenings likely to be of historical, antiquarian, or scientific consequence. The argument from analogy can be profitably applied. Let us ask ourselves what kind of pictures or documents we should be most grateful for, if our ancestors had possessed similar means of leaving them. In all probability the answer to this question will tell us at once the kind of record that we may most usefully make.

---

**OIL AND BROMOIL PRINTING.**—The booklet by M. R. Demachy and J. A. Sinclair, recently published at the request of the latter's firm, Messrs. J. A. Sinclair and Co., 54, Haymarket, London, having completely run out of print, a new edition is now in preparation. It will contain also the necessary instructions for the "Bromoil" process in the shape of an article by Mr. C. H. Heath. The booklet will be ready by the time these lines appear, and application should be made to Messrs. Sinclair for it. Price 6d. post free.

**THE CURRENT ISSUE OF "The Prism,"** which is now issued in an enlarged form, deals with the subject of field glasses, with special reference to the Zeiss Stereo. The article is well illustrated, and of its subject in a popular and interesting manner, and may be obtained, by sending a penny stamp to cover cost of postage, to Messrs. A. E. Staley and Co., 19, Tavistock Inn, Holborn, London, E.C.

# NEW METHOD OF CONTROLLING THE COLOUR IN SULPHIDE TONING.

Formulae for the sulphide toning of bromide and gaslight prints have been multiplied a good deal of late, but without one being produced which is an actual practical improvement on the now generally used mixture of potassium ferricyanide and ammonium bromide. In the following article, however, Mr. Welborne Piper describes a new departure in sulphide toning which should provide the much-needed means of making modifications in the tone given by the usual process. It possesses the commendable feature that it does not involve the use of mercury salts, or other substances which vitiate the undoubted permanency of prints toned by the sulphide process pure and simple.—Eds., "B.J."]

It is now a recognised fact that the brown image produced by sulphide toning is not composed of simple silver monosulphide, but is a colloidal compound soluble in hot water. From this it may be argued that the exact colour obtained should be more or less under control, and could find any way of either hindering or accelerating the formation of the colloidal compound, and an obvious experiment is the hardening of the gelatine before the toning process. Tests, however, show that hardening agents such as chrome alum or formalin have no effect on the colour; therefore I have recently turned my attention to the use of reagents that have a special hardening action on the gelatine in the vicinity of the silver image. I tried the usual solution as a bleach, but with no success. If anything, the resulting tone was inferior to that produced by ordinary methods. I tried preliminary baths of bichromate, with numerous variations in the time of immersion and duration of washing, and followed by various bleaching solutions, but still the modifications obtained were only trivial, and no real improvement was effected. In these experiments, however, I noticed that there was often a difficulty in getting the print after a preliminary soaking in bichromate, especially when the bichromate was not washed out, and to get over this I added a soluble bromide to the bichromate bath. After preliminary soaking I added ferricyanide to the bichromate and the bath, and so turned it into a bleacher. The final result was rather astonishing, for it turned out to be a quite cold tone, or just the colour I had been aiming at all along. Numerous subsequent experiments show that the bromide in the bath is essential to the effect, and so possibly the final result is due to the action of bromine on the gelatine, for it is well known that bromine water used alone as a bleach gives a rather stronger tone than the ordinary bleaches, and also that bromine gives an insoluble precipitate in gelatine. The exact final tone obtained by the new process varies with the time of preliminary soaking, and the result is perfectly under control. After testing many variations, I have fixed on the following as the best procedure to follow.

1. Soak the bromide print in water until limp, and then immerse in the following solution:—

10 per cent. ammonium bichromate ..... 5 oz.  
10 per cent. ammonium bromide ..... 5 oz.

2. The print must be kept rocking during this immersion, otherwise uneven markings will result, and to produce a cold sepia the time of immersion must be six minutes. Shorter periods give intermediate tones, but six minutes give as cold a tone as seems to be desirable. When the print is soaking, prepare for the next stage by taking 10 oz. of 10 per cent. potassium ferricyanide solution and adding to it

2 drachms of ammonia .880. It is desirable to have this solution in readiness, as it is unnecessary to wash between the soaking and bleaching of the print.

When the time is up, pour off the A solution and add to it the solution of potassium ferricyanide. Rinse the print once or twice in water, and then bleach it in the modified solution. The result is not very light coloured. It is a fairly strong brown, but the action can be considered to be complete when the last trace of blackness has disappeared. Next, wash in running water for about ten minutes, and then tone for five minutes in a 5 per cent. solution of sodium sulphide. Pure sulphide from a reliable manufacturer should be used, but it does not appear to matter whether it is of the crystalline or fused variety. The former gives a very slightly colder tone than the other, but that seems to be the only difference.

The bromide prints should be fairly strong ones, and the best results seem to be obtained from clean vigorous negatives of the kind suited to P.O.P. This appears to be the case in all kinds of sulphide toning, but, so far as I know, no kind of negative will give by the ordinary process a tone that approaches the one obtained by the new process, excepting on a few exceptional brands of paper.

The method as described is suited to the preparation of one print. If a number have to be toned I simply make up two separate solutions. One according to the formula A already given for the preliminary soaking bath, and a second one for bleaching. The formula for the bleach is then:—

B. 10 per cent. ammonium bichromate ..... 5 oz.  
10 per cent. ammonium bromide ..... 5 oz.  
20 per cent. potassium ferricyanide ..... 10 oz.  
Ammonium .88 ..... 2 drms.

Solution A can be used for a number of prints in succession. B will lose power in time, and will then have to be re-mixed, but it will serve for a long time if the prints are rinsed very slightly before bleaching. Apparently it is necessary to use a bleach of this or of very similar composition, and the bichromate in B seems to be quite as important as the bromide in A. Why is not clear. The mechanism of the process is undoubtedly obscure, but in spite of this the results seem to be very certain, and the tones obtainable are of a very desirable kind.

The bleaching the print takes about two minutes. An alternative bleaching bath is obtained by adding 20 minims of strong nitric acid to 20 oz. of A solution. The final result is then a very rich brown tone, approximating to a warm sepia, when the preliminary soaking in A is six minutes. We can thus obtain either warm or cold sepia as desired, the exact colours varying with different brands of paper.

C. WELBORNE PIPER.

# THE ACID DIAMIDOPHENOL DEVELOPER FOR ORTHOCHROMATIC AND PANCHROMATIC PLATES.

In the current issue of "Photographische Chronik" the much-discussed question as to the effect of an acid amidol developer in depressing the red-sensitiveness of an orthochromatic plate to such an extent that development can be done in the ordinary dark-room light is made the subject of a contribution by Dr. E. Stenger, of the Charlotten-Technical High School. Dr. Stenger's experiments, of which the following is an account, were made in order to test the statement made by various writers as to this destruction of colour-sensitiveness, depression of general sensitiveness, and the effect of the developer to make good considerable errors in exposure.—Eds. "B.J."]

As the numerous colour-sensitive plates on the market to experiments of this kind might be applied, two brands were chosen on account of their widely known properties—viz., the "Perotto" green label plate and the "Perchromo,"

both made by Otto Perutz in Munich. These were selected on the natural assumption that orthochromatic and panchromatic plates from other sources would behave similarly. It was only in regard to the time of development that differences were dis-

covered (when developing with amidol) between different brands of plates. According to H. Reeb, all plates are not equally well suited for amidol development, as dichroic fog is apt to make its appearance when an excessive time of development is adopted, but in the following experiments a normal period has been the rule.

Simmen gives the following formulæ for the use of amidol:—

I.—Acid amidol developer, slow working.

Amidol .....	1 gm.
Sodium bisulphite liquor, commercial .....	4 ccs.
Sodium sulphite (anhydrous) .....	3 gms.
10 per cent. potass. bromide solution .....	2 ccs.
Water .....	100 ccs.

II.—Amidol developer of quicker action for under-exposed plates.

Amidol .....	1 gm.
Sodium sulphite (anhydrous) .....	3 gms.
10 per cent. potass. bromide solution .....	1 cc.
Water .....	100 ccs.

The acid amidol developer recommended by Balagny for Autochrome plates has about the same composition as Formula I. above. The acid sulphite solution of commerce is prepared, as is well known, by conducting sulphur dioxide gas into sodium sulphite solution. It is a yellowish strongly acid liquid with the characteristic smell of sulphurous acid, and contains sodium acid sulphite. The solution used in the following experiments had the specific gravity of 1.33 = 36 Beaumé.

Each test plate of the size of 9 by 12 cm. was exposed behind a paper scale photometer, and then cut into three portions, which were developed simultaneously under different conditions, fixed together in the same bath, and, after drying, measured in the Martens polarisation photometer. The paper-scale photometer consisted of strips of tracing paper, the transparency of which was such that exposure through any given portion had to be one and a half times as long as through the next denser portion in order to give equal densities. The relative times of exposure and the corresponding logarithms, as used for the graphical representation of the densities, are given in Table I.

TABLE I.

Number of layers of paper	12	11	10	9	8	7	6	5	4	3	2	1	0
Exposure number .....	8	12	17	26	39	59	88	132	198	296	444	666	1,000
Log $t : t_0$ .....	0.90	1.08	1.23	1.41	1.59	1.77	1.94	2.12	2.30	2.47	2.65	2.82	3.0

Experiment I.—Of the three sections of a "Perotto" plate (green label), the first and second were developed in rodinal, 1 in 20, the third in acid amidol, in each case for four minutes. Sections 1 and 2 were exposed during the whole time of development to the red dark-room light, whilst section 2 was developed in the dark. The dark-room light was purposely chosen fairly bright, and consisted of rays of wave-length from 640 to 720  $\mu$  with some green rays, and was placed at a distance of about 50 cm. from the plate. The development fog in the unexposed portions of the various plates was as follows:—

Rodinal used in dark-room light, .66.

Rodinal used in the dark, .48.

Acid amidol in dark-room light, .39.

The fog value is thus smallest in the case of acid amidol, but the measurements show that the time of development of four minutes is not long enough for the amidol developer employed. The plate could do with one and a half or twice as long in order to obtain the same density as that produced on the plate developed with rodinal. A portion of a plate, however, which was given six minutes in acid amidol developer showed, in the unexposed portions, a development fog of .51, which is more than that of the plate developed with rodinal in the dark. The value, however, of the plate developed for six minutes in amidol did not amount to so much as that obtained in four minutes with rodinal. In the case of equal densities for both developers the fog value was still more unfavourable to

the amidol-developed plate. This experiment shows that under the above conditions there is no advantage in employing acid amidol developer for orthochromatic plates. The graduation curves given in Fig. 1 show graphically the relative ad-

of the three developers, and correspond to the data given in Table II.

TABLE II.

Exposure numbers.	Log $t : t_0$	Densities.		
		Rodinal 1:20 4 minutes.	Acid amidol.	
			4 minutes.	6 minutes.
12	1.08	1.30	0.80	1.13
17	1.23	1.48	0.98	1.27

59	1.77	2.18	1.42	1.80
88	1.94	2.28	1.65	1.94
132	2.12	2.58	1.83	2.24
198	2.30	—	1.98	2.41

Experiment II.—A "Perchromo" plate (ethyl red emulsion) was cut up and developed on the one hand for four minutes in 20 rodinal with and without exposure to the dark-room light, and on the other hand for six minutes in acid amidol developed in the dark-room light. The development fog on unexposed portions was as follows:—

Rodinal in dark-room light, .93.

Rodinal in the dark, .61.

Acid amidol in dark-room light, .86.

Here again it was seen that the acid amidol proved of no advantage, as the fog was only very slightly smaller than that obtained with rodinal when using the ordinary precautions necessary in developing panchromatic plates.

Experiment III.—This experiment corresponded with the foregoing, with the exception that during the first two minutes of development with the acid amidol the plate was kept covered in order to give the solution time to exert its destroying action upon the sensitiveness (colour and general) of the plate. The fog values in this case were as follows:—

Rodinal, 2 minutes in dark, 2 minutes in dark-room light, .93.

Rodinal, 4 minutes in dark, .58.

Acid amidol, 2 minutes in dark, 4 minutes in dark-room light, .92.

This experiment is most unfavourable to the acid amidol developer, the fog being actually more, in spite of the shielding of the plate during the early part of development. In order to throw a light on the behaviour of the amidol developer during more protracted time of development the next experiment was made.

periment IV.—It was found that the protracted development is not really responsible for the extra fog. The test was as in experiment III., except that the third portion of the plate was given first two minutes in acid amidol developer and two minutes in the quicker acting amidol developer, No. 2, in both cases in the dark. The following were the results. Rodinal, 2 minutes in the dark, 2 minutes in dark-room light, .77.

Rodinal, 4 minutes in dark, .62.

Amidol I. and II., 2 minutes in each, in dark, .80.

The amidol plate thus gave, in spite of the use of the powerful developer, less fog than the plate treated with rodinal. It appears to be an error in the figures given by the author, amidol fog being .03 in excess of that given by rodinal.—“B.J.”]

periment V.—The depressing action of the acid amidol developer is to be ascribed, as stated by Simmen in the case of the chrome plate, to the acid sulphite contained in the solution. As therefore thought possible that a preliminary bath of sulphite would exert the desired action on the sensitive plate. For this purpose the ordinary commercial acid sulphite solution was diluted with ten times its volume of water, the plate developed therein for two minutes, then washed in the dark, and developed along with a second portion of plate which had

been washed for three minutes in the dark in 1 in 20 rodinal for 4 minutes in the dark-room light. The following were the results:—

Plate treated with sulphite solution, 1.06.

Washed and developed plate, .96.

Also when used in this way the acid sulphite is seen to give a slightly worse result than when it is omitted. The densities in both plates were the same as shown in Table III.

TABLE III.

	Fog.											
	Plate density for log $t/t_0$											
Plate after sulphite bath ...	1.06	0.98	1.05	1.16	1.25	1.36	1.44	1.69	1.85	2.00		
Plate after water bath .....	0.96	0.97	1.09	1.18	1.27	1.35	1.47	1.73	1.87	2.05		

It should be noticed that ethyl red, the sensitiser of the “Perchromo” plate, appears to be comparatively resistant to weak or strong solutions of acid sulphite. Aqueous solutions were decolorised only very slowly. “Perchromo” plates in the dry state, when placed in weak or concentrated sulphite solution, lost their colour more quickly by simple bleaching out in light than through the action of the acid sulphite. The unfortunate result of the experiments is therefore to show that for the development of ordinary orthochromatic or panchromatic plates acid amidol gives only negative results.

DR. E. STENGER.

## NOTE ON THE RELATION OF ASTRONOMICAL SECONDARY NEGATIVES TO THEIR ORIGINALS.

[A Paper in “Popular Astronomy.”]

The use of glass positives is a matter of every-day practice in the preparation of plates recording astronomical (and physical)

outlying nebulosity farthest removed from a nucleus, or other detail of low relative contrast, then it is the general practice to resort to local (chemical) reduction on the film of the positive.

There are, however, negatives of certain subjects in which it is not possible by this single remove to introduce sufficient contrast to clearly show the structure which can be traced with a practised eye, upon the original negative. In this event, it is necessary to make from the original a secondary negative,

Fig. 1.

These positives are in many instances made directly from the original negatives, and, where the object is to direct attention to fine filamentous structure or detail, such as the

Fig. 2.

in which, by the minimum of exposure and the maximum of development (together with judicious chemical reduction), the relative contrasts are exaggerated. By such means one is enabled to render visible in the positive or subsequent engraving those particular characteristics which would otherwise remain merely records apparent to the eye of the individual privileged to examine the original negative.

It must, however, be evident that no matter what care is

taken, or how expert an individual may become in the handling of copying processes or reducing solutions, used either locally or in "flat" reduction, the resultant positive cannot but (under the circumstances) be utterly false in its relative photographic light values. The result is, that except for "form," the new negative or positive is neither a record of visual nor photographic relative intensity.

Further advance along the line of photographic plates does not promise a betterment of these conditions, because no matter

be suggested. This is more particularly the case where a photograph purports to be a record of scientific accuracy, in which relative photographic intensity holds a prominent place.

The alteration in the ratios existing between the densities of a photographic negative due to chemical reduction, was pointed out definitely in the classical research of Hurter and Driffield;<sup>1</sup> it is desirable, however, that a record be obtained embracing the gradual action of the reducer upon the p

Fig. 3.—Black Hole in Milky Way. (R. A. 19h. 38m.  $\delta$   $10^{\circ}46'5''$ .) Change in relative light-values with increase in contrast.

Fig. 4.—Black Hole in Milky Way. (R. A. 19h. 38m.  $\delta$   $10^{\circ}46'5''$ .) Change in relative light-values with increase in contrast.

how much they may be improved, or rendered more adaptable, there will always be nebulous structure, or faint lines, which lie at the extreme limit of the under-exposure portion of the characteristic plate curve, while astronomical negatives continue to be made.

Under the assumption then, that conditions in this direction indicate a fair degree of stability, it is advisable that some method of estimating the change in the photographic light value between the later illustration and the original negative

under conditions approximating actual use in astronomical work. A negative was therefore made by development of exposure in the revolving sector-disc machine, and after measurement in the spectrophotometer its curve was plotted. A standard reducing solution<sup>2</sup> being then made up, the plate was placed therein, and rocked for 2 min. 30 sec.; it was then

<sup>1</sup> "Journ. Soc. Chem. Industry," May 31, 1890, p. 462.

<sup>2</sup> Potassium ferricyanide and sodium hyposulphite in proportion of 1:10,200 combined solution used at a time; size of plate  $3\frac{1}{4}$  by  $1\frac{1}{4}$  inches.

ashed, dried, and again measured and plotted. Subsequent reductions and measurements were now given in three steps 2 min. each, followed by two further reductions for 3 min. each, and one action for 5 min. The reducing solutions were made up fresh for each operation, and the film was always washed and dried before measurement. The resultant curves are shown in Figure 1, where the heavy continuous line indicates the original negative, and the dotted lines show the action of the reducing solution for the times indicated. The appearance of the lower densities will be readily marked. If there should be placed in position adjoining the original supplementary small negative containing a scale of densities, this scale-plate be impressed on all subsequent copies, negative or positive, undergoing precisely the same treatment does the body of the plate, then the measurement of the scale upon the last plate of the series will, in conjunction with the original, give a difference which represents the value of the photographic light change.

Calling the densities of the original  $D_1$ , and those of the

Examination of these resulting negatives showed a wide difference in relative contrast and density, which was further accentuated by reduction with ferrieyanide and hypo. Absolutely no local reduction was given, but the action of the solution was allowed to proceed evenly upon the respective plates, and, of course, acted equally upon the adjoining scale-plates. The inclusion of positive plates  $e, f$  (which are exposed and developed to reproduce as exactly as possible tones truly the inverse of those in their accompanying negatives), merely serve to illustrate the values obtained.

From measurements of the original scale-plate, and also of that resulting in the secondary and tertiary positives, the accompanying curves were plotted, Figure 2. This method of plotting was first suggested by Hurter and Driffield,<sup>4</sup> wherein the ordinates represent densities of the *positive*, while the abscissæ correspond to the *negative* densities. As is obvious (and pointed out by these investigators), if the positive densities be truly the inverse of the negative, then the curve would be represented as a straight line. The amount of departure

Fig. 5.—Black Hole in Milky Way. (R. A. 19h. 38m.  $\delta$   $10^{\circ}45'5''$ .) Change in relative light values with increase in contrast.

the negative after reduction  $D_2$ , then the change in the ratios is tabulated thus:—

	$D_1$	Ratio.	$D_2$	Ratios.
...	1318	.....	.....	.....
...	3086	.....	.....	.....
...	5624	1.0	0780	1.0
...	8720	1.55	2736	3.51
...	12800	2.27	5454	6.99
...	18554	3.30	9906	12.7
...	26354	4.69	15184	19.5
...	53956 (?)	9.57	20644	26.5
...	.....	.....	24954	32.0

the densities of the reduced negative proportional to the original, then the ratios would be similar no matter what the values of the densities.

Referring to the actual employment of the method, there is shown in Fig. 3 (a), the original negative<sup>3</sup> and the original plate, together with a positive reproduction of the same. From this positive were made the secondary negatives  $d$  and  $e$ . For the production of negative  $c$  a Seed "23" plate made use of, while negative  $d$  was made upon a Cramer transparency plate, being pushed to the practical limit of its action.

from the straight line condition indicates the value of the difference.

So long as this method of reproduction is utilised, then, tremendous shortening of the tone-scale will inevitably follow. Making use of a different type of reducing solution (ammonium persulphate, for example) is not allowable on work of this class, because one should then undo a very considerable amount of the effect which was striven for in the exposure and development of the subsequent plates from the original—viz., increase in the under-exposure portion of the characteristic curve of the plate. We are purposely and intentionally altering the tone-values because it is just that alteration which is desired. It remains, however, that it would seem advisable that there should be some means of indicating just what change has taken place in the light values, and it follows that such change should be capable of expression, and, further, that every illustration serving as a record of scientific data which is printed from other than the original negative, should bear in such reproduction a copy of a tone-scale showing both the "before and after" effects, and thus point the way for correction to true values when the knowledge of such values is needful.

ROBERT JAMES WALLACE.

Thanks are due to Mr. F. W. Jordan for the use of this negative.

## SOME DISCURSIVE NOTES ON LENSES.

It appears to me, judging from the replies I am constantly seeing in the "Answers to Correspondents" column, there are many amateurs, as well as some professionals, who do not seem to understand—even superficially—the properties of the tools they employ. It is for this reason I venture to pen the following few notes. This I propose to do in such a simple way that they may be fully understood by those who have no knowledge of optics. Notwithstanding all that has been written in the form of replies in this and other journals, there are evidently many who are still ignorant on several points, and I am therefore warranted in assuming that some misconceptions exist on the subject.

### Angle of View.

One point that occurs to me is the query, often repeated, with reference to wide angle, medium angle, and narrow angle lenses. It does not seem to be understood by every one that one and the same instrument may combine the whole of the three properties, and may be serviceable for all of them. A wide angle lens, it may be explained, is simply one that will cover a large plate, although its focal length is but short. For example, lenses are made that will include an angle of 90 deg., and even more. The largest aperture of a wide angle lens proper is about  $f/16$ , but if the full size of the picture which they are listed to cover is required to be quite sharp to the edges of the plate they may require to be still further stopped down, when, of course, they will become very slow in action. I need not here dwell on the fact that no experienced photographer would think of using one of these lenses at its full capacity except on extreme occasions—in very confined situations, interiors, and the like. He would not use such an instrument if he could use a longer focus one, getting further back, so as to include the same amount of subject, and for this reason:—With the very short focus one, the perspective, though strictly correct, would be violent, and, consequently, very displeasing.

It has just been mentioned that the same lens may be a wide angle one, a medium angle, or a narrow angle one, a statement which may require a little explanation. Let us suppose we have a wide angle lens, made to cover, say, a  $10 \times 8$  plate. Such a lens will have a focus of about  $5\frac{1}{2}$  in., but if we use it for a quarter-plate it then at once becomes quite a medium angle one, and the angle then included will be about the same as we get when using the ordinary "quarter-plate" lens, the angle included being less than 50 deg. If this same lens be employed for a still smaller plate than the quarter size it then becomes a narrow angle one. The disadvantage of employing what is supplied as a wide angle lens as a medium or narrow angle one is that by reason of its small fixed diaphragm it cannot be used for rapid work. The rapid rectilinear lenses of our best makers will, when stopped down, cover a plate the next size larger than that for which they are listed, and with still more stopping down, often two sizes larger. This is particularly true of anastigmat lenses. When so employed they become more or less wide angle lenses.

The angles included by lenses of different focal lengths, on different size plates, do not seem to be so well understood by many as they might be. If the base line of the picture is equal to the focal length of the lens, the angle included is 53 deg. If it measures one and a quarter the focus, the angle is 64 deg. If one and a half it is 82 deg., and if it is twice the focal length the angle included is 90 deg. It therefore follows that when it

is necessary to include this angle the lens must be capable of covering a plate the base line of which is twice its focal length, and when such a lens is used one must, without a moment's consideration, expect to get violent and unpleasant perspective, which is frequently looked upon as being "distortion," although it really is not, for if the picture be viewed at a distance equal with the focal length of the lens, no so-called "distortion" will be seen.

### The Single Lens in Modern Work.

Of late years very little has been done with single lenses, many seem to be under the impression that to obtain good results a double or compound is indispensable, as, indeed, they are, if very rapid exposures are necessary. It is true that one of the components of a compound, say of a R.R., is sometimes used as a single lens, but it requires considerable stopping down in order to get good definition over a moderate size plate. Some of our old workers rightly tell us that for pure landscape work no equals the old form of single landscape lenses that have disappeared to be made for some few decades now. These are quite difficult to construct from the single lenses of a R.R. compound. They are of deep meniscus form, whereas the former are plano-convex, and much larger in diameter, in proportion to their focal length, and they do not require so much stopping down, consequently are quicker in action. These, as made by the late Mr. A. Ross, have an aperture of about  $f/15$ , at which aperture they will cover well the sizes listed. This aperture seems to be nowadays, but if enlarged to  $f/11$  the lens still gives fair definition.

The original form of landscape lens is really very useful for general purposes—much more so than many think, and sometimes be met with for about as many shillings as its original cost pounds. There is a prejudice against single lenses because they do not give straight lines in the picture, but this is not apparent when, say, the lines of a building are shown at extreme edges of the plate, and not otherwise. For instance, two straight lines, at right angles to each other, be photographed in the centre of the plate, even if it be the full size, neither will be in the slightest degree distorted. These old instruments, with their full aperture, are excellent for outdoor group work, on reason of their comparatively great depth of focus. It may be thought by some that, by reason of the small fixed diaphragm they would be very slow, but in practice they are not so. For example, we employ, say, a R.R. for a group, it has to be stopped down to about  $f/16$ , or less, to get figures in different planes in fair focus. With this aperture the R.R. is really the slowest of the two, as it has four reflecting surfaces, while the single lens has but two. I know an experienced photographer who always uses the old form of landscape lens for outdoor groups in preference to any other. I also know a firm that do a good deal of copying that always employ these lenses for copying small pictures, as the operators find that with them they get more brilliant negatives than with compound lenses. Of course, they take care to use only those of long focus in proportion to the size of the pictures to be reproduced.

These elementary notes on facts which must be perfectly familiar to many readers of the "Journal" will, it is hoped, be of service to the many whose acquaintance with photography is but short, and whose knowledge of the tools of the old days which can still be used with advantage is necessarily slight.

H. M. PELWIT

**CINEMATOGRAPH FIRE.**—During a matinée performance of a cinematograph entertainment in Hengler's Circus, Glasgow, last week, a film caught fire. An explosion followed immediately, the flames

shooting up as far as the side galleries, and causing great alarm. The manager assured the audience there was no danger, but it left the building

## GOODS READY WHEN PROMISED.

If we believe our contemporary the "Bulletin of Photography," the American professional needs to be moved by satire to see the swiftness of his ways, as witness the following cartoon (with apologies to George Ade) and letterpress. The article suggests that with all we hear of the "go" of a few American photographers, the rank and file are not on a level with their fellows in Europe.—Eds.

Upon a Time a certain man wished to get Rich Quick because he needed the Money to Put into the Bank. Opportunity Knocks once at Every Man's Door," said He, "and make sure She doesn't miss me. I'll sit up and answer the Bell." He waited nearly twenty minutes, but She didn't come. "No more," said he. "So I'll go out and look for Her." He looked around briskly and saw a Vacant Lot.

Finished product would be Ready the Day it was Promised. People set their watches by the way Goods were Ready. The Photographer was as Sure as the Seven o'clock Whistle.

His fame travelled fast. People came all the way from out of town to Patronise him. One man came all the way in from Evanston on the L. And that's going some. Some time. The Illinois Central built a special Track to the Studio.

At last," he exclaimed, "my search is ended. My efforts are rewarded." With these words he built a Photograph Gallery, or Studio, as the name may be, and hung out a sign saying that all goods would be ready when promised. It revolutionised the Photograph business! People were aghast at the novelty! When a Man had his picture taken he knew Positively that the

The first month the Photographer cleared one million dollars, the second month two million, and so on ad valorem until the proprietor's daughter began to think of marrying a title.

### MORAL :

Photographers, Dressmakers, Printers, and Laundrymen, Take Heed.

## THE EXPORT PHOTOGRAPHIC TRADE WITH SOUTH AFRICA.

British and South African Export Gazette," in its current (last) issue, remarks upon the rapid growth of photographic in South Africa. It cites, as an indication of the recent expansion of this branch of business, the returns for last year, which show the value of imported photographic material at £37,225. Our temporary proceeds:—

Seen, in nearly all countries where clear atmosphere and strong are special features—say, that broad belt of the world contained between 45 deg. of north and south latitudes—importers will fail to find a large call for photographic materials. In most of the countries, South Africa being a notable instance, the demand is high-class, or at least medium, goods, the rubbish which some managers to find a sale in England and in some parts of the continent being held in little favour in Colonial, Indian, and South African markets. It is satisfactory to know that only a very small portion of the cheap and nasty goods is of British origin, and that the United Kingdom, therefore, enjoys a high reputation for quality photographic lines. For example, as much as 70 per cent. of South African importations of photographic material are manufactured in the United Kingdom. The only other countries which have any share in the trade worth mentioning are the United States and Germany, the former with 21 and the latter with 8 per cent. Equally noteworthy is the position held by British goods in the Indian and Chinese markets, but in Central and South America the importations are largely from the United States, while Germany monopolises the market for these lines in the Far East.

### ON MERCHANTING NOVELTIES.

In nearly all countries there is an active demand for novelties, and these are forthcoming in such numbers that importers and dealers

often find they are expected to supply new ideas in photographic goods in greater variety than it would be profitable to stock. Such demands upon the importer are unreasonable, and it has been suggested that a way to meet a somewhat sore point with manufacturers would be for the latter to send out consignments of new goods which they have confidence would readily sell on the principle of sale or return. Once a photographic line gains a vogue in a market, especially among amateurs, its popularity is assured; but it is just as true that really excellent novelties might make no impression in a particular district. If some such system as that suggested were adopted, it might be accompanied by monthly or quarterly payments, with statements showing quantity sold, until the particular line gained an established position. In South Africa alone there are considerably more than 100 firms who now make a specialty of importing photographic materials.

### REQUIREMENTS OF PROFESSIONAL PHOTOGRAPHY.

With regard to the requirements of professional photographers, of whom there are some 250 in South Africa, and it is to be presumed, although exact figures are not available, proportionally as many in others of our Colonies, a regular demand exists for high-class goods of all sorts, increasing every year. Photo-block making processes are not practised to any considerable extent outside Europe and the United States, but there is nevertheless a tendency in this direction in such countries as Japan, Australia, and South Africa, in all of which the larger publishing establishments have now their own plants for undertaking work of this kind; and in many instances photographic reproductions of pictures are made at least equal to those produced at home. There can be no doubt that considerable developments will take place along this channel in the immediate future, necessitating valuable business in the supply of plant and materials. Altogether, the prospects of the trade in photographic sundries are

exceedingly rosy, and there seems to be no reason why goods of British origin should not be even more to the fore than hitherto. The only desiderata for successful business are careful study and constant attention to the prevailing vogues of the markets, and recognition of the fact that in nearly all inferior goods have hardly any chance, and that in many the best only are tolerated.

## Photo-Mechanical Notes.

### Multi-Colour Prints from a Single Plate.

A METHOD of colour-printing in which a single plate of special structure is used in connection with a series of "make-readies" has been patented by G. R. Hildyard, of Dresden House, Nether Street, Finchley, London, N.W. According to the complete specification (No. 16,236, 1907), the process consists first in subjecting zinc or other suitable metal to a treatment whereby a peculiar structure is imparted to the surface corresponding to the different shadows or tones, this structure being of such a character that whilst these parts are rendered very responsive and adaptable in the printing process the liability of the surface to become clogged is prevented or greatly reduced, so that the plate can be run for a considerable time with little or no requirement for cleaning and without detriment to the quality of the work. Moreover, the method by which the different shadows or tones are produced is extremely simple and straightforward as compared with the ordinary methods of manufacture.

In order to produce the peculiar structure above mentioned, a semi-resist film is applied to the plate at the drawing in or production of each tone on the plate, and the plate thus prepared etched with acid, washing off after each etching. The various tones being drawn in or applied with a full resist at each stage of the preparation, prevent the acid from etching the parts to which they are applied for this particular stage, whereas the semi-resist allows the acid to attack the plate in such a way that the other parts of the surface are broken up into the peculiar structure before referred to. The procedure is repeated for each tone or shade, so that in practice the portions of the plate corresponding to the successive tones will be broken up a number of times corresponding to the number of times that particular portion has been placed under the semi-resist. It will be understood that the full resists with which the outline and succeeding tones are drawn in remain on the plate and are unaffected by the etching through the semi-resists.

To make the plate the procedure may be as follows:—

After first preparing the zinc, or other plate, in the usual way (in an alum bath for example), the outline is traced on or applied in the ordinary way. Then all "solids," outline or otherwise, are drawn on with any suitable absolute resist ink. At this stage it is much preferable to put the plate into an acid bath for a sufficient time to bite down practically its whole surface very slightly, so as to slightly raise the "solids" above the general surface. The plate is then washed and thinly coated or rolled up with a suitable semi-resist film; this may consist of a varnish, such, for example, as that which is known as litho middle varnish, with which a little Chinese blue may be mixed. The plate is now placed in a bath of dilute nitric acid, say of about 20 per cent. strength, and is kept still, the surface being watched through a magnifying glass. As soon as a spongy or honey-comb-like pattern appears, the plate is taken out and the acid removed from the surface as quickly as possible. In some cases it is preferable to dip the plate again in the acid for a short time. The plate is now washed off and dried. Next the nearest "solid" parts are painted in with absolute resist, and the plate is again coated all over with semi-resist, and subjected to the acid bath; then it is washed off as before. This procedure is repeated for each tone or shade until the lightest tones have been produced.

When examined through a microscope, the printing surface of a plate thus made appears to be made up of a succession of rounded or undulating elevations and depressions quite different from the sharp, pitted appearance of ordinary plates.

The broken up printing surfaces of plates made as above described appear to possess an absorbent property with regard to printing ink, and if they are rolled up with ink, although the ink is applied to the whole surface, yet the broken up portions retain the ink to such an

extent that they will not transfer it to paper simply placed in contact with them. It is believed that it is this structure which imparts to the plate its peculiar properties of responsiveness and adaptability as regards depth of tone printing under varying pressure, and a small liability to clog in printing.

As a modification of the method of producing the plate, photography may be employed. For example, an ordinary fish-glue or gelatin film may be formed on the plate and exposed under a negative for a short time, just sufficient to insolubilise the outline and solids. The soluble gelatine is then dissolved and washed off. The plate, being preferably bitten down slightly to raise the outline and depressions above the remaining surface, is coated with a semi-resist as before explained and subjected to an acid bath to break up the remainder of its surface as before mentioned. The semi-resist being removed, the plate is covered with another film and the negative is again exposed in careful register and exposed for a rather longer time to insolubilise the soluble parts of the gelatine being again dissolved off. Then a further semi-resist is applied, and the plate is again subjected to the acid bath, and so on until the lightest tone has been produced.

In accordance with the invention, a special and separate make-ready is used for each colour. These make-readies are attached to the cylinder or other impression surface in a yielding or resilient manner.

The drawing shows the impression cylinder in section. The first attached to the impression cylinder *a* in the ordinary manner is a blanket *b* of stout paper or other suitable material, and to the blanket one end of a sheet of the flexible cardboard *c*. To the other end of this sheet is glued a strip of stiff linen or buckram *d* to which are attached a series of elastic hoops *e*. The loops *e* are attached

hooks on the cylinder axle or other suitable part, so that the sheet *c* is resiliently applied upon the cylinder. The sheet *c* is then rolled up to form a make-ready by gluing a suitable number of other sheets of cardboard *c* <sup>11</sup> thereon.

The plate being placed in the machine, it is best to first to pull on a separate sheet of paper to see that the plate is in the proper position.

The plate is now rolled up with the first colour, say yellow. An impression is taken on the make-ready. The plate, of course, prints a yellow picture. Where the given colour, say yellow, is to appear, the operator cuts out card from the make-ready cylinder. The impression surface being thus lowered at these points there will not be sufficient pressure to cause the ink to be transferred and the plate will no longer print there. Similarly, in places where the colour is required to be softer or lighter in tone, all that is necessary is to rub down, or slightly depress the make-ready at these points and as this can be done by hand direct on to the actual impression on the make-ready, it will be seen that the procedure is extremely simple, accurate, and practical. To get heavier tones, on the other hand, the plate may be painted at the required parts with a suitable varnish or the like—for example, gold size, preferably containing a little colouring matter.

The impressions in the first colour having been taken, the make-ready is removed from the cylinder and another plain make-ready substituted. An impression of the plate is taken on this, and any superfluous parts may be removed or rubbed down, or the plate painted with varnish to locally deepen the tone of the colour according to requirement as before, and so on with the colours in succession, a fresh make-ready being prepared and used for each colour. Light and dark colours of a similar nature are to be printed

ple, pink and red—one make-ready can be used for them, the colour being first printed, and then those parts which do not under the dark colour next to be printed are cut out of the make-ready, so that they do not print in the succeeding impression.

In preparing each make-ready, it is preferred to take a pull or impression of the whole plate on a sheet of paper, right over an impression of the colour or colours so far completed. The operator has only to compare this with the original, to see at once which of the successive make-readies should be removed, modified, or red.

Binary litho or printing ink or any other suitable ink may be employed. As is known, printers generally dilute the ink with turpentine. For the purpose of the invention it is preferred not to do but to dilute the ink with a suitable oil. For example, a mixture of 1 part of good lubricating oil, such as sperm oil, to about 5 parts of turpentine, 6 parts methylated spirits, and 1 part strong ammonia of, say, .880 sp. gr. It is of advantage even to wash the plate with this mixture before painting on the size, so as to ensure a fine surface.

When gold size is used for painting portions of the printing surface to get heavier tones as above mentioned, and remains on the surface for some days, as frequently happens in long runs, it is somewhat difficult to remove the size from the plate by ordinary means. It can be readily removed by rubbing the plate with a mixture of 2 parts of turpentine, 6 parts methylated spirits, and 1 part strong ammonia of, say, .880 sp. gr. It is of advantage even to wash the plate with this mixture before painting on the size, so as to ensure a fine surface.

It will be seen that the method of printing above described is the opposite of that usually employed in colour printing. In these make-readies are progressively built up to produce the deeper tones, whereas in the present process the make-readies are, so to "built down" to produce the lighter tones.

#### PHOTO-MECHANICAL PATENTS.

The following patent has been applied for:—

**TYPE-SETTING.**—No. 15,626. Improved process for making Autotypes and apparatus therefor. Eugen Albert, 28, New Bridge Street, London.

## Patent News.

*Process patents—applications and specifications—are treated in the Mechanical Notes.*

The following applications for patents were made between July 27 and August 1:—

**COLOUR PHOTOGRAPHY.**—No. 15,937. Apparatus for copying colour plates. John Henry Smith and Waldemar Merckens, 40, Chancery Lane, London.

**REFLEX CAMERAS.**—No. 15,951. Improvements in foldable reflex cameras. Optische Anstalt C. P. Goerz Akt.-Ges., 31, Bedford Street, Strand, London.

**LIGHT FILTERS.**—No. 15,963. Improvements in or relating to light filters. Friedrich Albin Schanz and Karl Stockhausen, 111, Hatton Garden, London.

**SCREEN-PLATE COLOURS.**—No. 15,983. Improvements in screen-plate colours for colour photography. Harold Frederick Smith, 33, Chancery Street, Peterborough.

**PRODUCING MEANS.**—No. 16,084. Improved means for producing distance copies of drawings, photographs, writings, and the like. John Jarl Waddington, 47, Lincoln's Inn Fields, London.

**RELATING TO FILMS.**—No. 16,114. Improvements in or relating to the manufacture of film for cinematograph and like apparatus. Société Anonyme des Plaques et Papiers Photographiques, A. Lumière et ses Fils, 111, Hatton Garden, London.

**RELATING TO FILMS.**—No. 16,115. Method of renovating or re-etching worn cinematographic films. Société Anonyme des Plaques et Papiers Photographiques, A. Lumière et ses Fils, 111, Hatton Garden, London.

**DEVELOPING MEANS.**—No. 16,203. Improvements in means for developing photographic plates. Ralph Emerson de Lury, 33, Cannon Street, London.

**PACKING MEANS.**—No. 16,206. Improvements relating to the packing and

development of flat photographic films. James Worms, Birkbeck Bank Chambers, Southampton Buildings, London.

**COPYING.**—No. 16,272. Improvements in apparatus for reproducing at a distance pictures or designs. Edouard Belin, 5, Lord Street, Liverpool.

**PRINTING.**—No. 16,277. Improvements in or relating to the photographic reproduction of images. Frank Wordsworth Donisthorpe, 7, Southampton Buildings, London.

**PRINTING.**—No. 16,294. Improvements in or relating to the photographic reproduction of images. Edmund Seal Donisthorpe, 7, Southampton Buildings, London.

#### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**LIGHT-FILTERS FOR SCREEN-PLATE EXPOSURES.**—No. 23,738, 1907.

The present invention relates to the yellow filter which is applied near the lens when making exposures upon a photographic sensitive surface, between which surface and its support a polychrome intermediate layer is situated, as, for example, in the Lumière Autochrome plate. The filter usually consists of a plate or disc, the front and rear surfaces of which are plane and parallel to one another.

According to the invention these filters are only modified with a view to rendering them available for a second purpose. As already known, in exposures upon the sensitive surfaces above mentioned, light has to penetrate the polychrome intermediate layer before it reaches the photographic sensitive surface. The support of the sensitive surface is therefore given a position in the camera the reverse of that obtaining in ordinary photography, so that the surface lies at the back of the support, that is to say, on the side remote from the lens. In exposures either a filter of any thickness is to be placed in front of the lens and the distance between the latter and the support (obtaining in the case of ordinary exposures) reduced by a certain amount which is somewhat smaller than the thickness of the support; or a filter having about double the thickness of the support is to be set behind the lens. In the latter case, the reduction in distance between the lens and the support is dispensed with, as the effect of the thick filter is to restore the coincidence of the image plane and the sensitive surface.

When the first of these two methods is followed, in focussing by shifting the lens according to the ordinary scale of distance a final shifting has afterwards to be made. In focussing by means of a ground glass screen it is necessary that this screen has the same thickness as the support of the sensitive surface and is placed the reverse way in the camera, so that the ground side is remote from the lens. When the second method is followed, the lens has only to be shifted according to the ordinary scale or the screen used in the ordinary way. In spite of its apparent simplicity, the second method—setting the yellow filter behind the lens—is seldom made use of, because the insertion of the filter into the interior of the camera is particularly troublesome and causes a loss of time.

By the present invention the filter placed in front of the lens is invested with the advantage hitherto only possessed by the filter set behind the lens, viz., that the ordinary methods of focussing remain in use. According to the invention a yellow filter is made use of which has not as hitherto the effect of a homogeneous plano-parallel plate, but that of a weak dispersive lens, by virtue of one or several (external or internal) surfaces being spherical. In consequence of this filter-lens acting in co-operation with the objective, the focal length of the latter is, as it were, increased a little, which increase corresponds to the backward displacement of the sensitive surface.

The increase in the focal length of the objective incidental to the filter-lens should amount to about two-thirds of the thickness of the support, that is 1 mm., when this thickness is 1.5 mm. If the focal length of the lens proper be 150 mm. a negative focal length of the filter lens of 22.5 metres would just bring about this increase. The same filter lens would also suffice for objectives of 145 mm. and of 155 mm. focal length, without the position of the image being so much displaced relatively to the sensitive surface as the casual differences in the thickness of the supports would amount to. In

general, the greater the focal length of the objective the greater must the focal length of the filter lens be chosen.

The displacement of the image due to the influence of the filter lens is not independent of the distance of the object to be taken, but the variations in displacement for the ordinary distances at which photographs are usually taken, and which represent a high multiple of the focal length of the objective, are again smaller than the chance differences in the thickness of the supports. Ernst Wandersleb, Carl-Zeiss Strasse, Jena, Germany.

**FILM-HOLDERS.**—No. 23,973, 1907. The invention provides a rectangular frame of metal or other suitable material whose horizontal top and bottom members are curved in plan, while its vertical members are formed with grooves for the reception of a film. The flat photographic cut film to be developed is placed in the frame by being directed vertically downwards in the grooves of the vertical members and on to a ledge provided on the bottom member, the film thereby being caused to conform with the curvature of the frame, which curvature has the effect of preventing any buckling or curling of the film during the processes of development.

A number of these curved film holders may be used in conjunction with a known bath consisting of an outer casing provided with a removable internal frame formed with vertical grooves for the reception of the film-holders, when a large number of films can be treated simultaneously, thereby effecting considerable economy of time and expense. Benjamin Thomas Akers, 1, Wells Road, and John Edward Wilson, "Dunholm," King's Road, both of Ilkley, Yorkshire.

**STEREOSCOPIC PRINTS.**—No. 9,260, 1907. The invention relates to a method of taking stereoscopic negatives on separate plates or films

Fig. 1.

in such a way that the negatives can be immediately printed from on single pieces of sensitive paper. No portion of the picture is

photographed which is not necessary for the true stereoscopic effect. The invention also allows for the different angles of view according to the distance of the object photographed; in other words, nearer the object then the wider are the plates separated from one another, while, on the other hand, the more distant the object nearer the plates, thus giving a converging movement similar effect to the converging movements of the human eyes. The apparatus does not interfere with the interdistance of the lenses, this interdistance controlling the relief effect. Any distance between the lenses may be used, the plates being afterwards adjusted to the reflection on the focussing screens from the lenses.

A camera is used provided with a dark slide capable of containing in two separate chambers (one holding each strip) two strips of plate or sensitive film side by side in a perpendicular position. This slide is adapted to move downwards and repeat so as

Fig. 2.

allow stereoscopic pairs of photographs to be taken to the full length of the strip. The strips of plate or sensitive film are widened apart from each other until exactly the same field of view is obtained on both plates. In this manner the centre of the object photographed is exactly reflected in the centre of the plate. By this means the trimming previous to mounting has hitherto been necessary for stereoscopic prints is unnecessary.

The arrangement of strips of plate or film has the further advantage that it does away with the inconvenient method hitherto usual of printing one negative and then by a movement printing another, or printing one pair of negatives (a stereoscopic slide) then printing other subjects. The plates or films of this invention may be developed and printed, thus affording a means of producing stereoscopic photographs in quantities without separating pictures.

Figure 1 shows the back view of the dark slide with back removed so as to show the position of plates and the means of separating the strips of plate or film. A, A are the strips of plate held in the carriers BB. CC are the focussing screens, which move in grooves and are adjusted by the pinion D and rack

h simultaneously adjusts the plates A A by racks E2 E2 until image coincides, which image is brought into register by having or more lines perpendicularly drawn across the ground glass the same position on each. Then when any elected parts are ed by these lines the images must correctly register and cover same field of view. F F are the rebates at side of camera in h the slide repeats downwards any number of exposures, and e lenses retain the same position any optical centres or distance een may be used.

ure 2 shows the movement of the plates as applied to the al system. G G are the lenses projecting the object H photo- ed at H2 and H2. The plate carriers B B and the back F ional sectionally viewed shows how the plates are widened

Fig. 3.

they are covered by a coincident picture in perfect register to edges.

ure 3 shows the printing frame with back removed; A A being negatives reversed as to their relative position. I I are border ives with opaque centres and stereoscopic borders, such as a, garden windows, or any other thing that may leave a clear r edge in centre. This centre being opaque, the border prints copic effects on the sheets of paper as it passes after having rted on from the negatives A A, which are masked to a white margin. The resulting print gives effects such as a n a frame, the whole being stereoscopic with no blurred or pping edges where the printings meet. The oblong shape of gatives A A keeps the picture truly parallel as necessary for copy. Gilbert Dyas, 9, Mary Street, Dublin.

FROM BOOKS.—No. 6,275, 1908. Protection is claimed for a s described as follows:—Sensitised paper (bromide paper) is e face downwards on the page to be copied; a back or under- of some stiff material, such as cardboard, thin sheet metal, s is arranged under the page, and the sensitised paper and e together pressed against this back with the help of a cover of glass or other suitable transparent material. In the f paper or pages written or printed on one side only, the of the back or under-layer is not of importance, but with containing also printed or written matter on the rear side, been found advisable to use only black or non-actinic colours r, red, green, or black (and the like) for the back or under r a glass plate covered with tinfoil or a colour filter may be

pressing the glass cover-plate tightly against the under-layer qualities can be removed, so that the intimate contact of the ed surface with the paper or page to be copied, which is rry to secure a sharp copy, is ensured; this is of especial nce in the case of old and creased books.

also essential, more particularly for copying from old and ooks, that the book cover lying under the sheet to be copied e placed somewhat higher in the middle on a supporting e like, in order to better place the transparent pressing hich easily becomes curved when the book is fastened up. y also be mentioned that in the photographic printing pro- ore particularly in making copies of old prints, etc., in which ed paper is placed beneath the print to be copied and the ed through the print on to the paper, better results are d if the under layer is of non-actinic colouring (yellow, red, or black).

The invention includes a printing or copying device consisting of a plate or support for the book, which plate may be arranged on legs, and against which plate the book with the sensitised paper is pressed with the help of the glass cover-plate in conjunction with suitably arranged screw-clamps, levers, etc. Carl von Arnhard, 16 Wilhelmstrasse, Munich.

The following complete specifications, etc., are open to public inspection before acceptance under the Patents Act, 1901:—

DEVELOPMENT.—No. 15,657. Photographic developing and fixing solutions. Jeannot and Bremner.

COLOUR PHOTOGRAPHY.—No. 15,937. Apparatus for copying colour screen-plates. Smith and Merckens.

## New Trade Dames.

BROMOIL.—No. 303,988. Photographic papers. John J. Griffin and Sons, Ltd., Kemble Street, Kingsway, London, W.C., photographic paper and apparatus manufacturers. June 17, 1908.

"CARLEENCO."—No. 304,209. Photographic mounts, Christmas cards, albums, almanacs, and other similar articles of paper or cardboard, all being goods included in class 39. Carl Ernst and Co., 27 to 31, Earl Street, Finsbury, London, E.C., mount manufacturers. June 25, 1908.

## FORTHCOMING EXHIBITIONS.

September 11 to October 24.—Photographic Salon. Entries close August 31. Sec., Reginald Craigie, 5A, Pall Mall East, London, S.W.

September 17 to October 24.—Royal Photographic Society. Entries close September 1. Sec., J. McIntosh, 66, Russell Square, London, W.C.

December, 1908, to January, 1909.—Kiew International Photographic. Sec., S. T. Horovitz, Technical Society, Kreshtchatik, 10, Kiew, Russia.

1909.

January 6 to 27.—Northern Photographic (Manchester). Entries close December 11, 1908. Sec., S. L. Coulthurst, Broad Oak Road, Worsley, Manchester.

## Analecta.

### The Finish of a Hundred Yards' Race.

I do not think that there can be any doubt (writes Mr. Adolphe Abrahams in "Photography and Focus" for August 11) that the ideal position from which to take the finish of a race is as nearly straight as is practicable. One naturally desires to secure the figurez as large as possible, and therefore one stands as near to the tape as width of plate and number of runners allow. I would here point out that if the photographer is not sufficiently generous regarding margins, it is always a runner on one of the extreme sides who re-pays him by coming in first and spoiling the photograph. The problem, therefore, is how to stand in the middle of the track, pretty close to the runners, and yet without a mishap. The consequences of an eleven-stone man with a velocity of ten yards a second crashing into the camera and its operator are not pleasant. Yet the correct position is easy to adopt.

The strings which separate the sprinters are attached to upright poles close to the finish. Starting at one of the two centre uprights, one should walk straight back to the distance selected. When the men finish, they will run easily right and left past him. I have often seen a big field camera erected in such a position without anything untoward occurring.

If it is compulsory to take a picture from one side, it is well to try to find out on which side is the likely winner, and then to select the side opposite to him.

Exposure is made, of course, as the winner breaks the tape. The

duration of the exposure will depend on the proximity of the camera to the finish. If one is as near as the width of field will permit, 1-400 sec. will give a sharp image with a little blurring of the feet; probably 1-800 sec. will give perfect sharpness.

### Photographic Dish Stains.

One kind of stain (says a writer in "The Amateur Photographer and Photographic News" of August 11) comes in a most aggravating way, and that is in developing gaslight papers, with a metol-hydroquinone developer. A certain amount of reduced silver, of the black form, of course, is thrown down, and this adheres to the dishes with extraordinary tenacity. Metallic silver is easily dissolved by concentrated nitric acid, and it is this re-agent which must be used in order to cleanse the dishes. The commercial form of nitric acid is quite good enough, and should be used with caution, a little being poured into the dirty dishes, and the latter rinsed out with it. The acid at once removes the stain, and the dish should then be filled with water in order to dilute the acid before it is poured into the sink. Sapollo or some similar soap will enable one to get off these silver stains, but the acid is far preferable. Most developers containing alkaline carbonates, and more especially M.Q., deposit a rough substance on the sides and bottom of a dish which water will not touch. This stuff, however, is immediately soluble in weak acid, and dilute hydrochloric or nitric acid may be used. It is only by keeping one's dishes scrupulously clean that the minimum of trouble can be assured, and developing dishes more especially should receive constant attention.

## New Books.

"Anleitung zur Photographie." By G. Pizzighelli. Thirteenth edition. Halle: W. Knapp. M. 4-50.

The fact that twelve previous editions of this general text-book of photography have been exhausted should render unnecessary any other recommendation of ours. The arrangement and production of the volume are excellent in every way, and the supplemental half-tone plates which are collected at the end should be an encouragement to the reader in his aim at striking, if not invariably pleasing, results. The handbook is written solely for the person who desires practical success; the theoretical considerations which figure so largely in many German works do not for man appreciable portion of it. If, as we may suppose, the technical advice represents the present practice in Germany, we may express surprise at one or two of the procedures advised. Thus among processes of sulphide toning of bromides the only bleaching formula is a mixture of potassium bichromate and hydrochloric acid, a bad prescription for a workable sepia-toning process. Ozobrome and carbograph are included among pigment processes, but the year-old oil process does not appear to have yet impressed the Teutonic worker, who, we believe, continues to find in "gum" all the opportunity for riotous control which he desires.

A GERMAN HANDBOOK OF RETOUCHING. — A third edition of the "Anleitung zur Positiv und Negativ-Retouche," by Carl v. Zamboni, has been issued by Herr Knapp, Halle, at M. 2-40. It deals with the retouching of both portrait and landscape negatives, although the former naturally receives the lion's share of the writer's treatment. The working up of prints and enlargements in black and white, with chalks and in colours, is also the subject of two chapters. The volume, which throughout seeks to give the reader practical instruction, contains a series of useful plates showing examples of retouching.

EDER'S "REZEpte AND TABELLEN." — The seventh edition of the photographic tables and formulae, collected and edited by Dr. J. M. Eder, reaches us from the publisher, Herr W. Knapp, of Halle a/S, by whom it is issued as a cloth-bound volume at M. 3. The formulae have evidently been brought up to date since the last edition, as witness the inclusion of the Autochrome prescriptions and directions for sepia sulphide toning as worked out in this country, and doubtless practised with equal success in Germany, though to a less extent, we believe, than here. The footnotes to many of the formulae giving references to more lengthy information on a particular subject are a

commendable feature of the compilation. The contents, it should be added, embrace both photo-mechanical and photographic processes and are systematically arranged under appropriate headings.

ERRATUM.—In the review of "The Study of Stellar Evolution" our issue of July 31, the price was wrongly given as 10s. 6d. net. It is 16s. 6d. net.

## Dew Apparatus, &c.

The "Tella" Reflex Camera. Sold by the Tella Camera Co., High Holborn, London, W.C.

The reflex camera, introduced under the name of "Tella," recently been submitted to us for examination by the company, is certainly an instrument of particularly notable qualities. Advantages of the reflex principle are sufficiently widely recognized by all classes of photographers to make it superfluous to dwell upon them, nevertheless, the great convenience and certainty of focussing have the drawback that bulk and weight are ali-

Fig. 1.

inevitably the accompaniments of a reflex camera. The "Tella" been specially designed to reduce both size and weight, and success, which has attended these efforts should be sufficiently obvious when we say that the instrument before us, which takes picture of quarter-plate size, measures 5 x 6 x 5 inches, although is an apparatus of the double-extension type, giving an extension all of twelve inches. As regards weight, the camera, together with the lens, weighs 2½ lbs., and when carried in the hand makes weight felt less than a good many cameras even of the ordi-

Fig. 2.

pattern. The worker, therefore, who may have been deterred from availing himself of the reflex advantages would be well advised to inspect the "Tella" camera before taking it for granted that its objections of size and weight are insuperable in his case.

As regards the movements of the camera itself, we would first point out that it possesses the great advantage of a rise of front of 1 equal to one-third the vertical height of the quarter-plate. Extension is obtained, first of all, by direct racking out of the bellows, which gives a distance from lens to plate of 10½ inches; the additional inch and a half is then obtained simply by removing

sliding the lens panel, which carries a collar just over one inch. On the panel being reversed this collar projects, and the lens is then screwed into the front of it the total long extension is increased, as shown in the third illustration.

The lens panel is leather-covered on both sides, so that at full extension, it will all be in the normal position, the finished appearance of the camera being preserved. The focussing rack and pinion are placed on the right side of the instrument and the shutter release on the left, the latter being only adjustment on that side of the camera, a plan which prevents any accidental mistake, even by the beginner. The adjustments of mirror and shutter are very nicely contrived. The mirror works wonderfully lightly, and, as we have found in our own experience, with freedom from vibration. The shutter is kept at constant tension, and the speeds obtained by altering the width of the aperture which is done by winding the shutter until the bottom aperture is level with the lower side of the reversing back; the shutter winding-key, B in the drawing, is then pressed in and the shutter is wound until the desired shutter speed is obtained as shown in an indicator, G, on the other side of the camera. The shutter also provides for time exposures. The reversing back is made of detachable pattern, and has one good feature which should not be overlooked, namely, that in the position for vertical pictures the

Fig. 3.

slide is inserted from the bottom of the camera so that the back of the pull-out dark-slide is shielded by the camera itself from direct sunlight, the slide being, in fact, upside down while in readiness for exposure in the camera. This is but one point which shows the care taken in the designing of the instrument, and the camera altogether impresses us as a suitable instrument for the tourist, or indeed general, work. Its price is ten shillings with six single dark-slides in quarter-plate size, or £14 15s. Ross "Homocentric," Series III., f/6.3. A tropical model of the camera built of polished teak and brass-bound and screwed at every joint, is made for climates where extremes of heat and damp may be reckoned for. This camera only with six slides, is sold at £15.

Watkins Bee Meter and Compass, made by the Watkins & Co., Imperial Mills, Hereford.

The combination of the popular Bee meter with a compass in such a way as scarcely to increase the size of the instrument, should surely be appreciated by photographers, who can often make good use of the latter accessory. A knowledge of the compass bearings will often enable the photographer to predict with certainty when the sun will be in the position to give the best lighting. A record of the point to which the camera lens points will be of assistance in obtaining a second negative of clouds for printing purposes, and in record work of any kind compass bearings are necessary to make the record complete. In addition to all this, the use of a compass in finding one's way about a strange country is obvious. The price of the "Bee Compass-Meter" is 3s. 6d.

## CATALOGUES AND TRADE NOTICES.

**THE FOLDING RUBY CAMERA.**—Two supplementary lists or pamphlets issued by the Thornton Pickard Manufacturing Company give particulars of this well-designed hand-stand camera and of the Beck "Isostigmat," Ross "Homocentric," and Ross-Zeiss lenses, which can be fitted to it. The lists convey some useful lessons in the way of the value of range of focal length and great covering power.

**"A BETTER ARGUMENT."**—Messrs. Raines and Co., of Ealing, compel our admiration by the thoroughness with which they do all their work, not excepting that part of it which informs the professional photographer of the many-sided "Raines Service." Their latest publication in this direction is entitled "A Better Argument," and logically points out the power of the double business lever (quality and promptness) which Messrs. Raines operate from their well-appointed works at Ealing. A piece of reading which is quite worth applying for.

**KENNGOTT SHUTTERS, TRIPODS, ETC.**—A new list, issued by W. Kenngott, 64, Rue de Saintonge, Paris, and 45, City Road, London, E.C., describes in French, German, and English the many special manufactures and other high-class goods handled by this firm. Specially worthy of mention is the great variety of folding metal tripods and similarly popular photographic accessories. The various patterns of the Kenngott "Koilos" shutter are also a feature of the list, which also lists and describes full series of folding, reflex, and other cameras, lenses, finders, etc. Those interested should apply for a copy.

## Commercial & Legal Intelligence.

**NEGATIVES OF TAPESTRY.**—At the Buckingham County Court last week, Percy Edgar Smith, trading as Varney and Co., photographers, Bridge Street, Buckingham, sued Lewis Edwards, of The Dingle, Cookham, fine art dealer, for £8 8s. for work done in photographing tapestries in Stowe House, and supplying prints of the same.

Mr. Law, for the plaintiff, stated that on the 7th of March last the defendant, who lived at The Dingle, Cookham, Berks, and was a fine art dealer, called on the plaintiff at his studio in Buckingham and requested him to take some photographs of five pieces of tapestry in Stowe House. The plaintiff told him that he must have authority to take the photographs before he could execute the work, and permission would have to be obtained of Mr. Morgan, agent to the Baroness Kinloss. Defendant said he would see Mr. Morgan and obtain the permission required. Defendant said he wanted good photographs because he was going to send them to experts in order to ascertain whether the tapestries were genuine. The plaintiff went over to Stowe House and photographed the five pieces of tapestry separately, and sent three prints of each to the defendant and one print of each and the negatives to Mr. Morgan. The five prints sent to Mr. Morgan, he presumed, were as an acknowledgment for the permission given to take the photographs. There evidently had been some conversation between Mr. Morgan and the defendant respecting the negatives, and the defendant told the plaintiff that the negatives must be destroyed. And now he had to add that after the tapestries had been photographed and the work further attaching to the execution of the order was in progress, Mr. Morgan called at the

studio of the plaintiff and said that the negatives must be sent to him at Stowe, and that the defendant would pay the plaintiff his bill. It was on that statement that the negatives were sent to Mr. Morgan, together with one print each of them.

The bill was sent into the defendant. No price had been mentioned, and the plaintiff charged the reasonable sum of 8 guineas. He had no reply, and after waiting about a fortnight he sent in another bill to account rendered, and a letter was enclosed stating that as the defendant had no ledger account with the firm he was asked to give references. After waiting a reasonable time and no reply being received the plaintiff wrote another letter stating that unless there was a settlement of the account within seven days he should place the matter in the County Court. No reply was received, and the plaint was placed in the County Court, and not until that course had been taken did the defendant move at all in the matter.

Leonard Varney said: I live in Buckingham and am a retired photographer, and for forty-one years carried on the business in Buckingham. I know what work was involved in photographing the tapestries at Stowe House, and I consider the charge of 8 guineas very reasonable. I should have charged 2 guineas each plate, or if I was allowed to have retained the negatives the charge would have been one guinea each. Where I gave up the negatives I always charged a double fee. In this case twenty prints were supplied. I should charge 3s. for unmounted and 3s. 6d. if mounted for the size prints supplied by the plaintiff. That would be £12 15s. altogether. That would be very reasonable indeed.

Guy Hughes said: I am a photographer carrying on business in Baker Street, London. I have had experience in all kinds of photography. I have seen the statement of claim, and considering the work and labour involved I consider the 8 guineas charged to be very reasonable indeed. It is very much lower than I should have charged for the work, especially as the negatives were handed over. I have had as much as 5 guineas for a negative.

By the Judge: They are excellently taken. It is far more difficult to photograph tapestries, which are fixtures, than oil paintings, because the latter can be placed on an easel and moved about in order to procure the proper light. The negative of these tapestries would be a valuable asset in the business.

Lewis Edwards said: I live at The Dingle, Cookham, and my occupation is that of a fine art dealer at the present time, and prior to that my occupation was that of a practical photographer. In pursuance of certain communications I went to Stowe House and saw Mr. Morgan. I saw the tapestries and I expressed the belief that I could procure a customer for them, but before I could do this I said I must have photographs of them. Mr. Morgan said he believed that Varney and Co., of Buckingham, possessed negatives of the tapestries. I saw plaintiff, and he said he had no negatives, and that if I wanted the tapestries photographed I must gain permission of Mr. Morgan. I told him that 8½ in. by 6½ in. would be sufficient for my purpose, but he suggested that they should be the larger size, and I agreed to it, but I told him that he was not to make them too expensive. . . . The next I heard about it was when I received the fifteen prints, that was three each of the five pieces of tapestry. I did not receive the negatives. They were to be sent to me with the prints, and one print each of the five pieces of tapestry were to be sent to Mr. Morgan. The reason why I stipulated that the negatives were to be sent to me was that no more prints should be issued, so that no copies of the tapestries could be taken. If that was allowed the designs of the tapestries would become common. It was hardly likely I should pay 8 guineas for fifteen prints. The negatives were sent to Mr. Morgan without my knowledge or permission. The price of 8 guineas for fifteen prints is simply absurd. I know what photography is. I told the plaintiff that the negatives would have to be destroyed.

Harry James Wilson, carrying on business in Harrow Road, a photographer of forty years' standing, stated that he considered the charge of 10s. each plate would have been ample payment. That would have been £2 10s. for the whole charge. It was only four miles out of the town. He would like to keep on at that price all day long. He thought an oil painting far more difficult to photograph than a tapestry. He had not had any experience in photographing tapestries. His price of 10s. per tapestry included the negatives.

The jury found a verdict that the plaintiff was entitled to the amount he claimed. They considered that the charge of 8 guineas was a fair price, seeing that the plaintiff had given up the negatives.

The Judge said the verdict was in favour of the plaintiff, with costs.

**A BRISTOL BANKRUPTCY.**—At the Bristol Bankruptcy Court on Friday the public examination of Ralph Winter Thomas, carrying on business at 69, Stokes Croft, Bristol, as a photographic dealer, was declared closed.

**LIMITED PARTNERSHIP.**—Parrish and Berry, photographers and dealers in photographic requisites, 3, Waltham Street, Hull, have registered a partnership for seven years from April 1, 1908. General partner:—Mr. R. W. Berry, 3, Waltham Street, Hull. Limited partners:—Mrs. E. C. Berry, 100, Alliance Avenue, Hull, contributing £500 cash, and Mrs. E. Parrish, 547, Anlaby Road, Hull, contributing £425 cash.

**LIABILITY FOR CANVASSER.**—At the Greenwich County Court last week Arthur Denny, a clerk, of Burwash Road, Plumstead, sued the Greenwich Fine Art Academy, of 97, Woolwich Road, for £1 ls., paid for an enlargement of a photograph which had not been delivered. Defendant admitted receiving the small photograph for enlargement, but denied receiving the guinea sued for. Plaintiff said that the person who received the photograph was allowed that sum. The judge held that the defendants were bound by the acts of their agents, and found for the plaintiff with costs.

## News and Notes.

**DEATH OF MR. F. H. WENHAM.**—At the moment of going to press, we very much regret to hear of the sudden death, at the great age of eighty-four, of Mr. F. H. Wenham, one of the first photographers of the old days, and perhaps better known to the photographic passing generation than to the present. We must postpone until next week a fitting reference to the optical and other inventions of the deceased gentleman, and to the almost romantic story of his life.

**"URBANORA" AT THE PALACE THEATRE.**—There has just been included in the "Urbanora" exhibit at the Palace Theatre a full series of animated pictures of what cannot be regarded other than as the most memorable Cowes week—alike from a national, a social, and a sailing point of view—that has ever been celebrated on the Solent. The scenes, which were expressly taken for this theatre by the Urban operators and are singularly clear in definition, include views of "Shamrock," "Germania," "Cicely," "Britannia," "Creole," "Carina," and other racers in all classes, as well as the splendid cruiser "Indomitable," and a delightfully intimate picture of their Majesties on board the Royal yacht.

**GLASS BOTTLES.**—The world's largest bottle factory is at Düsseldorf; and in his report on the trade of the district (Westphalia and the Rhenish Provinces), Mr. Consul Koenig (No. 4059, Ann. Series) gives some particulars of the company which is, conjointly with other German and Continental manufacturers, introducing "Owen Patent Glass Bottle Machine." The latter will, says the Consul, revolutionise the manufacture of glass bottles in all the factories, and he expects that the art of blowing glass bottles by hand will have become extinct in about ten years' time. The export trade of the Düsseldorf glass works is very large. The Rhenish Westphalian Coal Syndicate was unable to supply the Düsseldorf glass factory with sufficient coal last year, and the board of directors was forced to import very considerable amounts of coal from the United Kingdom at enhanced prices. There is now a regular trade of coal from the United Kingdom, chiefly from Newcastle, up the Rhine to Düsseldorf.

**DEATH OF M. JOSEPH MAES.**—M. Joseph Maes died at Antwerp on August 4 at an advanced age. He was one of the pioneers of photographic mechanical printing, and probably the first person to do collotype work on a cylindrical machine. He had a large establishment in the Bourse, and only a short time ago produced an excellent illustrated booklet on "Maritime Antwerp." M. Maes retired from active business life some time since. He was the author of the article on "Antwerp as it is," which he wrote expressly for this year's handbook of the Photographic Convention on the occasion of its cent visit to Belgium. He was president of the Antwerp section

"Association Belge de Photographie," and was present not only at the opening of the Brussels meeting, but also at the option given to the members by the Burgomaster at Antwerp on 10th ult. M. Maes was a kindly and courteous gentleman, and death has caused widespread regret among all who had the pleasure of his acquaintance.

**HOLIDAY BOOKLETS.**—The St. Catherine Press, Ltd., 8, York Buildings, Adelphi, London, W.C., have recently issued a series of illustrated booklets dealing with the districts of Frinton-on-Sea, Lytham, Lanark, and Peebles. These little guide books are tastefully got up and of convenient size, being easily carried in one's coat pocket. They supply the visitor with information as to hotel accommodation, etc., facilities for sport, and a brief description of the objects of interest in the towns and surrounding districts. Copies may be obtained free on application to the respective town clerks.

A DENVER READER of the "B. J.," Mr. J. Collier, who for many years past has conducted a business in the Colorado capital, sends us a book of views published by himself from his own negatives. The plates, particularly the interior views—the Courts of Justice, Government House, and other Denver buildings—are fine examples of technical photography, and secure very good reproduction at the hands of the block-maker and printer.

## Correspondence.

*Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*We do not undertake responsibility for the opinions expressed by our correspondents.*

### A FRAUD ON PHOTOGRAPHERS.

To the Editors.

Gentlemen,—The man who called upon your correspondent, "H.," is probably nearly related to a man who called upon me in November, 1905. He brought a card of introduction from a friend of mine (although how he obtained possession of it has always remained a mystery). He said he was a farmer about to leave the country, and then held, and wanted a number of 12 x 10 photographs taken, especially to please his wife, who was much attached to the place. He was a shortish man, about 45, and his general get-up made him very much like what he professed to be. He gave the name of Henry Forrester, and his address as Church Hill Farm, Ivinghoe, Bucks. Tring.

It was arranged that I should go and take the pictures the following day, and he was to meet me with a trap at Tring Station, and come to his place at Ivinghoe. Up to this time there was nothing to arouse suspicion, except perhaps that he had not inquired at the approximate cost would be. Just before he left, however, he mentioned that he had been to the cattle market that morning and run himself quite out of money. When I showed no inclination to rise to the occasion, he casually observed that he had a friend at the Temple who would give him a cheque for any amount, so I suggested that he had better go there and get it. It would not take long, and if he would allow me I should be pleased to lend him the money to get there. He hesitated, then expressed his willingness to show the amount, and I handed him sixpence.

The next day, I found it would be impossible for me to go on the day arranged, so wrote and suggested the following Monday. On Thursday afternoon I received an unsigned postcard (which had been posted in London) saying my visit must be postponed for the present, and on the Friday morning my letter was returned from Ivinghoe marked "Not known."

I shall try and induce the next farmer who calls upon me with a similar yarn to give me a sitting; perhaps then your correspondent may be able to exchange notes.—Yours truly,

F. A. BRIDGE.

1, Dalston Lane, London, N.E., August 8, 1908.

## Answers to Correspondents.

\**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*

\**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

\**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*

\**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

Charles S. Harris, 77, London Road, Dover. *Photograph of the Tableau of the Final Performance, Dover Pageant.*  
John Pryce Blair, 19, Lavant Street, Petersfield, Hants. *Two Photographs of Haslemere Town Band.*

**CHROMIUM INTENSIFIER.**—I find that the chromium intensifier, when applied to some negatives, produces dark stains, which fade away if the negative is immersed for some time, but meantime the deposit may be more than desired. Please explain this.—ENTHU.

From your description of the stains, they are due to applying the process to imperfectly washed plates. If the stains are permanent, imperfect fixing is indicated; if they disappear by long soaking in the bleacher, then washing is imperfect, and traces of hypo remain in the film. When the stains appear strongly it is best to apply a fresh bleacher, as the solution is materially affected and exhausted by hypo.

**FIXING BATH, ETC.**—1. Will you kindly inform me if the hardening fixing bath recommended in "Blisters on Bromide," in your issue of the 31st ult., has any advantage over Prof. Namias' formula with acetate of soda which you gave in an issue some considerable time ago, and whether ordinary alum or chrome alum will do equally well as potash alum, and if not why not? 2. Can you recommend another intensifier than Lumière's pyro-nitrate of silver for Autochromes? That is so messy and stains so, and, moreover, often acts too quickly; I suppose more water with it would remedy this? Generally speaking, I think Autochromes are softer, more pleasing, and colours less crude and garish without intensification; but sometimes it is necessary. 3. I find that I can develop my Autochromes under the dark-room light without fogging—have got some excellent ones so done, but have difficulty in telling when to stop development. Can you tell me how to judge the plate by its appearance to know when to stop? If developed too much, I fancy the reversing bath eats too much away to get good results, and destroys detail (and colour) in high-lights, particularly whites and light blues. A friend tells me that in his experience it is difficult to over-expose the plates too much, and that the great thing is to give a full exposure and not to carry development too far. He, too, takes his plates to the light soon after developer is on, but, of course, does not expose them unduly to it. I use rodinal.—F. C. BRAY.

1. There are many fixing and hardening baths available, and we should not care to say which have special advantages. Chrome alum will probably do just as well as the other. 2. You can use a mercury intensifier, mercury and ferrous oxalate being the best. But we prefer the silver intensifier to any. Your troubles are probably due to allowing it to act too long. It should be thrown away as soon as it begins to appear yellow in colour. Our experience is that the majority of Autochromes require intensification, but that it is easy to overdo it. 3. We have no experience of judging the development by inspection, as we prefer working in the dark by time. We do not agree with your friend that it is difficult to over-expose the plates, as we have lost many from that cause. The best results are, however, to be obtained by full exposure and short development. This is the best way to obtain good whites. Of late

we have produced very satisfactory results by using Watkins' Autochrome meter, taking the speed of the plate as 2 and developing for 2 minutes instead of  $2\frac{1}{2}$ . One worker is very successful in producing landscapes with clouds, and his method is to give double the "correct" exposure and develop for half the usual time—that is, for  $1\frac{1}{4}$  minutes. These times are for the Lumière pyro-ammonia developer.

**AMIDOL.**—We use a large amount of amidol for developing bromides, and should be glad to know of anything that will allay the intense irritation of finger-tips caused by this developer.—P. C. L.

We are afraid we cannot prescribe a remedy, for such trouble is usually cured only by abandoning the developer. But the following are means of mitigating the suffering: Rub hands daily before commencing work with lanoline ("Burroughs Wellcome") so as to keep them soft. Well wash after work and again rub in lanoline, using also at times a lotion made as follows: Carbolic acid, 1 drim.; Wright's coal tar solution,  $\frac{1}{2}$  oz.; glycerine, 3 drims.; water, 12 ozs.

**SPECIMENS.**—Will you kindly inform me, through your "Answers to Correspondents," where I could secure some really high-class photographic specimens of portraiture, cabinet-size and whole-plate Imperials?—SPECIMEN.

We know of no firm which makes a special feature of supplying specimens, and possibly some would have compunction as to complying with such a request. You might try one or two of the enlarging and printing firms who work for the profession. See our advertisement pages.

**DYE PROCESS.**—Is it practicable, after staining a film of gelatine with pinatype dyes, sensitising with bichromate, and printing from a negative in place of a positive, to wash out the dye from the unaffected portions of the gelatine, and leave the hardened portions still stained. For my purpose I wish to proceed as above, but if impracticable I do not wish to waste time in experimenting.—H. F. S.

The process you suggest is on opposite lines to that of pinatype, in which process the dye stains the unexposed parts of the gelatine film. We advise you to state your requirements as to dyes to Messrs. Meister Lucius and Brünig, Hoeschst a/M., Germany, who will be able to advise you.

**J. T. T.**—Our own preference is certainly for A, since it is quicker in printing and less liable to breakage. The only advantage of V is the great equality of the light; for large negatives it would be better, but for all-round purposes the A system should give you more satisfaction.

**DEXTRINE MOUNTANT.**—Will you kindly help me, through the medium of your "Answers to Correspondents" column, in the following matter? I have recently been using a dextrine mountant made by boiling dextrine (pure white) in water, and then adding about 20 drops of oil of wintergreen to 30 ozs. of mountant. The result is generally acid, and will not keep more than a week. Should it be made alkali? If so, what is most suitable, and what preservative is most effective? Has a dextrine mountant made as above (acid), and used within a week, any ill-effects on keeping qualities of prints?—DEXTRINE.

You should use, say, three times the quantity of the oil of wintergreen. If the dextrine, through faulty manufacture, has more than a trace of acidity, the mountant should be neutralised with a little solution of carbonate of soda. We should hesitate to use acid mountant, such as you describe for P.O.P. prints, but we should not expect it to affect developed (bromide or gaslight) prints, provided they were properly washed free from hypo.

**OSBORNE, M/C.**—1. Yes, if you confine your work to bust portraits and three-quarter figures. Eighteen feet six is too short for groups and full-lengths unless a very short focus lens be employed, then the perspective will be very violent. 2. As shown in the sketch, it will if standing figures be attempted. It may, however, be somewhat ameliorated by using a diffusing screen of thin muslin at some distance from the figure 3. Buff or blue blinds will be suitable.

**J. E.**—We should recommend you to try the three following firms, who are wholesale manufacturers of this class of article: Arundel and Marshall, 27, Penn Street, Hoxton, London, N.; E. J. Brad-

street and Sons, 41, Chiswell Street, London, E.C.; Johns, Scott and Watts, Limited, 40-8, City Road, London, E.C.

**BOOK ON RETOUCHING.**—Will you be good enough to inform me the name of a small book published on retouching, finishing, and colouring; also price and where obtainable.—"FINISHER."

"Retouching," by Arthur Whiting (Dawbarn and Ward, 14, or "Retouching Negatives and Prints," by R. Johnson (Marion and Co., 2s.).

**MOUNTING ENLARGEMENTS ON THICK PAPER.**—We have had some 24 by 18 bromide enlargements made on thick rough drawing paper. We ordered them to be unmounted, as we considered the firm's charges for mounting were excessive. We have attempted to mount them ourselves with starch, but cannot get the picture to stick, since when laid on the mounts and well rubbed down they begin to rise at the edges after a few minutes, and then go off the board. Can you tell us how to do the work, as we do not care to send the pictures back to the enlargers?—A. G. AND CO.

Enlargements on thick drawing paper are not so easy to mount as small prints on thin paper, which explains the enlargement charges. However, you can do it for yourselves as follows: Make some thick starch paste and apply it evenly to the back of the picture with a sponge, rubbing it well into the paper. Allow it to rest for a few minutes to soak into the paper, and thoroughly expand it. Then apply a second coating, taking care that the edges are well covered, and lay on the mount, and well pressed contact, as in mounting small prints.

**D. V.**—Impossible for us to say, not knowing how well and how quickly you can do the things you mention. We may put it roughly at from 20s. to 25s.

**PRINTS.**—Formulae for the process have appeared in our issue of January 11, 1907.

**EMBOSSA.**—We do not know any firm, but should advise you to write Hyde and Co., 30, Duke Street, Chester, or write Messrs. Marion and Co., 22-23, Soho Square, W.C., with regard to obtaining one in Paris.

**X. Y. Z.**—We are sorry we cannot give you the address, beyond that it is in Germany. So far as we can ascertain, it has no agent in this country.

**O. O. O.**—Makers of lenses fix their own prices for them, and it is not within our province to comment upon them. You should recognise that anastigmatic lenses cannot be produced at the same price as ordinary R.R.s. Since the expiration of the Goerz patent some cheap forms of anastigmat have been put on the market, and very good they are, or such of them as have passed through our hands. Their price is moderate, and some of the dealers are in a position to allow a few days' trial of them before purchase.

**J. SIMCOX.**—From your somewhat vague description we are unable to locate the source of your trouble. If you send us two or three of the negatives we shall, no doubt, be able to assist you.

**CONSTANCE.**—Collodio-chloride prints may be blotted off with fear of injury, as the surface is as hard as that of albumen prints. They may also be dried before the fire, as there is no risk of film running. However, the prints should not be made absolutely dry, if they are dried by heat, as there may then be danger of the collodion film cracking.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

measurement of the focal length and working aperture of a lens by a method of inspection only is the subject of an article by C. Whiteley, who describes a new method and apparatus devised by him. The method can be practised by anyone, and the test requires only a minute or two. (P. 638.)

On p. 635 some notes for the encouragement of the mentally-minded worker. As is pointed out, such work can be made interesting, and the labour of entering notes of the results greatly lightened, by employing a system of codifying the notes.

E. König in a note which he sends to the "B.J.," draws attention to the advantages of the pyrocatéchine developer and to its simplicity in use. (P. 636.)

The usefulness of manipulation in regard to bromides to be sulphidised is the subject of a note on page 634.

late Mr. F. H. Wenham. We publish an account of the many inventions of the late Mr. Wenham. (P. 641.)

Austrian workers have published some results of examining photographic plates, both as to the amount of silver contained in them and as to their relative tendency to solarise. (P. 640.)

Developmental calculators, developing tanks, printing screens, cinematographs are among the patents of the week. (P. 647.)

and a half per cent. off P.O.P. Mr. G. Watmough Webster figures for the saving effected by recovering silver from fixing-liquors and wash-waters. (P. 644.)

F. C. Tilney, in an article on page 636, points out the importance of photographers (who value the fitness of their premises) of the study of antique furniture. He draws attention to the opportunity now offered at the Franco-British Exhibition of studying styles in furnishing. (P. 636.)

Photographs for the two London photographic exhibitions should be sent in within the next few days. (P. 634.)

## EX CATHEDRA.

### The Two Exhibitions.

The receiving days for the Photographic Salon and Royal Photographic Society's Exhibition are close enough upon us to deserve a final word of reminder to those who are sending to Pall Mall and the New Gallery. The only day for delivering frames by hand to the Salon is Monday, the 31st, from 10 a.m. to 6 p.m. at 5A, Pall Mall East. If this cannot be done the pictures must be sent properly packed to Messrs. W. Whiteley, Ltd., Queen's Road, Bayswater, W., by Thursday, the 27th, at the latest, marked outside, "For the Photographic Salon." In the case of the Royal this year exhibits are to be delivered by hand, not to the New Gallery as hitherto, but to Messrs. Bradley and Co., 81, Charlotte Street, Fitzroy Square, W., on Wednesday, September 2, between 10 a.m. and 6 p.m. Parcels sent by rail and carrier must arrive the day before, viz., Tuesday, September 1, also at Messrs Bradley's.

\* \* \*

### Trade Censorship of Postcards.

We are glad to see that a Postcard Printers and Publishers' Protection Association, which has been recently formed at Blackpool under the presidency of Mr. Edwin Bamforth, of Holmfirth, has been quick to place upon its list of agenda the question of prohibiting vulgar or indecent picture postcards. It suggests a preventive policy in place of—or say as an auxiliary to—the present punitive measures taken by the police. It proposes that when copyright is applied for, cards should be subjected to censorship, the grant of copyright giving the right of sale throughout the country. This proposal implies, of course, the creation of a new office akin to that of the Censor of Plays, who is, by the way, not regarded with universal favour in the theatrical world. Unfortunately, the suggested scheme breaks down in the case of cards in regard to which no application for copyright is made. Apparently, therefore, the only result would be the issue of cards of an objectionable character unprotected by copyright. In other words such cards may be copied indiscriminately, and the evil would thus be propagated.

\* \* \*

### Mounting with Gutta-percha.

A writer in a contemporary, Mr. E. R. McDonald, a short time ago advocated a method of dry-mounting prints with gutta-percha tissue, which method seems to have met with approval, seeing that some dealers are now stocking tissue for the purpose. The process is very simple, and we found it work admirably at our first attempt. Whether it is advisable as a permanent method is another question that only time and experience will determine. Indiarubber as

st. a mountant has not been a success, and whether gutta-percha is superior or not remains to be proved. The method is as follows:—A piece of thin tissue is cut slightly larger than the print, and smoothed out on a pad of damp blotting-paper, all wrinkles being rubbed out with a dry cloth. The print is laid upon the tissue face upwards, and over all is placed a sheet of clean paper rather larger than the tissue. All is then ironed down firmly with a hot flat-iron. On lifting up the print the tissue will be found firmly attached to the back, while its edges are attached to the paper cover. The margins of the print can easily be seen through the tissue, and the next step is to trim the whole just at or inside the margin, cutting through tissue, print, and paper. The paper cover is then loose, and can be removed, and all that remains to be done is to lay the backed print down on the mount, put a fresh piece of paper over it, and iron all down until the print is firmly adherent at every point. There is no trouble anywhere in the process if the instructions are followed, and the total time occupied is very short. As already pointed out, the permanency of the process has to be proved, but at the worst it is a useful quick method of mounting for prints that are only of temporary importance.

\* \* \*

#### Spots and Markings on Bromides.

In the "Information" column of the "St. Louis and Canadian Photographer," a letter from the Kodak Company attributes certain spots on some re-developed bromide prints to fixing the prints face downwards in the hypo bath. When in this position air-bells may cling to the film side and escape notice, and then various unfixed spots are left which reveal themselves if the print is subsequently treated with a bleaching solution. The application of a bleacher such as potassium ferricyanide and potassium bromide is a very good test for perfect fixing and washing, and, we may add, for finger marks due to overmuch handling of the printing paper. Very often when using the processes of sulphide toning or re-development we come across unmistakable evidences of careless manipulation of the prints, especially in the fixing bath. Spots due to air-bells are common, almost as much so as beautifully detailed finger prints. Often, too, the print shows rectangular markings, proving that it has been protected from the full action of the fixing bath by the corner of another print that has adhered to it. A most certain way of spoiling bromide or gaslight prints is to fix a number one after the other in a shallow dish containing the hypo. This is especially the case with gaslight prints, for they are made and developed so quickly that before one is fixed another is thrown in on the top of it. This is a very common cause of markings, and also of development stains. If a number of prints are to be treated a deep dish is essential, and each print should be slipped under the fixer face upwards. When the next print is ready it should be treated similarly, the previous one being turned over face down. In this way we can be certain that the film of a partially fixed print will never come into contact with a second one fresh from the developer.

\* \* \*

#### The Product of Sulphide Toning.

Many references have been made lately to the fact that the brown deposit formed by ordinary methods of sulphide toning is a colloidal compound soluble in hot water. A solution made by boiling toned images in distilled water is a deep brown in colour, and passes readily through any ordinary filter paper. Even if filtered with the aid of a pump through the hardest and closest makes of filter

papers obtainable, very little solid matter is retained, a dark brown solution is obtained that very slowly deposits silver sulphide on standing for a long time. Sheppard, in his Bolt Court lectures on "The Chemistry and Physics of Colloids," referred to the fact that earthenware filters of the kind used in bacteriology may retain the colloidal particles of a hydrosol, therefore we thought it worth while to try the effect of such a filter on a sulphide solution. We took a solution that had already been passed through a double thickness of hard filter paper and filtered it again through porcelain, with the result that a somewhat lighter coloured solution was obtained. Whether this filtrate contained any silver is not known. There is much silver than in the original solution, so that it is evident that the porcelain filter has stopped a good proportion of the colloidal particles. The colour of the filtrate may be partly due to colloidal sulphide, but it is probable that it is mainly the effect of the oxidation products of the developer originally used. On evaporating the solution to dryness a red-brown mass is produced. On treating this with nitric acid, again evaporating, and then treating with distilled water and filtering, a reddish solution is obtained which contains extremely minute traces of silver nitrate. Though small in quantity there is no doubt of its presence, therefore it appears that some of the colloidal particles must be very minute indeed.

\* \* \*

#### A Moral for Trade Photographers.

The "Fine Art Trade Journal" mentions an incident which has its parallel in the photographic trade. A picture framer received in the usual way of business some two prints for framing. They were duly framed and not called for at the time appointed. More than a month elapsed and they were still unclaimed. The framer exercised his moral, although not legal, right, and offered them for sale, for the purpose of recouping himself the cost of the framing. One of the two prints was sold, and a day or two later the vendor received a letter from a firm of publishers demanding damages for several piratical copies of a copyright picture. Of course, in such circumstances only nominal damages could be recovered, but there is all the annoyance of possible litigation and the resulting bill of costs. The moral of the story is obvious. If you do decide (as you may do) to take the law into your own hands in regard to a picture frame, an enlargement, or a miniature, beware of a worse legal pitfall.

\* \* \*

#### 'The Hon. Sec.'

The naïve suggestion is made by the Hon. Sec., that all secretaries who have been, say, ten years in office in a club of good standing should be granted the fellowship of the R.P.S. From the fact that many secretaries of provincial societies are not members of the R.P.S., and therefore cannot receive the fellowship, it may be suggested that even those who are members will probably be expected to show other qualifications than the fact that they have been secretaries of some one society for ten years. A very experienced secretary may have made no contribution to photographic knowledge, done nothing to disseminate it, and made a complete failure as a photographer. He may be an expert at organising Saturday outings, at collecting lecturers together for the winter session, and at persuading his committee and fellow members generally to follow him in all things; but these gifts are no qualifications for the fellowship of the R.P.S., even if practised

twenty years. Another suggestion is that good secretaries should receive an honorarium to induce them to retain their posts. This is as objectionable as the other suggestion is absurd. A paid secretary is one thing—he is a luxury that very few societies can afford—but an elected honorary secretary with an honorarium is a different thing altogether, and one that societies in general are wise to taboo. A point that seems to be lost sight of is the fact that it is not necessarily a good thing for a society to have the same secretary for anything like ten years. If there is only one man in the society capable of filling the post the best thing to do is to wind up the society. dependent on one man it is not worthy the name of the society or club. Two or three years is quite long enough for one man to hold the post. Longer periods work the honorary principle to death, and usually ruin the society.

## RECORDING THE RESULTS OF EXPERIMENTS.

IN spite of the many important instances of "applied photography"—and scarce a week passes but there is recorded some fresh way in which the camera is harnessed to the service of industry or of science—there are still many people who practise photography for love, not of the results they obtain, but of the processes they employ. We are prepared for the suggestion of some cynic of the "pictorial" school to the effect that in the nature of things this must be so, since the photographic product of the labours put forward by our man of processes cannot by any remote chance be of a kind to excite the admiration even of its creator. Letting the aspersion pass, it is nevertheless a cause for congratulation that there are still some whose enthusiasm is not for art, not even for a technically good photograph, but for the ways and means by which these latter are produced. We admit that in comparison with the old days his species is rare enough. The haste for prints and the short cuts by which they are obtained has turned the young generation in other directions, and the "photographer" used in the amateur sense now means something quite different from its signification, say, twenty-five or even ten years ago. Nevertheless, many of the steps towards the present state of facility were made possible—although they were rarely contemplated—by the workers whose chief interest in photography centred in the opportunity for experiment and in the fascination of obtaining a certain effect by a certain modification of the then existing methods. We would not wish to see this section of the photographic public become extinct, or swept within the walls of factories, there to work their right designs solely for commercial ends. Photography as an industry, we venture to think, is bound to suffer by the withdrawal of independent experiment, and our present object, therefore, is to drop a hint or two, solely on the practical side, which may encourage such experimental work because suggestive of means of carrying it out and recording it with less labour.

We are now writing of purely photographic experiment such as any one without systematic chemical training may well do, and therefore it will be understood that much of it will consist of treatment of various kinds applied to negatives or prints. Our first hint may, therefore, be that much labour in the way of recording what is tried and found will be saved by using some system of code by which one or two numbers pencilled on the back of the print will fully describe what has been done to it. Thus let us suppose, by way of example, that we are making experiments on sulphide toning with various leathers, various "sulphiding" formulæ, and possibly

other variations of the standard process. We will, therefore, denote one bleach formula by B1, another by B2, whilst similarly our sulphide mixtures may be denoted by S1, S2, and so on. Thus a given method of treatment is quickly pencilled on each print, thus, B2 S1, or thus, B1 M S2, this latter case corresponding, say, with the use of an intermediate bath of metabisulphite, or, if the effect of varying time of washing be in course of study, the entry may read B1 W15 S2.

A very good example of the convenience of some such system as this may be found in the paper by Mr. R. J. Wallace on orthochromatic sensitisers which we printed some month or two ago. Mr. Wallace used a key system to plan out a set of experiments conveniently, and to mark the test plates and to record the results quickly.

As regards the actual negatives to be made, the best plan, no doubt, is to make use of a graduated test strip obtained by exposure in a sector machine. But the treatment of such test strips is, perhaps, hardly the finest inducement to prosecute experimental work, and therefore we recommend a combination of a negative and test strip obtained by making each graduated patch a complete negative or positive in miniature. This can be very conveniently done by mounting a few short strips of cinematograph film on a glass plate, selecting positive or negative according to one's requirements in the plates or prints to be printed from them. The series of tiny pictures—sixteen will go on a quarter-plate—are then made of different opacity by masking with tracing paper or papier minéral, a number being written on each patch. This supplies a useful and at the same time interesting test plate from which to print off negatives or positives for treatment. If a suitable subject be selected, the pictures in, say, 10ft. of cinematograph negative or positive film may be taken as of uniform density.

As regards the actual marking of plates according to the code suggested above, perhaps the best method of all is to allow the light to impress the necessary figures at the time of the exposure. This may be done by interposing between the test plate and the sensitive emulsion a thin film of celluloid with the numbers and letters written thereon in ink. The plate is thus indelibly marked, and more easily than by writing on the film. There is, of course, no particular merit in adopting this or any other method: our reason for suggesting it is that it is quick, certain, and avoids the tedious writing on plates by hand when in the dark-room.

An alternative form of test plate that is at times very useful can be prepared with the aid of a repeating back that will produce, say, twelve small images of the same subject on a quarter-plate. A graduated series of exposures can be given, so that each image represents a different effect of exposure. Prints or copies from the resulting negative will then show the various effects of under- and over-exposure, and will be very useful for the trial of various toning methods to test the kind of negative best suited to the process.

A negative made up from cinematograph films, as before described, but without the overlay of tracing paper, is also very useful for preparing enlargements. These can afterwards be cut up and the different prints can be submitted to various methods of treatment for the sake of comparing effects.

In conclusion, we would impress all would-be experimenters with the necessity for keeping full and complete records of their experiments with the results. Too often no record is kept, especially when only unsatisfactory results have been obtained, then later on the work has either to be done again or the experimenter is tempted to rely on a vague memory of results that as often as not is quite deceptive.

## THE PYROCATECHIN DEVELOPER.

I SHOULD like to draw the attention of photographers more closely to the little-used pyrocatechin developer. Pyrocatechin, chemically is a dihydroxyphenol of the formula  $C_6H_4(OH)_2$ ; that is to say its composition is identical with that of hydroquinone; but the two compounds differ in their constitution, the relative position of the OH group in the benzene nucleus being different. Used in conjunction with potash carbonate or soda carbonate, pyrocatechin works with moderate energy as a developer, but when compounded with caustic soda or potash its action is vigorous. If one only of the hydroxyl group be saturated by addition of the correct proportion of caustic soda, a developer is obtained which behaves exactly like one prepared with the carbonate of soda or potash. If, however, the two groups are replaced by sodium or potassium by further addition of the respective caustic alkali, the action of the developer is as strong as can be desired; in fact, in the majority of cases, too powerful. Considerable experience with the developer has led me to the use of the following formula, which may be strongly recommended. An important point in compounding it is to use the caustic alkali in *exactly* the proportion given. It is better to add the caustic soda from a solution of known strength, such as is commercially obtainable. Thus, for the caustic potash solution of 32 per cent., 87.5 gms. solution is taken in place of 28 gms. of the pure (100 per cent.) solid alkali. Commercial solid caustic potash is never 100 per cent.

A. Pyrocatechin.....	55 gms.	480 grs.
Sodium sulphite cryst. ....	35 "	300 "
Water to make.....	500 ccs.	10 oz.
B. Caustic soda 100 per cent .....	28 gms.	245 grs.
Sodium sulphite crystal.....	150 "	3 oz.
Water to make.....	500 ccs.	10 oz.

The volume of each separate solution should thus be 500 ccs. To make up the developer the following proportions are taken:—

A 10 ccs.	B 10 ccs.	water 150-250 ccs.
or, A $\frac{1}{2}$ oz. (fl)	B $\frac{1}{2}$ oz. (fl)	water 4 to 6 oz.

Using the smallest proportion water given above (150 ccs. 4 ozs.) greater density is very easily obtained.

The chemist will readily see that in this developer the hydroxyl group of the pyrocatechin is entirely, and the other half, saturated. If a weaker acting developer is required, the following may be made up:—

A 15 ccs.	B, 10 ccs.	water 200 ccs.
or, A $\frac{3}{4}$ oz.	B, $\frac{1}{2}$ oz. (fl)	water 10 oz.

the composition of which, when applied to the plate, corresponds with the formula  $C_6H_4(OH)(ONa)$ . On the other hand, a more energetic developer is produced by taking solutions as follows:—

A 10 ccs.	B 15 ccs.	water 200 ccs.
or, A $\frac{1}{2}$ oz. (fl)	B $\frac{3}{4}$ oz. (fl)	water 10 oz.

This developer approximately corresponds with the formula  $C_6H_4(ONa)_2$ .

The chief advantages of the pyrocatechin developer are the excellent keeping qualities of the separate solutions, its quick action, its freedom from fog, and its ready adaptability to the constraint with potassium bromide.

Any required degree of density can be got by varying the time of development and the strength of the developer.

For the development of lantern-plates more water than indicated above should be added.

A last point which must not be lost sight of is that the sodium sulphite must be divided between the two solutions, for the reason that if too concentrated a solution is prepared an insoluble compound with the pyrocatechin is formed.

Photographers who try the above formulæ will find the pyrocatechin possesses great "Abstimbarkeit" (as we say in Germany), that is, adaptability for restraint by variation in the amount of alkali and the addition of potassium bromide.

DR. E. KÖNIG

## ANTIQUE FURNITURE AS A STUDY FOR PHOTOGRAPHERS.

WHEN the proper background has been rolled down, the armchair wheeled into position, and the balustrade effectively placed, the average portrait photographer may think he has done enough for his money in the way of the "setting" of his figures. He can scarcely be expected to throw in with "half-dozen cabs." the representations of genuine antiques in the furniture line; nor could it even be expected of him that such accessories as do appear upon his prints should be guaranteed trustworthy in all respects. Nevertheless, there is something in "style," and since artistically furnished reception rooms and studios are the fashion, it is wisdom to avoid solecism and anachronism as much as possible in these matters, lest some sitter who knows should fall foul of a Wardour Street nondescript. Everything should be cultivated that is likely to make a favourable impression upon the emotions of sitters. Clients should be made to feel interest and pleasure in their visits: they should go away with the "do it again" feeling at high pressure.

The appointments of the studio are largely concerned in the invoking of this feeling; but it by no means follows that those appointments must be costly and rare. All that is required is decent taste leaning toward the simple side, and some rudimentary knowledge of furniture and interiors historically considered. Even the history need not extend far back; but there should be knowledge enough to ensure a fitting harmony. It gives one a

shock to find an oak chest purporting to be Jacobean flanked by a gimcrack three-legged bamboo flower-vase-stand from Tarragona. If polished wood furniture is used it is as well to keep the "fumed oak" out of it altogether; and the modern "new art" contrivances will look abhorrent beside Chippendale chairs and Victorian turned work. When these objects figure in the photographer's prints the question is more important than ever. The oak chest may quite fittingly appear upon the same print as the baronial window background; but the "new art" writing-desk with heart-shaped holes sawn out of it, looks silly standing before the pictured column and looped curtain, with the thunder-cloud and lake in the distance. As a rule, when the realisation of walls, panelling, or furniture is attempted in distemper, the result is beneath criticism. These matters are a by-interest of the photographic profession, and therefore do not always receive the consideration they deserve. That there are not a few portraitists who do display a keen interest and a profound knowledge of architectural styles, in antique furniture and objets d'art, nobody denies; but as a rule the photographer is content to take on trust the baronial windows, panelling, and so forth, just as he receives them from the makers of this valuable "property," and answers the questions asked."

As to property balustrades, sundials, garden seats, and the curious pedestal arrangements which in the seventies were used

the long-suffering sitter to droop his weary hand over: all these shams, if cleverly made, may be as good photographically as the genuine things; but they are nothing for the photographer to boast about. He cannot "spread himself" about them in the lecturer's well-known way:—"Ah! I'm glad you like that. It's a fine old example of . . . There's a curious history attached to that. It caught my eye once in . . ." And so on. Supposing, however, that the object in question were an authentic appendable mahogany urn, such as may be seen at the Franco-Italian Exhibition, he might excusably enlarge upon its parts. All who are interested, or who are anxious to be interested, in a fascinating subject, might do worse than keep it in view when they are at the Shepherd's Bush exhibition. They would, of course, do infinitely better at the Wallace Gallery, and later still at South Kensington; but people do not seem to resort to those places unless they are either school children, foreign tourists, or pedantic specialists. All the world goes to "Franco," however, and therefore a special point is here made of the loan collection of furniture, which offers a fairly representative survey of historic styles.

People who have recourse to the furnished interior as a background, and who wish to know something more of the subject on the background-artist divulges, can see here the genuine modelling of a "Georgian" room; a Queen Anne room; and a William and Mary room; the last having also some real Grinling Gibbons carving *in situ*. That fact calls to mind that in another case some genuine Grinling Gibbons carving is laid out for inspection upon the floor, over a modern Oriental carpet. Such aicism would not be permitted in a continental exhibit; and it shows the difference between the rough and ready British, and more tactful Franco departments. Messrs. Hamptons atone this by their excellently carried out model—copy, rather—at scale of two-thirds, of the great Banqueting Hall at Hatfield. This is the feeling and colour of the monumental style of a past is quite convincing. It suffers only in one respect perhaps, namely, that the genuine pieces of furniture which it sets off, of course, not at two-thirds scale, and, therefore, the Hall itself, spacious and lofty as it is, looks like a good sized room with *petite* Tudor embellishments. Among other reproductions of worth examination are the work-table of Louis XVI. and "Tenture" of Marie Antoinette; that is, the tent-like hangings that were disposed longwise over the couches and beds of this period, and fell from a crown arrangement above the head on the right side and over the feet on the left. The historical interest of some of the loan exhibits should not make them worth a visit to people concerned with pictorial matters. Such are the immense chairs of the "masters" of certain city companies; the Knole chair, wherein James I., most dread Sovereign, sat for his portrait, as well as other pieces remarkable for grace of form, ingenuity of construction, or striking associations: the gun of Alexander Selkirk for example.

There are five priceless Gobelin Tapestries, of the time of Louis XIV., almost worth their weight in gold, and "d'un goût ravissant," though perhaps in these advanced days their assessment is a little elusive. But the modes and methods of the romantic past are not only charming and interest in themselves. To photographers who are concerned with pictorial representation, either in theatrical photography or for the mere love of the art of the past, they are a never-ending study. Such students will find this part of the exhibition of distinct value. The lighter and fanciful rococo, the heavier "baroque," both disposed to kick over the heels at times, but charming in their wantonness; the seemingly propriety of "renaissance" of all kinds, of which differing expressions may be compared in some of the buildings in the grounds, and the little bit of real stuff in the Georgian room; "Queen Anne" style, with its tapestry upholstery, and its politude which had not arrived at Georgian grace; the

"William and Mary" style, revelling in surface decoration and japanning; the mighty "Stuart," just the reverse of Stuart costume, which was frivolous; all this is highly educative, and to go through it with a purpose in view is far less fatiguing than to adopt the too common museum slouch which says so eloquently "all this old stuff doesn't interest me."

When once the Rubicon is crossed the subject becomes fascinating. Surely it is of interest to know, for example, that the Greek chair with its legs curving out, upon which our professional beauties so often disport in so-called classic garb, owes its design to the elephants' tusks which originally served it for legs. It is *sui generis*, the legs of the couches of this period being invariably turned and of short proportion. Would it not surprise some to learn that we were importing Norway pines and Oriental carpets in the thirteenth century? In those days there were no banks, so the treasure was kept in chests. Upon these chests folk sat, ate, slept, worked, and played. No wonder there are still plenty about, for they held on till much more recent times. In the very old days there was little else in the way of furniture, except wondrous bedsteads and tresselled dining tables for the wealthy. By the development of a back the chest became a settle; by developing legs it was becoming a cabinet. The amateur who photographs in cathedrals occasionally sees large semicircular chests. Does he guess that these are cope-chests in which the bedizen copes were spread out flat one over the other? It will have been noticed that woodwork was embellished with architectural design—window tracery in Gothic times, and later, all the elaborations of classic architecture. When this is understood the Wardour Street chip-carving antique will be suspicioned.

With the renaissance and its imitation architectural façades in furniture, sculptured figures came into fashion, and the sixteenth century saw the culmination of the beautiful art of sculptured wood. Venice set another fashion, that of gilding furniture, and marquetry flourished under William and Mary. But the most astounding feats in cabinet work were performed under the patronage of Louis XIV., who established the "Gobelins" tapestry factory and pressed all the available talent and skill into his service for the production of great and exquisite work. The name of Boulle is famous for the employment of tortoiseshell and brass in the manufacture of tables, consoles, and armoires. Boulle work did not supplant the oak of Tudor time until a century later in England, where the carving of Grinling Gibbons and the architecture of Wren were contemporary. The former is remarkable for its absolutely sure cutting of immense swags of fruit and flowers, in soft wood, with a precision and ease and dexterity that will perhaps never be surpassed. The seventeenth century in France brought a new development. This was the Rococo (*rocaille coquille*), a style of ornament suggested by the shapes and curves of rocks and shells. Its lowest and latest debasement may be seen in the decorations adopted by a well-known firm of restaurateurs, and there is much of a bad sort in the bandstands and similar erections at Shepherd's Bush, where its first cousin, the Baroque, is also rampant. But let not these wholesale conglomerations of nondescript curlywigs be thought proper examples of the rococo. It has been the fashion ever since the formation of the Morris cult and during the reign of the arid "new art" to turn with repugnance from everything that flourished under Le Roi Soleil, and rococo has been the pet abomination of every one aspiring to "culchar." The attempt to design a piece is a wholesome corrective of this nausea. The style has certainly been frightfully abused, because it is so easy of abuse. Its inconsequence and want of "growth" has made it anathema at South Kensington, where ornament is only recognised as such when it pretends to be a vegetable. The finest rococo work has a grace and charm, and a freedom from logical obligations (which are millstones) unsurpassed by any pure system of ornament since the days of savagery, when ornament was purest of all. Its curves and conformations display to the best

advantage the heavy, thick, and pure gold with which it was covered in the days of Berain. The eighteenth century gave us Chippendale, Sheraton, Heppelwhite, the brothers Adam, and others, the characteristics of whose work are fairly well-known. These times produced craftsmanship which it seems hopeless to look for again. The wood they employed, the taste and grace displayed in design, the perfection of workmanship, the lightness

and strength which appears to defy time, the marvellous ingenuity of construction that permitted surprises and acrobatics almost automatically on the part of a piece of furniture and the smoothness and firmness of all such action: these are the most obvious characteristics of cabinet work of a past day when the labourer loved the work of his hand and made of it veritably a fine art.

F. C. TILNEY

## A SCALE LENS METER.

In the "B.J." for April 17 I described a very simple method of measuring the effective diaphragm aperture with the aid of a graduated scale laid across the lens hood, but the article had no sooner appeared than it became evident to me that this method of using a scale was capable of amplification, and that by the use of scales both in front and behind the lens it should be possible to measure not merely the effective aperture, but also the  $f$  number of the aperture and the focal length. The principles upon which this method of measurement depend are as follows:—

In Fig. 1 *L* is a diagrammatic representation of an objective, and against its hood is placed a broad divided scale *H* of the type described in my former article. The edges of the stop aperture *ss* can be sighted along the lines *a* and *b* in the manner described before, and thus we can determine the effective aperture to be a little over 1.7 inches, say 1.72. The scale can be

division on the first scale *C* and the fifteenth on the second, *D*, will appear to be in alignment with the right hand edge of the aperture. Similarly, when we sight along *b*, the 43rd division on *C* and the 36th on *D* will appear to be in alignment with the left-hand edge. We can therefore see 43 - 8, or 35 divisions of the scale *C*, and 36 - 15, or 21 divisions, of the second scale *D*. In other words, we see 14 divisions more on the first scale *C* than on the second *D*.

If from *o* on scale *D* we draw the line *or*, parallel with *np*, this will intersect *C* at *r* at the 29th division, and the distance *rm* is then 14 divisions, or equal to the difference between the amounts of each scale that we can see through the lens. It is obvious that the angle *mor* is then equal to the angle *ofp*, that is to say, *mor* is equal to the angular aperture of the lens. If, now we know the distance between the two scales *C* and *D*, and into this distance divide the distance *mr*, we obtain the

Fig. 1.

assumed to show inches and tenths, and it is evident that the aperture extends from the .6 division to a little beyond the 2.3 division, say 2.32, so that the total width is  $2.32 - .6$ , or 1.72 in.

Now, from the first principles of a lens action, it is clear that when we are looking along the lines *a* and *b* we are directly sighting the principal focus, *F*, of the lens. That is, if we put a point at *F*, it will appear directly in alignment with the edges of the stop aperture when we sight along *a* and *b*. The lines or rays along which we are sighting appear to be continuously parallel, though they are actually refracted by the lens so as to converge on to the point *F*.

Suppose we place at *C* and *D* behind the lens two exactly similar equally divided scales *C* and *D*. It is evident that the converging lines of sight will intersect *C* at *m* and *n* and *D* at *o* and *p*. We shall therefore see more of the first scale than of the second. When we sight along the line *a* on scale *H*, the eighth

number of the angular aperture. In the diagram the separation of the scales is equal to 50 divisions on either of them, therefore

the  $f$  number is  $\frac{50}{14}$ , or 3.57.

We have already measured the effective aperture on scale *H* and found it to be 1.72 inches. If we multiply this by the  $f$  number, we obtain the focal length, which works out at 6.3 inches in our example.

It is clear that there is a small error here. We are finding the focal length by multiplying the effective aperture not by the  $f$  number of the effective aperture, but by that of the angular aperture. These are not necessarily exactly the same, but in ordinary cases the difference is so small that it can be neglected quite justifiably. The error, if any, is in focal length only. The  $f$  number of the angular aperture is correct, and this

most important factor that we want to know. In fact, when apply any one of the various well-known methods of finding focal length, we only do so with the idea of ultimately finding the  $f$  number of the effective aperture, which we only obtain more or less approximately. The angular aperture is of greater importance, and by the method described in this article we obtain this in the first instance, and with a very close degree of accuracy.

On these principles we can devise a very simple and compact apparatus for measuring lenses, and the two next diagrams suggest

Fig. 2.

at a form which could be constructed very easily and at small cost.

In Fig. 2 we have a section of the lens meter. A is the base-board carrying the scale D, and scale C is mounted on a table B fixed at a definite known height above A and carried on vertical supports, SS, fixed at the angles. G is a second table, fixed on SS, TT, that telescope into SS. The distance between G and B can thus be regulated to exactly fit the objective, which is placed between them as shown.

Slots are cut in G and B, so that we can sight right through them past the scale C on to the scale D, and the scale H can be fixed vertically above the slot in G.

In Fig. 3 the apparatus is shown more fully in isometrical projection, and here a V is shown fixed to the upper side of B and the under side of G, so as to enable the objective to be exactly centred over the edges of the scales. The scale H is fitted with a vernier to permit accurate reading of the effective aperture, and the arrangement is rather more complex than the simple scale before described. E and F are two blocks that slide along the board N, which is fixed permanently at right angles to G.

Fig. 3.

The scale H is attached to E, and moves with it, while the vernier is on the edge of F. The edges of the aperture are sighted along the lines ss ss, which can have small point sights at both ends, and if we first adjust E to bring ss in alignment with the edge of the aperture, and then similarly adjust F, the effective aperture can be read directly off the scale and vernier. The apparatus can be used in an upright position, as shown, and a person with good near sight will find no difficulty in reading the scales beyond the lens. If, however, such a difficulty is felt, it can be got over very easily by using a simple magnifier or reading lens. The scales C and D can be very finely divided, especially if a magnifier be used.

C. WELBORNE PIPER.

# SILVER IN COMMERCIAL DRY-PLATES AND THE LIMITS OF REVERSAL OF MODERN PLATES.

[Under this title we translate two papers which appear in the current issue of "Photographische Korrespondenz."—Eps. "B. J."] In the course of examining a so-called reversal-free plate it was observed that the ordinary rapid plate used for comparison with that of the special make showed much less tendency to solarisation than that specially prepared for the purpose. On repeating the experiment with a comparison plate of other origin it was found that in this case the reversal-free plate solarised at a later point than the ordinary plate. The limits of reversal of the two comparison plates must therefore be very different, and on a suggestion of Dr. J. M. Eder experiments were made with various commercial plates, in order to discover the number of meter-second-candles necessary in order to produce a clearly graduated reversal.

In a previous paper on reversal phenomena Eder has emphasised the fact that the amount of light necessary to cause reversal varies with different plates.<sup>1</sup> These numbers are, in fact, so widely separated in the case of seven different makes of plate that they fall between 15,000 meter-second-candles and 247,000. These numbers are only approximate, as time did not permit of an absolutely correct estimate, and further, such exact figures are of little interest, in view of the very great differences observed. It is to be noted that among the various rapid plates it is not the most sensitive which solarises most easily. Differences in the limits of solarisation must evidently be ascribed to something else than the sensitiveness. The dyes added to the emulsion no doubt play an unimportant part in the instances noticed, as the plates were not at all, or very weakly, dyed; at any rate non-orthochromatic in the ordinary sense. The emulsions with the smallest and highest solarisation limits were not sensitised according to the spectroscopic tests, their deep yellow colour being due to a high percentage of soda-iodide. The observation that silver-iodide favours solarisation of gelatinobromide of silver emulsions is in agreement with the experiments of Schumann.<sup>2</sup> We found that addition of potassium iodide to the emulsion before coating favoured the reversal of the image.

The exposures were made by means of a Welsbach burner and a Chapman Jones sensitometer. The Welsbach burner was found to be burning quite constantly during a time of two days. Its actinic value was obtained by comparison with a Hefner amyl-acetate lamp, and was found to be in two experiments 322 candles. The absolute light value in the different portions of the Chapman Jones sensitometer was ascertained as follows:—

(<sup>1</sup>) "Photographische Korrespondenz," 1902. Page 645.  
(<sup>2</sup>) Eder's "Jahrbuch," 1898. Page 391.

## ON THE QUANTITY OF SILVER SALTS IN COMMERCIAL DRY-PLATES.

In the course of the above experimental work it became of interest to us to ascertain the proportion of silver salt to gelatine in the modern highly sensitive emulsions, which data may possibly be of interest to others. Very few particulars as to the proportion of silver bromide to gelatine in commercial plates are to be found in photographic literature.<sup>4</sup> Hurter and Driffeld give the proportion of silver bromide as from 26 to 49 per cent. It appeared to us, however, of importance to consider whether the highly sensitive dry plates may not contain either too little or too much silver bromide. In order to obtain a negative of full density in the case of a plate containing very little silver halide there is the obvious necessity of a thick coating of emulsion. We have, however, observed that plates differ very greatly in the amount of emulsion which they carry. These variations, in the case of commercial plates, have amounted to from .425 to .627 gms. of emulsion per 100 sq. cm. An appreciably less proportion of silver bromide in the emulsion would not be compensated for by increasing the proportion of emulsion upon the plate in similar degree, and the plates would necessarily give weak nega-

(<sup>4</sup>) Eder's, "Handbuch der Photographie." Vol. III. Fifth edition. Page 76.

Half of a plate was exposed with the Scheiner sensitometer to the standard benzine lamp at a distance of one-third meter to one minute; the other was likewise exposed to the same lamp but behind a Chapman Jones sensitometer at a distance of half meter for 20 minutes. The following equal densities were then obtained—

Chapman Jones .....	15	...	14	...	13	...	12
Scheiner .....	12	...	10	...	8½	...	7

The absolute light values obtained by means of the Scheiner sensitometer in the various areas are known<sup>3</sup>, and by comparison of the corresponding densities the absolute light values of the respective areas of the Chapman Jones sensitometer were ascertained. This was confirmed as follows. Two different experiments gave approximately co-incident results. For a Hefner amyl-acetate lamp, the actinic brightness of which was 13.1 times as great as the Scheiner benzine lamp, the absolute light intensities of the various areas of the Chapman Jones sensitometer correspond to a distance of one meter and a time of exposure of one minute, that is as follows:—

Batch No. ....	16	15	14	13	12	11	10	9
Meter-second-candles .....	0.10	0.15	0.2	0.3	0.4	0.6	0.8	1.2
Batch No. ....	8	7	6	5	4	3	2	1
Meter-second-candles .....	1.6	2.4	3.2	4.8	6.4	9.6	12.8	19.2

The comparison plates were exposed to the Welsbach burner for one hour at one meter distance, and the reversed results, as well as the neutral effect, observed. The results obtained are given in the following table:—

Description of Plate.	Patch of Chapman Jones Sensitometer in which Reversal Begins.	Light (in Candle-meter-seconds) required for Reversal
German Plate I. ....	10	15,000
German Plate II. ....	2	247,000
Austrian Plate I. ....	6	62,000
Austrian Plate II. ....	9	23,000
English Plate I. ....	10	15,000
English Plate II. ....	7	46,000
French Plate. ....	6	62,000

From these figures it will be seen that the limits of reversal of the different plates now obtainable commercially show such great differences that attention may well be given to the technical means which can be used for the avoidance of this property in plate.

DR. H. TAPPEN.

(<sup>3</sup>) Eder's "Handbuch." Vol. III. Fifth edition. Page 215.

tives. For this reason the comparatively small proportion of silver halide given by Hurter and Driffeld appeared improbable in the case of the modern plates.

On the other hand, we have noticed in many experiments that emulsions which contain a large proportion of silver salts decompose extremely easily on long digestion by heat, to such an extent that the characteristic grain disappears, whilst emulsion with less silver bromide show a similar change less easily. As the modern ultra rapid plates are no doubt the result both of longer digestion and a higher temperature than formerly, it would appear that a very high proportion of silver salt is inadvisable in practice, apart from the fact that the dry-plate maker is anxious on the question of expense to use as little as possible of the silver salt.

The above anticipations have been confirmed by analysis. We found in the case of seven different varieties of commercial plates a proportion of silver halide of from 40 to 46 per cent; only one plate of Austrian origin had 36 per cent. This was evidently coated by hand, and had .346 gms. emulsion per 100 sq. cm.; it thus differed markedly from other makes.

All the analyses of the plates were carried out in the same way. About 200 ccs. of the emulsion was carefully measured and weighed when air-dry. It was then dried for two hours at 105 deg. C, in order to estimate the percentage of water, and then heated to 70 or 80 deg. C in a mixture of 100 ccs. of water and 10 ccs. nitric acid of 1.4 sp. gr., until the whole of the silver salt had precipitated. This precipitate was then dried on a Gooch crucible, washed with water and alcohol, dried at 140 deg. C to a constant weight. The following were the results obtained:—

Description of Plate.	Area in sq. cms.	Emulsion gms.	Water gms.	Silver halides gms.

Austrian Plates III.....	0.3463	9.59	36.38	63.62

The fact that so few varieties of plates from the great number upon the market have been chosen may, perhaps, be remarked upon. We have, however, chosen the best-known and most widely used rapid emulsions, and it may perhaps be assumed that in general the proportion of silver salts in the modern dry plates lie between the limits above given.

TH. REKASCHOW.

## THE LATE F. H. WENHAM.

the person of Francis Herbert Wenham, whose death we recorded in our last issue, the scientific world loses one of the most notable and original workers of the last century. For Mr. Wenham, well known as he was in scientific circles fifteen or twenty years ago, had largely outlived his reputation, though his sudden death at Folkestone early last week will have come as a shock to many who were intimately associated with him before his retirement from active life.

Born in Kensington in 1824, the son of an army surgeon, Mr. Wenham in boyhood developed decided mechanical tastes, and as a boy experimented with various devices. At the age of fifteen, after the death of his father, he entered a marine engineering firm at Bristol as a pupil, where he remained for five years. His introduction to engineering was with a firm which undertook the forging of the crank shaft of the steamship "Great Eastern," one of the earliest steam vessels in the Atlantic trade. It was a fact that the aid of James Nasmyth was called in, for this was the first work, to install a steam hammer in place of manual labour, and to an introduction of Nasmyth to Wenham, resulting in a friendship which lasted until the death of Mr. Nasmyth forty years afterwards. During this time Mr. Nasmyth took great interest in many of Mr. Wenham's later inventions.

Mr. Wenham's first work on the completion of his time at Bristol was a series of experiments on high pressure steam in tubular boilers for marine engines. The outcome of this was that he designed and, with the assistance of two mechanics, himself built a small steamer, on a backwater of the Thames, working at a pressure of 300lb. per square inch instead of the average maximum of 60lb. adopted at that time. He also adapted to the little steamer a greatly improved type of marine engine. The little vessel proved productive of some notable photographic results, for the late Mr. F. Frith, of Reigate, the founder of the well-known view publishing house which still bears his name, entered into an arrangement with Mr. Wenham to use the vessel out to Egypt, and make a trip up the Nile as far as the Second Cataract. This was in the year 1853, and the two travellers, accompanied by two other friends, were thus the first to undertake the taking of a series of photographs of Egyptian tombs and scenery by the wet collodion process, then first introduced by Scott Archer. It says something for the rapidity of Mr. Wenham, and his confidence in the newly introduced vessel, that he himself, with one assistant, sailed it by the Thames and the Woking Canal to Southampton and

thence around the Lizard to Liverpool, where it was shipped on board a Mediterranean steamer to Alexandria. The voyage up the Nile included a visit to notable places of interest, and afforded plenty of opportunities for an inventive genius such as Mr. Wenham was. Thus many of the dark tombs were lighted by means of mirrors, which reflected and re-reflected the outside daylight to an extent which allowed of the inscriptions on the walls being photographed. Not only that, but the very food of the party had at times to be provided by Mr. Wenham, who years afterwards was accustomed to relate how his shot-gun and rifle found food for his companions, who were often glad to consume tough ducks and even curried young crocodiles. The present luxurious user of Kodak films and dry-plates can have little idea of the labours of the early collodion worker who, for example, would find his work stopped by a bottle of collodion evaporating with a short rapid fizz in a hot climate such as Egypt. On the return of the steamer to Alexandria, the reigning Pasha, Mohammed Ali, on hearing of the exploits of the steamer, offered to purchase her, provided that the vessel was certified as safe and reliable by the Pasha's Scotch engineer, and that the cabin door was enlarged sufficiently to allow the Pasha, an enormously stout man, to enter. The second condition was more easily fulfilled than the first, for the 300lb. pressure marine boiler was such an innovation at that time that great difficulty was found in convincing the engineer of its safety, which, however, was finally accomplished.

The photographic tour was prolonged to the Holy Land through the Desert by way of Mount Sinai, and afterwards through Jerusalem and Damascus to Beyrout. The series of photographs of both Egypt and Palestine, on their publication in London, had a large sale, and possibly were the first photographs to be publicly issued from collodion negatives.

On his return to England, Mr. Wenham was made director of the Panopticon of Science, an institution of popular recreation, which had a very short career owing to disputes among the proprietors. It was here that, amongst other photographic work, he constructed a special apparatus for enlarging, a method which at that time was practically unknown. The Panopticon stood on the site of the present Alhambra Theatre in Leicester Square.

Mr. Wenham next entered into partnership with a well-known engineer in Battersea, where he designed a gas-engine, which is believed to have been the first engine of its kind in

str  
this country. On the patent for this invention being found to conflict with a prior engine, the manufacture was discontinued, and Mr. Wenham then worked out and patented a hot-air engine, which, on discontinuing his partnership and entering into business on his own account, he raised to a high pitch of perfection. Several of these engines are still in use for pumping purposes. The next important invention was that of the compound principle in marine steam-engines, by the use of an auxiliary cylinder for superheating steam. The system was a great practical success, and enabled steamers trading between the South American States and the Clyde with cotton to travel twenty miles per hour instead of fifteen or sixteen as formerly, and to thus serve as blockade-runners at the time of the American Civil War. Unfortunately, it was discovered that a method somewhat similar in theory had been

THE LATE F. H. WENHAM.

published in the early part of the century by another inventor for a different class of vessel; and Mr. Wenham, who throughout his life would never take disputes as to his inventions into the law courts, turned his attention to other branches of applied science.

Whilst still engaged in his engineering pursuits, purely scientific studies, and optics in particular, had interested him for years previously. Many instruments and accessories, more especially for microscopic work, such as the binocular microscope, the paraboloid, etc., were now invented by him, and were described in numerous papers read before the microscopical societies. Perhaps the most important of Mr. Wenham's inventions at the time was the binocular microscope and the replacement in microscope objectives by single front, of the triple front as had been used previously. Mr. Wenham was at

this time engaged in constructing a 1-50th inch objective finding great difficulty in making a triple front of such minute size for this objective, it occurred to him to use a single front, and make the necessary corrections in the positive and middle combinations. He was greatly surprised at the result, but he found that it was absolutely necessary the single front should be of a specified thickness to obtain proper corrections of the whole of the objective. This was the first time that thickness had formed an element in correcting objectives. Mr. Wenham generally brought his inventions before the Microscopical and Optical Societies; but opticians of that time were chary in adopting new systems until an eminent firm became convinced of the simplicity and superiority of Mr. Wenham's inventions and publicly adopted them. All opticians followed suit, and in a very short time the triple objective fronts were obsolete, and binocular microscopes were highly popular in England and America, and remained so until the great change in microscopes introduced by Professor Abbe.

During this period he occupied the position of Vice-President of the Microscopical Society.

It may be here stated that the now popular oil immersion which has been brought to such perfection by the great German of Professor Abbe, was originally brought to the notice of the Microscopical Society by Mr. Wenham. He actually showed one of their meetings an objective which he termed a homogeneous lens, i.e., a lens attached to a threefold objective the cover glass of the object kept in contact with this lens by means of cedar oil. Mr. Wenham showed the object angulatum brilliantly defined by this oil-immersion objective, but, unfortunately, he did not at the time realize the great importance of the oil-immersion system in the matter of yielding greatly increased numerical aperture. A few years afterwards oil immersion was brought to the notice of the late Professor Abbe by the late Mr. Stevenson, with the result that the great mathematician worked out the perfect immersion systems now so universally adopted, and they for many years past entirely superseded water-immersion lenses.

In 1870 Mr. Wenham withdrew from the engineering business and on the death of Mr. Thomas Ross in 1870, being urged by his old friend Mr. Shadbolt, accepted the position of scientific adviser to the firm of Ross and Co. He here made many improvements in the microscopes and accessories produced by that firm. But his connection with Ross will perhaps be better remembered by his introduction of the once well-known Portable Symmetrical lenses. These lenses were an adaptation of Grubb's well-known Landscape lenses, produced by reducing the diameters, combining the lenses as doublets, and by using thickness as an element in their correction, thus obtaining diaphragms in close contact with the lens and giving great angle of view. These lenses were produced in a series of all fitting the same flange, and became exceedingly popular with landscape photographers; in fact, they entirely displaced the old single lenses of that period. Mr. Wenham never claimed anything original in the construction, always giving credit to Mr. Grubb for the main invention of a lens in which the flint was placed outside. He simply claimed that he brought the same lens out in a doublet and more portable form.

At this time Mr. Wenham entered into controversy with another well-known optician in regard to the Aplanatic lens which had been claimed as an English production. In his pages Mr. Wenham made it perfectly clear that this lens was a production of Steinheil of Munich, and that the English production was absolutely similar, except that it was composed of slightly different glasses.

Mr. Wenham remained as scientific adviser with Ross and Co. for about ten years, and on his retirement was replaced

Mr. Schroeder, the inventor of the concentric lens (the first of the modern anastigmats). While with Ross and Co. Mr. Wenham invented the well-known Wenham Shadowless (downward burning) Gas Lamp, which attained great success, not only in England, but in Europe and America. This lamp held the field in gas lighting until it was practically superseded by the electric light and the Welsbach lamps which came on the market some years afterwards.

It may also be stated that Mr. Wenham, while on the Council of the Aeronautical Society, of which his old friend Mr. Glaisher, F.R.S., also president of the R.P.S., was president, wrote many important papers on aeronautical subjects, and made many designs of aeroplanes, adopting as his model the flight of birds. It was very gratifying to him

a short time ago to receive high commendation from distinguished Americans engaged in aeronautical pursuits, to the effect that his writings and designs were being much discussed and followed up in America.

Mr. Wenham, finding his health somewhat shaken, and having private means, retired to Woking, where he devoted himself to mechanical experiments, including an improved piano-player, which he designed long before the American piano-players were thought of. Many notes and letters from his pen appeared in the scientific and mechanical Press during this period. His advice and help were constantly at the disposal of his fellows.

Mr. Wenham's health had for some time past been impaired, and his death, at Folkestone, on August 11, was due to heart failure. He had reached the ripe old age of eighty-five.

## THE SIZE OF STEREOSCOPIC PRINTS.

[The Permanent Commission of the Congress of Photography has been attacked by M. Chapellier recently in the "Photo-Revue" with a proposal to modify the recommendations made in 1891 relative to the size of stereoscopic prints. M. Chapellier observes that the apparatus actually used gives images of a very different size from those to which these recommendations apply, and that, therefore, these latter should be revised. In the following paper Dr. Moritz von Rohr, of Jena, who is a member of the Permanent Commission of the Congress and is, moreover, the greatest living authority on the optics of stereoscopy, has communicated in the "Photo-Revue" the following reply to M. Chapellier.]

With regard to the question of the form which should be prescribed for stereoscopic prints or transparencies, it is advisable first to take a brief glance over the history of the development of the stereoscope. So far as concerns the earliest period, it can be said that it commenced to be interesting about 1851, at the time when J. Duboscq first devised, in accordance with the wishes of Sir David Brewster, a really useful stereoscope. The problem which he sought to solve in this instrument was that of fitting two relatively large images by making use of the effect of prismatic deviation of lenses acting excentrically. He attempted to do this in a convenient manner and without obvious defects, and in these conditions no limit was imposed on the sizes of the images. Under the influence, however, of the English photographers, who at that time were extremely active, the size of  $8 \times 8$  cm. was fixed as the standard for the stereoscopic picture, dimensions which involved between homologous points at an infinite distance a separation of at least 80 mm., the minimum corresponding to the case where one exactly superimposed the inside edges of the two elements. Duboscq adopted as eye-piece lenses of 80 mm. focal length, and was thus able to attain the double purpose which he had in view. This is not the place to refer to the heteromorphic effects inevitable under these conditions and common to the majority of stereoscopic prints.

The size of the image not being limited by theory, it happened at departures were made from the above dimensions either by separating one or other of the two elements or by making them larger than 80 mm. (a distance of 105 mm. has been reached between homologous points), or, what amounted to the same thing, the English dimensions were strictly adhered to, but eye-pieces of shorter focal length were employed, at any rate in England. But this led inevitably to an increase in the defects which the prismatic effect necessary for the assemblage of the images involved, that is to say, distortion by the prisms and chromatic aberrations of the single lenses.

It was only much later in this early period that opposition was made to the form given by Brewster to the stereoscope. This opposition took into account not only the optical defects of the system, but also the unnatural character of the sensation obtained (distortion in the impression of depth or of length). Towards 1860 there was an unconscious and progressive return to the suggestion made by Charles Wheatstone in 1852. According to this, the eye-pieces should act centrally in such a way that the centres of the single images of the eye-piece and of the eye

(or more particularly the centre of rotation of the eye) should all lie in the same line at right angles to the plane of the picture, that is to say, in fact, the optical axis of the eye-piece.

Unfortunately the putting into practice of this perfectly correct idea is rendered difficult by the fact that the distance of the eyes varies greatly among observers, the extreme limits being about 52 mm. and 72 mm. According to measurements of M. A. Gullstrand, who writes with authority on this subject, it can be said that the highest values of the inter-ocular separation are met with in Teutonic countries, whilst the lowest are in England and America. In any case, however, the separation is a variable quantity, and one is therefore logically led by the principle of Wheatstone to the following conclusion:—If the stereoscope is to be used by observers not having the same separation of the eyes as the possessor of the instrument it is necessary to give up the idea of the correct solid representation of the elements of the stereoscopic image and to adopt an arrangement similar to that of the double Verant.

The Commission obviously could not take into consideration such instruments as the latter, as they are of a special character, and for the great body of amateurs there is no doubt that it is the prismatic stereoscope of Brewster that is to be considered. On the other hand, the innumerable stereoscopic prints are made for this type of stereoscope, the two prints can be conveniently arranged on a single support, and, lastly, the union of the pictures is obtained most easily by persons having different separation of the eyes and using different portions of eye-pieces more or less excentric.

Therefore, it is quite permissible for the Commission to endeavour by its recommendations to reduce, as far as possible, the defects strongly marked in this very popular type of stereoscope.

There is thus reason to adopt for the separation of homologous points of objects at infinite distance, that is to say, for the breadth of the separate prints when these latter are exactly juxtaposed, a maximum of 80 mm. If one drops below this distance, say to 72 or 75 mm., the prismatic effect of the half-lenses of Brewster will be reduced, and the quality of the image will gain thereby. As for the height, the aberrations of the usual lenses will not allow of its exceeding 80 mm., or with the square form of  $80 \times 80$  may be taken as the extreme dimension of the print. One can, therefore, in principle admit all sizes which can be inserted in the square space formed by the juxtaposition of two squares having a side of 80 mm. The homologous points

of infinitely distant objects being in no case further apart than 80 mm., and being preferably less widely separated. The lenses should be mounted in such a way that the separation of their optical centres correspond to that of the homologous points, that is to say, a maximum of 80 mm., or if it is variable it can be placed at this value. For the sake of persons of small ocular separation the diameter of the half-lenses should not be too much reduced.

The focal length of the eye-pieces should not be too short, particularly if a picture of the maximum size, 2 x 8 x 8, is being

observed. A minimum of 160 mm. may be fairly taken. Under these conditions the excentricity for eyes of 64 mm. separation

is  $\frac{80-64}{2} = 8$  mm., and it seems that for a separation

average eyes a relative excentricity of  $\frac{8}{160}$  or  $\frac{1}{20}$  cannot

advantageously exceeded.

MORITZ VON ROHR

## QUICK METHODS OF TAKING OFF PRINTS.

[A useful reminder of the methods which may be used when preparing prints at short notice is contained in a recent article in the "Wiener Mitteilungen," where the author, Herr Max Frank, feelingly remarks upon the necessity of having such facilities, not only for press work, but on such occasions as the taking of a wedding group, where proofs are required to be submitted before the responsible for the order take up their departure to an unknown address.—Eds. "B.J."]

In the choice of rapid methods for the making of prints the photographer must naturally be guided by his requirements, that is to say, whether he requires one or several prints, and also whether the print is required only for temporary purposes or whether it should be permanent. If only one print is required perhaps the best plan is to develop the plate in the ordinary way, to rinse it carefully, and then to place it at once in a 3 to 4 per cent. solution of acetic acid. In the meantime, a piece of bromide paper is placed in water to soften, and is then brought in contact with the unfixed and still wet negative by aid of a few light strokes from the squeegee in order to remove air bubbles from between the two surfaces. The paper is then exposed to light in the ordinary way, except for the fact that the exposure must be from three to four times as long as that usually given, the silver bromide left in the film naturally obstructing a good deal more light. The bromide paper can then be immediately taken off the negative and developed, fixed, and washed as usual, and dried by the aid of spirit, all within a few minutes. The exposure of the negative to light being for such a short time, there is no need to fear any fogging action upon the unremoved silver bromide, particularly as the bulk of the developer is removed by rinsing, and any traces left in the film rendered inert by the action of the acetic acid.

Several copies may be made by the above method, but it is to be advised in that case to first fix the negative and thoroughly rinse it. In order to obtain the most rapid fixation the quick-acting fixing bath recently placed upon the market, which owes its properties to the addition of ammonium chloride, may be employed, or the following formula, recently given in "La Photographie des Couleurs," may be adopted:—

Hypo (anhydrous) .....	113 gms. ....	4 ozs.
Ammonium chloride .....	75.5 gms. ....	2½ ozs.
Potass metabisulphite .....	11.5 gms. ....	½ oz.

This mixture should be dissolved in 5 parts of water, or, if to be

used for bromide paper, in 8 to 10 parts.\* This fixing bath has advantage, not only of rapidly fixing the plate, but also rendering easier to remove the last traces of the fixing compound in the wash water. An aid to the rapid removal of the hypo may also be found in one or other of the hypo eliminators.

Among the most convenient and easily controlled hypo eliminators is the little used permanganate of potash. A 2 per cent. solution is made up, and about ten drops or so added to one litre of water, giving a pink solution, which is applied to plates or prints once, twice, or three times, as may be necessary, so long as the pink colour is discharged. As soon as the solution, on remaining on the negative or prints for one minute, retains its colour the photographer knows that the hypo in the prints has been destroyed, a short rinse in water is then only necessary to complete the process.

Another means of taking off prints rapidly from the negative consists in the use of thin celluloid, such as is used in the manufacture of roll-film. A sheet of convenient size is laid upon the negative, pressed down with a squeegee, when prints may be taken off on bromide paper, which is laid in contact with the upper side of the protected celluloid film. The latter, after printing is finished, is at once removed without having injured the negative in any way. In this, as in other methods of printing from the wet negative, attention should be given to drying, with a soft duster, the glass side of the negative, otherwise markings and spots are liable to occur in print, owing to the adherence of drops of water.

In cases where a fair number of prints are required, and where also time permits, it is perhaps more satisfactory to wash and then the negative before printing from it. For this purpose the well-known method of drying in spirit for a few minutes and then putting on a current of air to dry may be adopted, and the same process can, of course, be applied to the prints themselves.

MAX FRANK

\* As given by the author the above formula is meaningless, since it is direct dissolve certain specific weights of the constituents in a number of "parts" of water. However, the above bath may be made up by dissolving the quantities of chemicals given in 500 cc.s., or 20 oz., according to the system of weights and measures adopted.—Eds. "B.J."

## ARE SILVER RESIDUES WORTH SAVING?

SINCE I first set the residues ball fairly rolling, by an exhaustive article on the subject which I contributed to these pages nearly forty years ago, the processes of commercial photography have undergone such a radical change that the above question is nowadays frequently put, and, in very many cases, treated as though a negative answer were the only one possible, and this is rather remarkable, for at the time I speak of profits were comparatively large, and many professional photographers did not think it "worth while to bother about residues." Yet, at the present time, to show a balance on the right side is no slight difficulty in a very large number of what were once highly profitable businesses. In the early seventies the sheet anchor, both of the portraitist and the view producer, was albumenised paper, while P.O.P. and collodion

paper hold the field of silver printing at the present day. I propose to show figures of actual working to enable anyone to form his own judgment on the question. First, let me draw attention to the fact that my knowledge of the working of a large number of studios which I may at once say is unusually extensive—I have had correspondence from all parts of the kingdom, apart from personal interviews—enables me to assert that in the large majority of studios during the whole of this long period of time the waste of uncollected silver has been absolutely appalling. One of the largest users in London, if not absolutely the largest, told me himself he never worked up his old hypo baths, he simply "sent them down the sink," and his annual purchases of albumenised paper were counted by hundreds, not scores, of pounds. In most stu-

print washings have been collected in more or less perfunctory manner, the principal paying little attention. I know one firm in Africa, doing a most extensive business in developing and printing, who, the manager informed me, permit the operators to keep residues as a kind of perquisite—an establishment where a bath containing two or three tubes of gold is at once thrown down the sink if it does not seem to be working right—when it would be no trouble worth speaking to obtain the whole of gold back again.

To get to actual figures, I will give the results of some weighing of residues actually obtained in the daily working of P.O.P., first dealing with the washings from the prints before they are printed. Here let me interject the remark that the prevailing opinion that in the use of P.O.P. the milkiness in the washings (if hard water is used) is largely due to baryta washed out of paper is entirely erroneous. I have not once, in many trials with different makes of paper, been able to discover any baryta, after washing unduly prolonged.

carefully collecting all the wash waters from nearly a quire of paper printed, and throwing down with hydrochloric acid (commonly called "milk of lime") is quite good enough for the work-room) which is the deposit to settle more quickly than does chloride of silver. I found, using one make of paper only, each sheet to contain 3.45 grains of chloride of silver, equivalent to 2.599 of metal (2.6 grains) or 62.4 grains of silver for each quire of paper. In words, if the washing waters are most carefully saved the value of the silver collected from a quire of paper, or 384 cabinet prints, taking silver at 2s. 6d. an ounce—a value rarely lost of late—would be 49d.

Now, to spent "fixing solution" used for gold-toned prints, and throwing the silver down as sulphide, 7.76 grains per sheet was obtained, equivalent to 6.98 grains of metal, or 167.52 grains per quire, worth about 10½d., still taking silver at 2s. 6d. per ounce. The total product from the residues from a quire of P.O.P. prints is 1s. 3d., which, if we reckon the paper bought in quantity at 10s. per quire, comes out at 12½ per cent. on the bill for

this is not all. Used-up toning solutions are thrown into the vat, at least have always been at my studios, and this with comes into the hypo from the toned prints very materially increases the value of the metal obtained when reducing the silver. When the residues are sent to the refiner he allows a price for the metal so obtained because of the gold it contains. I have received cash at the rate of 3s. 9d. per ounce for metal obtained from mixed chlorides and sulphides.

It has to be considered the question as to the value obtainable from print cuttings and spoiled prints. The proportion of weight of precious metal to that of the paper being so very small, no experiments such as those detailed above were feasible; but, being the most trustworthy method of arriving at practical results, I collected a batch of this kind, and, first reducing it to ashes, to avoid heavy carriages and expense of reducing (the refiner's charges being so much per pound weight of waste entrusted to him), I sent the ashes on to be reduced. The result was most interesting—I was not prepared for it, and the refiners' note runs thus:—

1b. 1 oz. paper cuttings (ash) producing:—

oz.	oz.	dwt.	grs.
70 F.G.....	—	1	12 at 2s. 8d. per oz.
F.S. ....	11	16	—

1s. 10d.,

silver at the time being worth 24½d. per oz., so that all I need for over two pounds' weight of waste prints and cuttings is less than 2s., which was more than swamped by the refiners' price for reducing.

Conclusion.—Do not collect silvered paper for burning, but throw it into the waste fixing solution, and then throw down the silver as sulphide.

I think I have provided quite sufficient data to show whether it is worth while to collect residues—a minimum saving of 10½ per cent. off the paper bill (possibly over 15 per cent.) is conclusive. The best method of going about the work it would prolong the article too much to describe it; but if it prove to be of sufficient interest I may deal with it on a future occasion.

G. WATMOUGH WEBSTER.

## THE AMMONIUM PERSULPHATE REDUCER.

ALTHOUGH this reducer is by no means of recent introduction it still continues to attract considerable attention, both from the practical and theoretical points of view, particularly on the Continent. Herr Braun, in "Photographische Kunst," deals more particularly with the practical side. He points out that the first point to decide is whether the salt is fit to use, which can be easily ascertained by holding the vessel in which it is dissolved to the ear, when, if in good condition, slight detonations will be heard. The solution acts differently according to the plate, the developer, and the time that has elapsed since the former was fixed.

It is essential that the plate should be free from hypo. The latter may be eliminated with potassium permanganate, but the author prefers to render some of the persulphate solution alkaline with ammonia and flood the negative with this, pouring it off, and then acidulating the solution with a little sulphuric acid. The addition of the acid should be made as quickly as possible and the solution always tested with litmus paper for acidity; about 7-10 drops of ammonia or pure sulphuric to every 100 ccs. is about the quantity. It is not advisable to rock the dish until the solution begins to get milky, or a white deposit appears on the negative. The plate should be examined about every ten seconds, and, when the reduction is sufficient, should be placed in a 10 per cent. solution of sodium sulphite for five minutes and then well washed.

If the developer was not pure or the fixing bath contaminated with silver bromide, the reduced negative may be brown, and not black, and the dense parts may not be reduced more than the shadows. Black spots are due to traces of hypo.

Herr Pinnow deals with the persulphate reducer in the "Zeitschrift für Wissenschaftliche Photographie" rather from the theoretical point of view, and comes to the following conclusions:—

1. A small quantity of silver sulphate is formed by the action of persulphate on metallic silver, according to the equation

The silver salt and the persulphate react and form silver oxide—

The three latter products give fresh silver sulphate, and the action begins again; only the process must take place in half the time, since the quantity of silver salt is doubled by the reaction. The silver salt acts catalytically.

2. In ammonium persulphate there are small quantities of Caro's acid, as can be proved by adding to a very dilute solution of potassium iodide and starch, a few drops of sulphuric acid and some thiosulphate. If 2 per cent. of decinormal silver nitrate solution be added to the persulphate Caro's acid cannot be detected. Hydrogen peroxide is not formed, but ozone. The evolution of ozone or ozonized oxygen from Caro's acid is considerably hastened by the addition of a silver salt. If, therefore, a little silver salt is formed from the metallic silver and persulphate it can catalyse Caro's acid; the ozone forms silver peroxide with the metallic silver. The formation of Caro's acid is accelerated by the increase in acidity, and its decomposition accelerated by the increase in silver salt. Most likely the two processes run concurrently. That this is probably the case is proved by the formation of small gas bubbles on the film when it has been previously treated with a silver salt.

3. According to R. Kempf persulphuric acid oxidises ammonia to nitric acid under the influence of silver salts, and silver peroxide, the actual oxidising agent, is first formed.

Persulphuric acid itself does not act on ammonia. Nitric acid may thus be first formed by the action of the silver salt and then clear up the plate.

A considerable quantity of silver goes into solution when reducing with persulphate, and this is generally the cause of the numerous spots. As a rule, the average amateur has not distilled water at his disposal. The dissolved silver is precipitated by the chlorides of spring or tap water as silver chloride, and where a cloud of silver chloride forms, the reduction is accelerated and a spot is formed. For reducing with persulphate distilled water is absolutely essential.

the drawings, figs. 1 and 2 illustrate, diagrammatically and plan, means whereby the films or screens may be produced, and 3 illustrates a contact printing frame for use with a granulated or screen. In figs. 1 and 2, *a* represents a camera, *b* is the sensitive plate or film, and *d* is a suitable easel. In 1, *e* is a Levy or other similar screen, and *f* is a textured surface, which are illuminated in any suitable manner by transmitted light, which may be direct or reflected light, as will be understood. The positions of the screen *e* and textured surface may be reversed, and in some cases the textured surface (or) screen *e* may be arranged near to the plate *c*, as indicated by the dotted lines at *e*<sup>1</sup>, instead of upon the easel. In fig. 2, the textured surface or material *f* is arranged on the easel and illuminated from one side by natural or artificial light (an electric lamp being indicated at *g*), and the screen *e* is arranged near to the plate *c*. In all cases illustrated by figs. 1 and 2, the result pro-

Fig. 2.

duced on the plate *c* (or a positive taken therefrom) will be a screen combining impressions of the process screen with the textured surface. In producing a textured surface screen by the means shown in figs. 1 and 2 for use with negatives (or positives reversed) which are to be taken through a Levy or similar screen, screen *e* is not employed, the photograph being made of the textured surface *f* alone.

Fig. 3 is a sectional view of a printing appliance suitable for contact printing, in which provision is made for the removal of the textured screen (and in some cases, the substitution of another) between the sensitive surface and the negative, while maintaining the accurate register. *h* is a frame, *i* is the negative, *k* is film or screen, *l* is the sensitive surface (for example, printing paper), *m* is a clamping device composed of two parts hinged together at *r* for securing one end of the paper *l* firmly with regard to the frame and the negative, the two parts being preferably dovetailed and tongued, as shown at *s*, and *n n* represents the removable back which clamps the sensitive paper in close contact with

Fig. 3.

screen or negative. The clamp *m*, which exactly fits a suitable opening formed at the end of the frame *h*, may be arranged, as shown, to automatically adjust itself and the paper to the negative when the screen has been withdrawn; for this purpose the clamp is adapted to grip the end of the paper, and a projecting part, *m*<sup>1</sup>, is adapted to rest upon the edge of the screen, so that when the screen is removed the part *m*<sup>1</sup> is forced by the resilience of the bridge *o* and screw *p* on to the negative without allowing the paper *l* to alter its position with regard to the negative, thereby maintaining the accurate register.

In some cases, a piece of plain transparent material may be substituted for the withdrawn screen to ensure accuracy of register and obviate the necessity for an adjustable clamping device such as shown.

It will be understood that for printing by projected light, the screen would be held in a suitable frame which would permit of

the withdrawal of the screen, or the substitution of another, without injuring the accurate register of the image on the sensitive surface. Ernest Howard Farmer, 3, Coleraine House, Nassau Street, Mortimer Street, London, W.

**METALLIZED REFLECTING BANDS.**—No. 25,165, 1907. The claim is for an opaque cinematographic band composed of Bristol board, paper, or other analogous support, which, on the face bearing the images, is provided with a brilliant metallic coating, so that the luminous rays which it reflects produce on a screen a very luminous projection of the images. Edouard Dupuis, 36, Avenue des Minimes, Vincennes, France.

**GLASS-PLATE CINEMATOPHONES.**—No. 4,040, 1908. In an addition to Patent No. 3,987, 1908, it is wished to indicate that the special apparatus may be used for taking animated pictures directly whenever the size of the projection does not exceed the limit at which the grain of the plate would be visible upon the screen. Jean Leon Muller, 8, Avenue Berthet Sannois (Seine et Oise), and Jules Rousset, 27, Cours Marigny, Vincennes (Seine).

The following complete specification, etc., is open to public inspection before acceptance under the Patents Act, 1901:—

**TELEGRAPHIC TRANSMISSION.**—No. 16,272. Apparatus for reproducing at a distance pictures or designs. Belin.

## New Trade Names.

**PRAKMA.**—No. 304,360. Chemical substances used in manufactures, photography or philosophical research and anti-corrosives. Praktische Maschinen Gesellschaft mit Beschränkter Haftung, 77 and 78, Ritterstrasse, Berlin, Germany, manufacturers. June 30, 1908.

**RECORDOL.**—No. 304,363. Chemical substances used in manufactures, photography or philosophical research and anti-corrosives. Praktische Maschinen Gesellschaft mit Beschränkter Haftung, 77 and 78, Ritterstrasse, Berlin, Germany, manufacturers. June 30, 1908.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Figure Studies in Holland.

Personally (writes Mr. James A. Sinclair, in the "A.P. and P.N." for August 18) I prefer a camera with an accurate small finder, in which the picture may be perfectly composed, and with a shutter working, say, from 1 second to 1-100th second. If taking subjects with figures, I estimate the distance at which I want to take an advancing figure, put the pointer on the focussing scale at that distance, and hold the camera by my side in waiting. Supposing a suitable figure or group advances, I quickly bring the camera to position just before they reach the desired spot, see that level and finder are correct, and press the trigger.

As a rule, this can be done so quickly that the objects are quite unconscious that they have been taken. If heterodox about cameras, I am equally so regarding plates. No plate is fast enough for me, and my allegiance is always at the service of the maker who can give speed without fog. Slow plates tend to hard results; orthochromatic ones seem to sacrifice breadth, and, apart from this, are usually slower. I am no convert to orthochromatics. Colour-correct plates may give results which are scientifically correct, but skies taken with them seem to lose the idea of luminosity. To-day I favour the Ilford Monarch, and always use them backed. They give detail with minimum exposures, and density can be secured with sufficient development. When an equally good plate of double or even ten times the speed is made, then I shall use it.

### Photographs of Golfers.

It is all a question of hand and eye (George W. Belknap is quoted in the "Photo-Miniature" as saying) as in any other game, but two things are most necessary—a camera with a full-sized finder and a

focal-plane shutter, and a knowledge of the golfing swing. In other words, the camera artist must be a golfer. The fact that when the button is pressed the full-sized reflector springs up and releases the focal-plane shutter, really helps the operator to time more perfectly. There is only a fractional part of a second between the pressing of the button and the releasing of the shutter; the reflector has to spring up to get out of the way and release the shutter. Hence I soon found I had to allow for this and press the button just before I wanted to. This short space of time, in my opinion, just fits in with the golfing swing, and also compensates for the difference there would be between the eye seeing and the hand pressing. I therefore watched the wrists working and not the club-head, and I soon found that practice gave me the necessary knowledge when to press. I seemed to know when one had been mis-timed, and immediately took another of the same stroke. When taking a great number in one day I seemed to get set, as one does at cricket, and could then be certain of my efforts being absolutely timed. The top of the swing, of course, requires more timing than the finish, but the most ticklish is to catch the ball at, or immediately after, impact in the drive, so as to show the ball and driver on the plate. Of course, in such a case there is considerable movement of the club and the ball, but this gives a better idea of the pace at which they were travelling, especially when it is remembered at what speed the shutter was working, 1-1000th to 1-1250th of a second.

## New Books.

**PHOTOGRAPHING OUTDOOR SPORTS.**—No. 91 of the "Photo-Miniature" is very opportunely devoted to this branch of photography, and collects within a small space the experience and advice of a number of expert workers in the different branches of press and sport photography. It is only natural that the most useful counsel which can be given the photographer of such subjects does not concern the actual photographic practice, but takes the form of hints from experts in the various sports as to the most essential features of the game which should appear in the photograph. In other words, the successful photographer of sporting events of any kind must also be a sportsman; if not a practised player of the game, at any rate, so frequent a spectator of it that he can instantly appreciate good and bad play, and is prepared to bring his camera into action at the right moment. The "Photo-Miniature" rightly treats its subject from this standpoint and may therefore be recommended as a helpful text-book. (Dawbarn and Ward, Ltd., 6d. net.)

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### SATURDAY, AUGUST 22.

North Middlesex Photographic Society. Outing to Loughton and Chigwell.  
South Suburban Photographic Society. Excursion to Godalming. A. K. Dannatt.  
Leeds Camera Club. Excursion to Scarborough.  
Birmingham Photographic Society. Excursion to Cannock Chase.

#### MONDAY, AUGUST 24.

Southampton Camera Club. "Portraiture." W. R. Kay.

#### WEDNESDAY, AUGUST 26.

Rugby Photographic Society. Excursion to Lutterworth. G. A. Towers.  
Leeds Camera Club. Lectures by Members. Arranged by John Jax.  
North Middlesex Photographic Society. Short Papers by Mr. Hare and Mr. Rollings.  
Birmingham Photographic Society. Evening Ramble to the Lickey.

MESSRS. T. NAYLOR AND CO., LTD., advise us that they have removed from 24, Denmark Street, Charing Cross Road, to more commodious premises, at No. 5 in the same street, opposite the old address.

## Dew Apparatus, &c.

The "Wellington" Exposure Disc. Sold by Wellington and Ward, Elstree, Herts.

In the form of a cloth-covered folder measuring 4in. by 6in., Messrs. Wellington and Ward have provided users of their "Wellington" exposure calculator, which, without arithmetical computation whatever, allows of the exposures of most diverse kinds being quickly ascertained. The basis of the calculator is the table of light variations for different times of day and year which is employed in conjunction with a disc slide-rule. This latter thus requires only two adjustments to the exposure for any stop from  $f/5.6$  to  $f/64$ , and for a range

subjects from clouds (sea and sky) to dark interiors. The calculator makes provision for the use of plates of a wide range of sensitivities, adopting the H. and D. markings, in which connection it may be interesting to quote the numbers taken as the average by Messrs. Wellington for their several brands: "Xtra Speedy," 350 to 400; "Speedy," 250 to 275; "Iso-Speedy," 225 to 250; "Landscape," 150; "Ortho-Process," 80 to 100; "Lantern," 10.

The exposure disc is issued at the nominal price of 9d., and, as can say from our own use of it, may be recommended as a useful and convenient guide to exposure.

## Commercial & Legal Intelligence.

OFFICIAL NOTICE is given of a first and final dividend of 5s. 6d. to be paid to the creditors of Alfred Ernest Priest, photographer, of 21A, Prince of Wales Road, Norwich, and residing at 51, Sprowston Road, Norwich.

UNDER an agreement recently entered into, Mrs. Chas. Grove (Miss A. West) ceases to be a general partner, and becomes a limited partner in the firm of A. West and Partners, carrying on business as photographic printers, etc., at 91-98, York Street, Westminster, S.W.

A NOTTINGHAM BANKRUPTCY.—At a meeting of the creditors of a bookbinder named Robert William Clark, held at the office of the Official Receiver last week, it transpired that in September, 1907, the bankrupt commenced business as a photographer in Arkwright Street, Nottingham, taking premises there on a lease for five years at a rental of £50 per annum, and fitting them up at an expense of about £200. He stated that his business was not a paying concern, and that about February, 1907, he disposed of this concern to a wife for £80. The business is still being carried on by the bank

but apparently no alteration has been made in the trading nor was any notification given to creditors or others of any of ownership. The bankrupt stated that his wife's father had all liabilities of the business. This matter, said the Official Receiver, required further investigation.

## NEW COMPANIES.

**RIESE-GREENE PATENTS, LIMITED.**—Capital, £2,400 in £1 shares. Require the right and interest of A. Ramsay in certain patents, claims and rights comprised in an indenture between G. W. Ramsay, W. Friese-Greene, and C. J. Morris, and to carry on the business of manufacturers and exhibitors of, and dealers in, cinematographs, bioscopes, and other apparatus, etc. Private company. Number of directors is not to be less than two nor more than three. The first are:—A. Ramsay, W. Friese-Greene, and A. S. F. Ramsay. Qualification, £10. Remuneration, £25 each per annum. Registered office: 64, Victoria Street, Westminster.

## News and Notes.

**PHOTOGRAPHER'S SILVER WEDDING.**—Mr. G. H. Stanford, photographer, of Boscombe, and Mrs. Stanford, celebrated their silver wedding recently and were the recipients of numerous congratulations.

**"RAJAR" CAMERA** offered monthly by Messrs. Rajar, Ltd., Weymouth, Dorset, for the best print on "Rajar" P.O.P., has been sent to Mr. G. Elvin, The Square, Fakenham, Norfolk, his print being judged the best during July.

**PHOTOGRAPHY AND THE WATER RATE.**—At the Redruth Urban Sanitary Council last week considerable discussion ensued upon the subject of a letter from Messrs. Opie and Son, photographers, in which the Council had decided to place a water meter. The Council stated that they objected to being singled out, and considered themselves unjustly treated. Several councillors pointed out that the Council's desire was to make a test, and that Messrs. Opie would not be charged according to the amount recorded on the meter.

Should it be discovered that more water was running through the meter than was paid for, each photographer would be supplied with water.

**C. PHOTOGRAPHIC RECORD.**—That the London County Council extensive use of photography in its various municipal undertakings is a well known fact, and the following account of the work of the special photographic department, which we take from the "Illustrated London News," may be recommended to the perusal of professional photographers for its suggestions as to the work which may be done for smaller public bodies in their own neighbourhood which should keep a photographer regularly employed.

Perhaps the most interesting among the collection are those which record incidents at ceremonial events in connection with the Council's work, in which members of the Royal Family and other distinguished persons have been the central figures. For example, the collection includes some admirable photographs of scenes at the opening of Millwall Dwellings by their Royal Highnesses the King and Queen, the launching of the Thames steamboats by his Royal Highness the Prince of Wales, and the opening of the Horniman Museum by the Duke of Devon.

Another specially interesting branch of the collection includes photographs of historic London houses which have been demolished in recent years. Whenever an old London house, which is historically or architecturally interesting, is pulled down in connection with other improvements, the Council takes care to have photographs taken of the exterior and of the more interesting features of the interior.

This rule applies not merely to houses pulled down by the Council itself, but also, as far as possible, to houses demolished by private owners and by private persons. Of quite exceptional interest is a collection of photographs, nearly one hundred in number, taken by the Council in connection with the Kingsway and Aldwych im-

provement, which illustrate in vivid fashion the contrast between the squalid, overcrowded streets that once covered this area, and the noble thoroughfares that have now taken their place.

"Other photographs in the collection show scenes in the Council's various parks and open spaces, London schools with children at work and at play, the interiors and exteriors of fire stations, and other interesting phases of the Council's vast administrative activities.

"Enough has been said to show that to coming generations of Londoners the collection will be of incalculable interest, while to future historians and topographers its value will be inestimable."

**"FREE ENLARGEMENT" FRAUDS.**—In reference to this now well-known form of fraud, a correspondent writes to the "Edinburgh Evening News" recently as follows:—"Some time ago I was asked to give quotations for enlargements measuring 20 inches by 16, mounted on stout cardboard. On interviewing the man I was told that unless I could put them in somewhere about 7d. each I need go no further in the matter. Needless to say, I went no further. He even hinted of a Berlin firm having made a lower offer. The reason he gave for not closing with the magnanimous offer was that he would rather encourage his own countrymen. Perhaps he was a Tariff Reformer himself, wishing to have something for nothing out of the British working man. Framing costs but a few shillings, and even with the assistance of a cheap German moulding, the enlargement, as the cost price shows, is plainly mere rubbish. The great blessing, however, is that it will soon vanish, the purchaser having the satisfaction of possessing that for which alone he has paid or overpaid—viz., the frame."

**TO REPLACE CELLULOID.**—According to an American Consular report from Chemnitz, a German chemist has lately perfected a process which brings into competition with celluloid a new composition possessing similar plastic and elastic properties, but free from the easy and somewhat dangerous combustibility common to celluloid articles. Such hollow objects as balls, dolls' heads, and the like are now as easily prepared as from celluloid. The latest application, that with regard to cinematograph films, is among the most important. Its manifest superiority over celluloid for this purpose results from its non-combustibility. A film exposed for ten minutes to the concentrated light of an arc lamp does not exhibit the slightest alteration.

**THE THORNTON-PICKARD £100 PRIZE COMPETITION, 1908,** is now announced, and copies of the entry form and rules will be sent post free to all applicants. The competition is organised on the same lines as in previous years, but there are several new classes and also new rules, which will enable photographers of all classes and grades to compete, and those who possess any kind of apparatus made by the Thornton-Pickard Company would do well to write for a prospectus without delay, whilst those who are uncertain as to what make of camera to purchase should write for the firm's catalogue. The competition closes on October 1, on or before which date all prints must reach the company's offices at Altrincham, Cheshire.

**DEATH OF A PHOTOGRAPHIC WRITER.**—We learn from "Der Photograph" of the death, on August 7 last, of Herr Fritz Loescher, a well-known writer on photographic topics, in Germany. The late Herr Loescher was a student of H. W. Vogel and of Dr. Aarland. Perhaps his best known work was "Leitfaden der Landschafts Photographie." He had for several years past contributed the article on "Pictorial Photography in Germany" to "Photograms of the Year."

**THE LATE MR. W. C. HUGHES.**—The death took place on the 7th inst., after a long illness, of Mr. William Charles Hughes, of "Belvedere," Woodside Park, N., at the age of sixty-four. The deceased gentleman formerly carried on business at "Brewster House," Mortimer Road, Kingsland, N., as a specialist in optical projection, was the inventor of the "Pamphengos" lantern, and was well known throughout the lantern trade. Mr. Hughes had retired from business some four years ago, but the prestige of the firm in lantern matters has been maintained by his successor.

**ATTRACTIVE EXCURSIONS FROM PADDINGTON.**—An interesting programme of excursions from Paddington Station is announced by the Great Western Railway for the near future. On Saturday, August 29, a new circular day trip through the Garden of England, embracing Stratford-on-Avon (Shakespeare's birth-place), Broadway (England's most beautiful village), and Cheltenham (the Garden Town), will be run from Paddington at 8.20 a.m., and will

enable passengers to spend 3½ hours in Stratford-on-Avon, 2 hours in Broadway, and 2½ hours in Cheltenham, arriving at Paddington at 10.15 p.m. The return fare will be 7s.

Another circular day trip is also announced to the Wye Valley on Monday, August 31, leaving Paddington at 8.20 a.m., and giving passengers the opportunity of dividing the day in various ways at Chepstow, Tintern, Monmouth, Symonds Yat, and Ross. The return fare will be 7s. In addition to these, there will be many other attractive trips from Paddington.

**ROTHERHAM PHOTOGRAPHIC SOCIETY.**—This society will hold its 19th annual exhibition from October 14 to 17, 1908. There are, as usual, open classes, including one for "Photographs in colours," in which, of course, Autochromes are eligible. Applications should be addressed to the Hon. Sec., Mr. H. C. Hemmingway, Tooker Road, Rotherham.

## Correspondence.

\*.\* *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

\*.\* *We do not undertake responsibility for the opinions expressed by our correspondents.*

### TANK DEVELOPMENT.

To the Editors.

Gentlemen,—I have read with much interest the various letters and notes in the "Journal" re tank development and its defects. Last year, here, I experimented a good deal with it and got in every instance perfect results, and such confidence had I in it that on taking a three months' photographic trip to India last winter, I took a tank developing outfit for both ¼ and ½ plates, as it is always interesting to develop a little en route. My subjects were chiefly figures, and in many cases in or near water, and, of course, in all cases the clear, hard blue sky that is always present in India in winter.

The negatives in a great number of cases showed the serious streak effects and sky mottlings that many of your correspondents speak of, but for some time I did not suspect the tank, but put it down to atmospheric and like conditions. However, on returning to Kyoto and starting the development of the bulk of the plates I clearly traced it to the tank and reverted to tray development and got perfect results. Though no one can doubt the great convenience and speed of tank development, yet, unless some device is found to keep the tank in motion all the time, it is impossible otherwise to get negatives without these streaky defects. I send some negatives to show the extreme form one gets with figures taken against the light and in water and with clear blue skies.—Yours faithfully,

THOMAS B. BLOW.

Kyoto, Japan, June 30, 1908.

[The negatives show the curious dark streaks running from shadow portions of the negatives. We must say, however, that in a lengthy experience of tank development, we have never got such markings when taking the precaution to rock the tank every now and then. Perfectly quiescent development is evidently a necessary condition of their appearance.—Eds., "B.J."]

### DEFERRED STAMPING OF AGREEMENTS.

To the Editors.

Gentlemen,—Your reply to Y. Z., page 578, last issue, states that "If the agreement is not stamped it is of no value, and your late employee can start business just where he likes and you cannot prevent him." May I add that under certain circumstances the Inland Revenue will allow a document to be stamped upon payment of a small fine, varying from 5s. to £10.

The plan is to write a letter asking them the costs or fine, enclose the agreement, using a foolscap envelope and large size paper, foolscap by preference, and sending it either to the Commissioners, I.R. stamping department, Somerset House, London, W.C.—the postage need not be prepaid—or else the agreement and letter can be handed to the nearest post office, which will transmit it, and

will also be entitled to take the costs fee, if Y. Z. chooses the sum demanded.

Before doing so, Y. Z. should consult a solicitor to see if the agreement is legally expressed, as the writer once lost a case, owing to the word "penalty" being used, instead of "damages."

Another tricky clause is the radius embraced in which was prohibited from opening; for instance, it has been laid down that three miles from a London studio is an excessive distance whilst in the country, on a sparsely populated part, 10 miles is not considered an excessive distance. What is known as "the radius of trade" plays an important point.

The following is a good example: "That the said Y. Z. shall open in the photographic portrait business, either as principal or agent, within a radius of two miles from the market cross of the City of Worcester, neither in the townships of Little Malvern."

This any County Court judge would allow, and give judgment in favour of the plaintiff.

It is also better to have a sum stated as "agreed damages" if he has no idea of so opening when you engage him, it does not signify if it is £5 or £500, as he would never be called upon to pay the damages.

It is also well to limit the time, say within the next 7, 14, or 30 days; this influences the judge also. ARCHER CROFT.

## Answers to Correspondents.

\*.\* *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C."* Inattention to this ensures delay.

\*.\* *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

\*.\* *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & COMPANY, 24, Wellington Street, Strand, London, W.C.*

\*.\* *For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street Strand, London, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, for two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

A. W. Debenham, 72, High Street, Cowes, Isle-of-Wight. Two Photographs of the King, Prince of Wales, and Prince Edward of Wales on the "Osprey" and "Albert."

**HARD CASH.**—We know nothing as to the actual value of the photograph. We should not be disposed to value it too highly. We think your own instinct should be your best guide. If it is not, better to let it go than to keep it up the idea of such work.

**QUANTUM.**—The cost of a provisional protection is £1. A provisional agent's charge will be £2 or £3 if the specification does not cover a great deal of work. Apply to Messrs. Rayner and Co., Chancery Lane, E.C.

**SELLING TONING BATHS.**—Can you kindly advise on the proper matter? In addition to my work as a photographer I am venturing up a fair little connection in supplying plates, papers, and sensitizers to amateurs. Sometimes I am asked to supply a toning and fixing bath or a developer of my own making up, and my question is Can I make up and sell a combined toning and fixing bath developer and not render myself liable to prosecution, if I send my customers to a chemist for such goods? I should be glad of your reply, as I only want to do what is right.—To the Editors.

Certainly, there is no objection to your selling such preparations provided they do not contain scheduled poisons. Of the only ones which are likely to occur in any photographic preparation are (1) cyanide or (2) mercury compounds. Only a quantity

pharmacist may sell such compounds, or mixtures containing them, at a retail way.

**FERO-TYPE CANNON CAMERA.**—Can you give me the address of a firm supplying a ferrotype camera in the shape of a cannon, the length of which is about 16in. or 17in. long, and takes pictures about the size of a shilling? I am given to understand the camera has a developing and fixing tank combined, and finishes the photo in about twenty seconds.—N. HART.

The cameras are sold by an American, who is at present located at 2, York Street, Covent Garden, London, W.C. Apparently he is an agent of the Chicago Ferrotype Company.

**FERO-PRUSSIAN COPY.**—It is desired to reproduce a long roll of ferro-prussiate (blue print) same scale. Negatives if taken would be expensive. Can the original be used as a negative? If so, what process would give the best results? It will not reproduce on to other pieces of prussiate, or but faintly on to sepia.—PRINTER.

There is no satisfactory method of taking a contact copy from ferro-prussiate print. We can only suggest that a tracing be made by hand or the original obtained, and a copy taken on sepia paper.

**DEVELOPER.**—(1) I want a formula for the development of ferro negatives (children), pyro-soda preserved with nitric acid and without bromide. I wish to take one ounce of each working solution, to be used for one  $\frac{1}{2}$ -plate only, which, when developed in it, will give just the requisite density for P.O.P. by artificial light printing. Will you fill in correct quantities? Working solution: No. 1. Pyro 1 oz., Nitric Acid —, Water —. No. 2. Soda Carb. —. Negative to be cleaned with citric and alum bath. (2) What is the cause, when using standard formula, of chalky high-lights?—PRINTER.

Nitric acid, in our experience, is not a good preservative of ferro if the latter is kept in such weak solution, as it must be, as to comply with your conditions. A suitable developer for ferro-prints contains about 2 grains of pyro per ounce, that is, say, your stock solution, which is to be mixed with an equal volume of the soda solution, should contain 4 grains per ounce, which means that the ounce of pyro must be dissolved in 110 ozs. of water. You can try the effect of preserving the pyro with 30 or 30 drops of nitric acid, but do not expect the solution to keep long. The No. 2 solution should be: Soda carbonate, 2 ozs.; soda sulphite, 2 ozs.; potass. bromide, 20 grs.; water, 20 ozs. We think you are needlessly worrying yourself as to formulae. Why not use that of the makers? As to density, you must develop for the necessary time. (2) Under-exposure.

**FEEL SUPPLY.**—I enclose the postcard which is full of white spots. I feel certain the fault lies with the water meter, as I have tried another tap without the meter (same connection with main pipe) and postcards were entirely free from spots. Could I compel the Corporation to remove it, or threaten them for loss of material and time, etc.? I have tried thick wool filter, but to no purpose.—W. WARRICK.

We doubt if you can enforce the removal of the meter, but we should be surprised if the Corporation do not comply with your request to help you in the matter. We suggest you approach them.

**PRINTING PAPER.**—I saw some time ago that one of the leading professionals (I believe Hoppe or Furley Lewis) used a very thin paper, which was only obtainable in Germany. I should like to be able to get a good plain sensitised silver paper, but in any case the paper I should like should be quite thin, almost like rice paper. Can you help me with any address?—S. E.

Try Trapp and Münch, Friedberg, Hessen, Germany. We believe they are the makers of the paper used by Mr. Hoppe.

**STAMPS.**—1. Please tell me the makers of the "Primus Solito" camera? 2. Where can I purchase matting varnish? 3. Where can I get coloured oxides to be used when stamping my name on mounts?—VARIOUS.

1. Messrs. W. Butcher and Sons, Camera House, St. Bride Street, E.C. 2. From most dealers or from a maker such as the Vanguard Co., Maidenhead. 3. Try W. Harrison and Co., 6, Mincing Lane, E.C., or better consult a good local decorator, who we think could procure for you in the trade.

**PORTRAIT TO ORDER.**—Will you kindly advise me through the medium of the JOURNAL what steps I can take in the following

matter? I am a professional photographer, was requested to do a cabinet photo, enlarge same to 20 x 16, colour, and frame complete, for which my charge was 25s. Upon taking the picture to the customer the lady refused to take it, giving me no reason for her refusal other than she "did not like it"; and would not listen to my request that my work should be subjected to the opinion of an expert, remarking that the decision of fifty-five experts would not make her like it. I, however, left the picture in her possession. Trusting you will see your way clear to give me the advice I need.—CONSTANT READER.

You can sue her for the money in the County Court, and presuming that it is a reasonably good likeness of the lady, as good as could be expected from the original, you will probably obtain judgment. The fact that the portrait is retained is in your favour.

**MARKINGS ON PRINT.**—Would you kindly say what you think is the cause of the marks on this photograph? It was returned to me from a lady who has had it a few weeks with a not very complimentary letter. My opinion is that it has been caused by some insect.—B. P.

Your surmise is, we think, quite correct. We have seen similar markings on prints that were with little doubt, caused by insects. Blackbeetles and the like are very fond of gelatine, and we have known them attack carbon tissue. Ants, too, would probably work mischief.

**LENS FOR STUDIO.**—I want to buy a lens for studio use, and would feel obliged if you would advise me what to get. Whether a portrait lens such as Dallmeyer's 3B., and another one for groups; or would it be better to get a large aperture lens such as Staley's F4.5 Euryplan, or Voigtlander's Heliar, of about 11in. focus, to do for both purposes. I do not want to spend more money than is absolutely necessary, but desire to get good instruments so as to be able to get first-class results.—EXWYZED.

All the lenses named are good instruments. The first, however, is the quickest, as that only requires, with the full opening, half the exposure of the others. The others would be the best for groups. You do not mention the size pictures you desire to take, or the length of studio at your command, so that we cannot say what lens or lenses would be best for you to buy. Anyhow, these named are all good.

**DAMAGED DAGUERRETYPES.**—I have lately had two daguerreotypes in a very tarnished condition given to me to restore. I have restored them the same as I have many dozens of others, viz., with cyanide of potassium and somehow or other the treatment has left the images very faint. Could you inform me if there is any process by which I could intensify, or re-develop, the image thereon with safety, thereby bringing them to their normal condition? Your early reply will greatly oblige me, as the customer is rather anxious to see them, and I wish to improve their appearance before he has them, if possible.—A TWENTY-FIVE YEARS' READER.

There is no way of intensifying, or re-developing, the daguerreotype image when once it has been damaged. Had the cyanide of potassium been carefully employed it would not have weakened the image. Nothing can be done with the pictures now.

**USE OF NAME.**—1. Can you tell me if I can legally use the name of late employer thus:—"10 years with Jones and Co."?—B. W. C.

1. You can use the name of your late employer, provided you make his name less conspicuous than your own, or in such a way as not to lead the public to imagine the business is his, or that he is interested in it. 2. Apply to the Paget Dry Plate Co., Watford.

**LT.-COL. J. E. GUBBINS.**—It has a slight advantage as regards brilliancy of image owing to the lesser number of reflecting surfaces.

**PHOTOGRAPHING TOMBSTONE.**—I have a commission to photograph a tombstone in a cemetery close by here, but I cannot get a picture that the customer will have. The objection he raises to the pictures I have done is that the inscription on the stone does not show distinctly so as to be readable. I may explain that the stone is dark granite, and the lettering is merely cut in, and not gilded or coloured in any way, and therefore there is little distinction between the plain slab and the inscription, and very little shows in the negative. Can you kindly give me a few hints

to how I may get a passable result, as the customer is a good one, and I want to please him if possible.—TOMB.

Without seeing the tomb it is a little difficult to advise you. We should suggest you visit the cemetery at different times of the day, when the sun is shining, and note when it shows up the inscription best. A dodge that is sometimes resorted to in similar circumstances is as follows:—Get some whiting and make it into a thick paste or dough with water. Then, with a putty knife, fill in the letters with the paste, and with a duster clean off any whiting there may be on the stone. You will then have the inscription in white on a dark ground, which will show strongly in the negative. After that has been secured, the whiting can be removed by brushing it out with a stiff brush, or it may be washed out with water.

**SENSITISING ALBUMEN PAPER.**—I have been a printer for four years, and now the business has changed hands, and the purchaser, one of the old school, is going to have all the prints made on albumen paper. He got some ready sensitised and I have got on very well with it, but he says that better prints are to be got on paper sensitised at home, and that I shall have to sensitise it. As I have never done anything of the sort before, I shall be glad if you will be good enough to tell me through the "Journal" how I can lay the paper on the silver bath without causing air bubbles, as this at present gives me a lot of trouble.—AMY A.

The operation is really very simple, and there is more than one way of doing it. One is to hold the sheet by two diagonal corners, forming a curve, to lay one of the others on the solution, and then gently lower the paper first one side and then the other on the solution; of course, avoiding imprisonment of air bells between the paper and the bath. Another is to take the paper, place one edge of it on the solution, and then gradually lower the whole sheet upon it.

**J. A. S.**—If you owe the firm nothing, you can sue it for illegal detention of the negatives and for damages. If, however, you are indebted to them, they have a lien upon them, and can detain them until their account is paid.

**APPRENTICESHIP.**—The young man is quite right; he is not legally bound as an apprentice, he is only a weekly servant, and can, as he says, leave on giving a week's notice. To make an apprenticeship binding, the indentures must be stamped, otherwise they are not binding on either party. By the tone of your letter we gather that, by not having the indenture stamped, you thought you would be able to hold the young fellow, and that he would have no hold upon you. In that you are very much mistaken. Not unnaturally, as he has learnt sufficient of the business to be worth more wages than he is now receiving, he wishes to obtain more.

**S. R. (Wales).**—The spots are apparently caused by particles of iron rust in the water in which the prints are washed before toning. The only way of avoiding them is to filter the water before use. This you can easily do by tying two or three thicknesses of close flannel loosely, as a bag, over the nozzle of the taps. If after the bag has been in use for a few days the flannel is removed, it will probably be found thickly coated on the inside with oxide of iron from the rusty pipes.

**STENCIL PLATES.**—I want to make some stencil plates, using very thin rolled copper. Can you tell me of anything that will eat right through the metal except nitric acid, as the fumes given off by that is so offensive to me? I want to make plates as clean as those cut by hand.—STENCIL.

A strong solution of perchloride of iron will do what you require, and gives off no unpleasant fumes; but we doubt if you will get, by any method of etching, the same clean-cut edges as by the usual way of making stencil plates.

**T. V. GREEN.**—You are quite right in your surmise. If the paper is kept unprotected in the room in which your assistant does the sulphide toning, the discoloration of the paper is fully accounted for. We should have supposed that any practical photographer would have understood that, without asking the question.

**PROF.**—The only way to ascertain if the photograph is copyright or not is by searching the register at Stationers' Hall. The fact that the picture is not marked copyright goes for nothing. It is not necessary that it should be so marked. Both you, as

the photographer, and your customer who commissioned you to do the work, would be liable in the case of an infringement.

**OLD PLATES.**—1. If the negative sent is a fair sample of what the plates yield, they are worthless. There is always considerable risk in buying "job lines," particularly when they are sold at the ridiculously low price you paid.—2. The plates may possibly be made usable by the method given on page 839 of the "Almanac," but we do not think it would be worth the trouble.

**C. A.**—As you have the premises on a repairing lease, you will have to repair the roof of the studio. The fact that the glass was broken by hail-stones makes no difference. As the landlord tells you, he cannot be compelled to do the repairs, or made to bear any portion of the cost of them.

**T. WARDLE.**—For whatever purpose you require it, you will probably find it more economical to purchase the pyroxyline than to attempt to make it in half or one ounce quantities at a time. We should advise you to get Schering's celloidine, which is well suited for photographic purposes. Your dealer, if he does not stock it, will procure it for you. Unlike pyroxyline, it may be sent through the post.

**A. R. WHALES.**—You have no copyright in the meantime, notwithstanding that your predecessor registered it. The fact of your buying his business and the negatives does not transfer the copyright in them to you. To have secured that you should have had the copyright in each one duly assigned to you. As the negatives were sold without assignment, the copyright in them is lost.

**W. W. W.**—The stains are clearly due to imperfect fixing. Either the hypo bath was too weak, or the prints were not allowed a sufficient time in it. Another cause may be that the prints were not kept moving the time they were in the bath, and stuck together, so that the solution did not have free action.

**HUNTS.**—Ferrottype dry plates may be purchased ready for exposure. They may be had from Fallowfield's, Charing Cross Road, W.C.

**OLD PROCESS.**—The negative sent is not a wax paper one, but a calotype. The two processes were quite different. Calotype negatives used to be waxed to facilitate the printing, which leads some to surmise they were produced by the wax paper process. The negative has been returned to you.

**STEREO.**—Four inches apart will not be too much when taking distant subjects, such as distant views. But for subjects in which are near objects in the foreground it will be too much, as then the pictures when viewed in the stereoscope would have too great relief. For very close objects—say portraits—the separation of the lenses should not be more than two and a half or two and quarter inches.

**T. BISCOE.**—The cause of the windows of the factory looking as they do is halation. Had you used backed plates, you would not have got it, or perhaps only to a minor extent.

**CARBON.**—Zinc trays will do very well for developing carbon pictures in; indeed, they are what are generally employed for that purpose. But they will not do for the alum solution, as they act upon the metal, which would, in time, be eaten through. For the alum solution porcelain dishes should be used. For very large sizes, wooden troughs, lined with lead, are what are usually employed.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

exhibition of photographic pictures in colour by the Hofmeister and H. W. Müller will open almost immediately at the house of the "B.J." Royal Exhibition this year is to be open every week evening. "Thames in Colour" is to be the lecture on three evenings of the week. (P. 655.)

A receptionist trained in the studio of Mr. J. C. Strauss, of St. James, has read a paper on her ideals of a receptionist's duties and employer's attitude. (P. 660.)

A special report of the recent Convention of the Photographic Association of Canada is given on page 658. There appears to have been much interest in the meetings, one cause of which is suggested on page 654.

Handy Photographer.—An article from a reader in the North-west serves as a reminder of the way in which a photographer going to Canada may have to shift for himself in the matter of apparatus. (P. 658.)

W. E. Debenham explains the precautions to be taken in the correction of faulty uprights in a negative by copying in the camera. Unless the operation is done under suitable optical conditions the defects introduced may be as much as, or more than, those of the negative. (P. 656.)

John Beeby has revived the suggestion of potassium ferrioxalate in the hydroquinone developer for the production of soft tones or prints. (P. 654.)

R. J. Wallace has published a paper on the effect of temperature at the time of exposure on the sensitiveness of plates. His remarks indicate the cause of discrepancy between the results of various observers. (P. 661.)

William Abney has published a note on the curious desensitization of red light. (P. 654.)

Autochromatic plates and glass-plate cinematographs are among the latest of the week. (P. 666.)

One of the important points to be regarded in the purchase and use of an enlarger, to be used chiefly for amateur work, are the points of the editorial on page 655.

A serious burglary of the premises of Messrs. Newman and Guardia took place during the past week-end. A list of the stolen goods is given on page 670.

## EX CATHEDRA.

### Photographic Pictures in Colours at Wellington Street.

About simultaneously with the opening of the Salon and Royal there will be brought together in the "little gallery" at the house of the "B.J." a remarkable collection of photographic results in the shape of multi-colour landscapes by Messrs. Theodore and Oscar Hofmeister and their friend H. W. Müller, all of Hamburg. The pictorial work of the Hofmeister Brothers has been seen in the past at exhibitions and in reproductions, but since they, with Herr Müller, have turned towards multi-colour, the exhibitions in this country have seen nothing of them, and therefore the present collection will afford an opportunity of noting the remarkable progress made by them on forsaking monochrome for the attractive field of colour.

\* \* \*

### Colour Lectures at the R.P.S. Exhibition.

It is announced that in addition to the customary three lectures a week to be given at the New Gallery during the period of the exhibition, a series of three different lectures will be given weekly with Autochrome illustrations. This very notable addition to the Royal Exhibition is due to the energy of Secretary McIntosh, who, during the present summer, has made an Autochrome tour of the Thames from Lechlade to Shoburyness. "The Thames in Colour" should be a powerful draw to the Royal, particularly as it establishes the opening of the New Gallery for every night of the week.

\* \* \*

### The Southern Exhibitions.

For the seventh consecutive year the Southampton, Hove, and Portsmouth societies combine their forces to continue what has become the most successful series of provincial photographic exhibitions. The dates are somewhat earlier this year, but otherwise all the arrangements are on the lines which have obtained during the combination. The reduced fees, the combined form, and the free carriage arrangements all appeal to the exhibitor who wishes to be saved as much trouble and expense as possible, and in addition there will be a small select Invitation Section by leading workers. Good awards are offered, and all particulars and entry forms may now be obtained from Mr. S. G. Kimber, Oakdene, Highfield, Southampton.

\* \* \*

### A Comment on Trade Censorship of Postcards.

An unfortunate comment on the trade censorship of postcards, to be instituted, as we mentioned last week, by a postcard protection association, reaches us from a correspondent in the shape of a postcard bearing the imprint of a prominent member of this very associa-

tion. Opinions may differ as to what is and is not fit for publication, but the card before us is—well, not one to please persons of refined taste; and though not actually indecent, certainly vulgar. The ancient scriptural maxim to take the beam from the eye before seeking to remove the mote from the optical organ of another appears to have its application in the postcard publishing, as in other trades.

\* \* \*

#### American Conventions.

Judging from reports in the Press and private communications, the present season has seen a distinct drop in the interest taken in the fairly numerous conventions held in various parts of the United States and Canada. Papers which can be regarded as anything more than a few remarks strung together on the spur of the moment have been comparatively rare, and the business-like character and conduct of the meetings have shown signs of falling off. Indifference on the part of the members is necessarily the cause of such a state of things, but for this indifference a cause must likewise be sought in the organisation of the meetings. And one source of dissatisfaction is probably to be found in the predominance of the trade demonstrator and lecturer at the transatlantic convention. In some instances this element enters so largely into a convention as to rank with the official proceedings, and it may even go to the length of making the convention the scene of trade reprisals and rivalry. In these circumstances it is not surprising that photographers should fail to see the advantage of travelling long distances merely for the purpose of being exploited by commercial firms. If these allegations be true, the present condition is much to be regretted, since the American conventions in the past have proved an undoubted stimulus to the weaker members of the photographic profession.

\* \* \*

#### Ferrocyanide in the Developer.

Mr. John Beeby, in the New York house organ, "Down Town Topics," revives a formula of developer which was more often heard of ten or fifteen years ago—that is, hydroquinone used in conjunction with potassium ferrocyanide in addition to the usual alkali and preservative. Although ferrocyanide is not possessed of oxydizing properties, its effect in the developer is found to be similar to that of potassium bichromate. In other words, it softens the scale of gradation and keeps down the density of portions such as the sky and other high-lights, which would easily block up. The formula favoured by Mr. Beeby is:

A. Hydroquinone .....	2½ drachms.
Ferrocyanide of potassium .....	6½ drachms.
Sulphite of Soda .....	9 drachms.
Water .....	35 ounces
B. Caustic soda .....	2 ounces
Water .....	12 ounces

These solutions are mixed in the proportion of about two ounces of A to five to eight drachms of B. The developer is recommended as equally suitable for bromide papers, particularly when printing from harsh negatives. It might be interesting to try whether the ferrocyanide in the developer in any way affected the subsequent sulphide toning of the prints as regards colour.

\* \* \*

#### The Collection of Residues.

Mr. Watmough Webster's article on "Silver Wastes" in our last issue drew attention to the fact that in the majority of studios the collection of residues is neglected, even though the value of the silver residues in the case of

P.O.P. prints alone represents 12½ per cent. on the cost of the paper used. The residues from working negatives were not taken into consideration in the article, but the value of these is probably worthy of attention equally with that of the print silver residues, seeing that two or three negatives may be made, even when only a dozen or so prints are required. Seeing that the process of recovery is very simple and costs next to nothing, it is rather surprising that the residues should be quite neglected. In a large establishment it would be quite easy to arrange special sinks for the reception of silver solutions alone, the wastes leading to a vat; or, if necessary, several vats large enough to hold, say, three days' supply of solutions. Every night a little sulphide be thrown into the vat, and every morning the upper half of the liquid be drawn off through a tap the collection will go on practically in an automatic fashion. No doubt the trouble of collecting solutions and of conveying them to the residue receptacle is the main reason for so many neglecting residues altogether, but this trouble should disappear if proper arrangements are made. We see that Mr. Webster advocates the deposit of used gold toning solutions in the general silver residues. This is no doubt the simplest way when combined baths are used, but there is no particular difficulty in collecting the gold from simple toning baths separately and a receptacle for these can be provided in the workroom itself, as they are smaller in quantity and no objectionable sulphide is used. The gold increases the value of the silver residues, but at the same time the silver depreciates that of the gold on account of the extra trouble required to separate them. Further than this, pure gold residues can easily and very cheaply be worked and converted into chloride by the photographer himself.

\* \* \*

#### The Reversing in the "Photographic Journal," Action of Red Light.

William Abney publishes a communication by himself on the "Destruction of an Image by Visible Rays of Low Refrangibility." He points out that if a plate sensitive only to violet and blue-green, that is, an "ordinary" plate, is fogged slightly with light and then exposed to the spectrum, the fog disappears or is less intense in the red and yellow portions. This fact suggests that the red and yellow rays undo some of the work effected by the violet and blue-green, or, as William puts it, "when the photographer is using such a kind of plate part of the effect due to some components of the white light is being undone by other components." The reversing effect of the red rays has frequently been referred to by Sir William Abney, but other investigators seem to have rather neglected it. It opens rather a big field for experiment, and some interesting results might be arrived at by a careful investigator.

\* \* \*

#### On the Cutting of Plates.

An old trouble that used to worry photographers very much at one time was the issue of plates that were not cut exactly to standard sizes. We have often handled plates that were just too large to fit the dark slides, and occasionally met with plates small enough to fall through the rebates that should have held them in place. We thought that modern methods of cutting plates had relegated such troubles as these to things of the past, but during the last few weeks we have been disagreeably surprised to meet with them again. In these recent instances the plates were not cut square. One end will fit in the rebates, while the other is just too large to go in without very considerable force being applied. When fitting slides in the dark tray it is nothing so annoying as a plate that will not fit, but when carriers take the place of slides the case is even

worse. On gauging up these plates we find that all the plates we have of the brand to which they belong are cut a shade larger than the plates of other brands of the same manufacture. They are all full  $3\frac{1}{4}$  inches wide, while the others are bare  $3\frac{1}{4}$  inches. The defective plates are well over  $3\frac{1}{4}$  inches at one end, nearly  $3\frac{1}{2}$ , the result being that they will just fit some slides with persuasion and will not go into others at all.

### SOME POINTS CONCERNING THE ENLARGING LANTERN.

At this time of the year many photographers are turning their thoughts towards a winter programme of work, and it is not a few will shortly be considering the purchase of appliances for enlarging, some hints on the most important features that the apparatus should possess may not be out of place. There can be no doubt that the lantern is by far the most convenient form of enlarger, and in these days there is no difficulty in obtaining a very useful instrument at a very low price.

Of course, in enlarging, as in taking a negative, the lens is by far the most important item, and cheap enlargers are, naturally, not fitted with the best lenses possible. Generally speaking, a special lens for enlarging is quite unnecessary, as the lens used in the purchaser's camera can usually be adapted quite well to the purposes of enlarging. If a good anastigmat is available, it will probably serve better than any of the so-called enlarging lenses. If the lantern is fitted with incandescent gas, trouble may be met with if the lens is of very short focus or small aperture. It is not easy to get even illumination with a big source of light, and a small lens or one of short focus, but in a quarter-plate lantern it will generally be found quite possible to work with an  $f/8$  five-inch lens. A four-inch lens will probably be useless, but anything over five inches should be serviceable. For moderate degrees of enlargement, say from quarter-plate to  $12 \times 10$ , an eight-inch lens, in our opinion, the ideal for general use in either quarter or half-plate lanterns. An even longer focal length has advantages, but it necessitates a considerable amount of room, and to get the best illumination a rather longer focus condenser than that usually supplied is advisable.

For larger pictures space can be economised by using a shorter focus lens. A six-inch is a most useful size, but the ordinary five-inch can also be utilised if it has a fairly large aperture. The short focus lens must, however, be of good quality, otherwise it may be difficult to secure good definition over the whole field. With the long focus lens a much smaller angle is utilised, and an R.R. lens will then serve admirably. If a powerful illuminant, such as the arc or limelight, is used, it is advisable to examine the lens before use to see whether its iris is made of vulcanite. If it is, it will probably be destroyed by the heat, and, at any rate, seriously damaged. Such a lens will be quite safe with incandescent gas, but a metal iris or Waterhouse stop is essential if the light gives out much heat, and, of course, a water trough is used.

A difficulty that is often felt when a camera lens is used in an enlarger is the absence of a fine adjustment. The rack and pinion movement of the lantern is generally too coarse for fine focussing, and a lens intended for enlarging is therefore always mounted on a focussing jacket. If a lantern with a fine adjustment to the front is not obtainable, the best plan is to have a lantern-lens jacket fixed to the front. A flange can be soldered to the front of the jacket, and the lens is then readily screwed in place when wanted.

The adjustments of the lantern are few, but there should be ample space for them. The lens should be exactly centred opposite the condenser, and a rising front for the lens is quite unnecessary, though it is provided in many lanterns. If used, it spoils the uniformity of the illumination. Its place is fully filled by a rising and falling movement of the negative, and care should be taken to see that this movement is sufficient. A horizontal movement of the negative is attained by simply sliding the carrier backwards and forwards; this is a very necessary movement, and it should not be interfered with by the useless catches that are sometimes fitted by the makers. Provision for canting the negative sideways is often made, but this is not absolutely necessary, as the same adjustment is quite easily made by pinning up the bromide paper slightly askew on the easel.

A swing movement for the negative is required if the correction of convergent distortion is to be effected, but it should be remembered that the swinging movement complicates the lantern and adds to the cost, while the occasions upon which it has to be used are generally very few. If it is fitted it is necessary to see that it is properly arranged. The axis about which the negative is swung must be parallel with the axis about which the easel swings, and, in addition, it must be possible to tilt the negative sideways in its own plane without disturbing the axis. In some lanterns a side tilt of the negative tilts the axis also, in which case the whole movement is useless for the correction of distortion and might as well be omitted altogether.

A quarter-plate lantern should be fitted with a condenser not less than five and a half inches in diameter, and a half-plate lantern with one not less than eight inches, but these are only the minimum sizes that will cover the plates, and they will only do that when quite close to the negative. Sometimes, through faulty fitting, too much space is left between condenser and plate, and this is a mistake that should be looked for when selecting the lantern.

Another common defect in incandescent gas lanterns is too small a lantern body. For gas the axis of the condenser requires to be rather higher up than is necessary with limelight, otherwise the gas burner cannot be lowered sufficiently; in addition to which the use of a chimney—and one is generally advisable—requires a rather higher lantern body. In a lantern of sufficient size there should be room both for a chimney and for a by-pass fitting under the burner, and the by-pass is an eminently useful adjunct to the apparatus.

A point that should also be carefully considered is the amount of permissible longitudinal movement of the light to and from the condenser. In a quarter-plate lantern it should be possible to put the light anywhere between two and a half and at least fifteen inches from the condenser. This amount of movement cannot, of course, be obtained by simply sliding the tray inside the lantern, the whole body must move backwards and forwards. If the movement is restricted, trouble will be met with in getting even illumination when using lenses of extra long or extra short focus, when reducing, and when enlarging to any very considerable extent.

There is one other point to look to, and, though this may seem a very minor one, it is a detail that at times is of considerable importance. In adjusting the distance of the lantern from the easel it is often convenient to let the lantern overhang the table or other support upon which it is standing. The weight of the apparatus enables this to be done with perfect safety, but unless the baseboard is flat or fitted with continuous side strips to stand upon it is impossible to so arrange the apparatus without tilting the lantern. Many lantern bases are fitted with four ridiculous little feet at the corners, and, therefore, cannot be placed

in an overhanging position at all. If a table or the lantern box is to serve as the support, these feet should be removed and be replaced by continuous rails.

Little need be said with regard to the easel. Rails with a travelling support for the camera and another for a swinging easel are luxuries, but so long as the correction of distortion is not required the swinging easel can be dis-

pensed with. A table will carry the lantern, and a drawing board attached to the wall of the room forms as good an easel as can be desired. Small sheets of paper can be pinned to the board and large sheets can be kept flat by laying a sheet of plate glass over them and securing the board with turnbuttons. A large printing frame forms a very useful easel in these conditions.

## ON CORRECTING FAULTY UPRIGHTS BY COPYING

It is very common in photographs of buildings taken with a hand-camera, to find that the lines which should be upright incline to each other at the top of the picture. A similar failing is not at all rare in photographs taken with a stand-camera, in cases where the building is tall, and there is not sufficient space to plant the camera at a considerable distance. Except with a few modern and somewhat expensive forms of camera, there is rarely sufficient rise of front for a difficult subject, and when the amount of rise is sufficient, the field of the lens may not

intensified or introduced, causing the height to be disproportionate to the width.

Fig. 1 represents a camera, A, pointed upwards to a vertical object B. If now the negative taken in such condition is returned to the camera, and the illumination removed, the object and placed behind the plate, it is obvious that the correct representation of the original could be obtained by placing the sensitive surface in the position occupied by B. It is true that a smaller but similar copy would be produced

Fig. 1.

be large enough for the corners of the picture to be covered by it, when much use is made of the rising front. The use of a swing back which permits the camera to be pointed upwards, whilst preserving the perpendicular position of the plate, or of a rising swing front (which comes optically to the same thing), is to be avoided if possible, as the plane of the plate is not—when

Fig. 2.

Fig. 3.

this device is employed—the same as the plane of definition, and a very small stop becomes necessary if reasonably good definition is to be secured.

It is well known that when copying a photograph of a building in which the lines that should be upright are inclined, the copy may be made to produce these lines as parallel, but unless certain conditions are observed, a fault of another kind will be

Fig. 4.

Fig. 5.

placing the sensitive surface at C or D, provided that it be upright, but horizontally at right-angles to the axis of the lens. In the latter case, however, the picture, if the original negative were used, would be altogether out of focus and hopelessly lacking in definition, unless a pinhole stop were employed.

The equivalent in practice to the example just described keeping of the photograph to be reproduced at right angles

Fig. 6.

Fig. 7.

the axis of the lens and swinging the camera back—or placing the paper-holder—at the angle requisite for obtaining parallel of the uprights. It is an essential point with this arrangement that the lens should be at the same distance from the original as it was from the plate when the original negative was taken, and, therefore, if a copy of the same size is to be made, it is a photograph of a building or any distant object that

tion, a lens of about half the focal length (for parallel rays) the original lens would have to be employed. Such a lens, even possessed, would be difficult to work with, as the inclination of the sensitive surface, together with the large angle included—usually wide for copying purposes—would necessitate the use of an extremely small stop. Fortunately, there is another way, involving the same amount of difficulty.

Fig. 2 is a photograph of a large diagram made for the purpose of illustrating the subject under discussion. It was prepared by stretching bands of black ribbon velvet over sheeting pinned on a frame. The squares, five in height and four in width, are seen to be all alike in both directions. Fig. 3 is a photograph of the same diagram with the camera pointed as would have to be (if without rise of front or swing back) when photographing a high building. The lens was of the rapid symmetrical type, and of about 5 in. focal length, such as is commonly supplied with Kodak and other hand-cameras.

It has been mentioned that when we depend entirely on swinging the camera-back or sensitive surface, the picture to be copied must be at the same distance from the lens that the original was when the original negative was taken. Fig. 4 is a copy of Fig. 3 taken with a lens having a normal focus of 7½ in., and the camera back swung to restore the uprights. The sides

usual kind. Fig. 7 is a copy of the same original, No. 3, made with a lens of 12 in. normal focus, and with the original only swung. With a lens of double this focal length, the diagram (Fig. 3) could not be swung sufficiently to obtain parallelism of the sides, even when the height was dwarfed down to little more than a line.

Fig. 8 is a photograph, such as one often sees, of a house when the camera is pointed upwards to include the whole subject. As there are trees hiding one side of the building, the want of uprightness is not so striking as when perpendiculars are in evidence on both sides; nevertheless, the inclination is sufficiently evident to be objectionable.

Fig. 9 is the photograph of Fig. 8 copied with a 7½ in. lens and with the original swung to obtain uprightness. The house and the children are dwarfed or squatted, and they are much more so in Fig. 10, which was copied with a 12 in. lens. For this last photograph the original was not given sufficient swing to get the uprights quite true. If it had been, the dwarfing effect would have been more strongly marked still.

The relative amount of the swing of the original and the camera back necessary to obtain a perfectly correct proportion

Fig. 8.

Fig. 9.

Fig. 10.

Fig. 11.

have been made parallel, but the height is now too great for width. The dotted line (added since) shows what the true height should be. Fig. 5 shows another copy of Fig. 3 made keeping the camera back square and inclining the picture so that it is being copied. It will be seen that it is much too low for the width. However, this naturally leads to Fig. 6, in which the original and the camera back are swung in opposite directions, and the true figure is restored. This method has the advantage that the double swing tends to accommodate conjugate foci, so that comparatively little stopping is required. It must not be assumed, however, that a mutual adjustment of the swings to obtain the best focus will suffice to ensure exact truth of proportionate height and width. As the copy is rendered much too short by swinging the original, and was even in a less marked degree on swinging the back; when the correctly proportioned Fig. 6 was photographed, the picture was slightly swung, and the camera back more so than would be required for obtaining the best focus.

The amount of deformation (shortening or lengthening in proportion to the width) when either original or camera back is swung, increases, generally speaking, as the focal length of the copying lens is greater than that of the lens used in taking the original photograph, and for this reason a lens of moderate focal length is to be preferred to the long focus lenses generally—and with reason—preferred for making copies of the

of height and width is a question dependent upon conditions existing at the time of taking the original photograph, and these conditions may not be known. But there is a very common case, that of the ordinary hand-camera without swing back or rising front, having a lens of known focal length, where the requisite data for obtaining correctness are at hand. In this case, if a lens is used having such focal length that when employed for making the copy it shall be at the same distance from the plate or print to be copied that the original lens was in taking the picture, the resulting copy will be in true proportion (as shown in Fig. 11) when the camera-back or paper is swung to the amount required for obtaining parallelism of the uprights. As before mentioned, this method requires, when making a copy of the same size as the original, an almost impracticably small stop; and this particular photograph (Fig. 11) was made by swinging both original and camera back, as when photographing the diagram Fig. 6.

When the image is considerably enlarged, not only can a lens of longer normal focus be employed, but the swing of the sensitive surface will not so violently disturb the focus as is the case with a copy of the same size as the original. If the size of the enlarged image is not material, it is comparatively easy to find a lens which will have its focal distance from the negative equal to the distance of the original lens. An enlarged image may now be projected, and the screen swung until the uprights

are parallel. Now take a measure of some details where you can find equal distances in the upright and horizontal directions. These measures will serve as guides when a copy of the same or of any other size is required. The picture and the camera back are swung till parallelism of the uprights is obtained, and then if the height is too great for the width, as

ascertained by the measurements just described, the camera back is less swung, and the original picture more so; or if, is more probable, the height is insufficient for the width, camera back is more swung, and the picture or negative brought more to a right-angle with the axis of the lens.

W. E. DEBENHAM

## THE CONVENTION OF THE PHOTOGRAPHIC ASSOCIATION OF CANADA.

THE thorough planning and consistent effort of the executive of the Association did not secure the response and support that it deserved from the craft at the convention of the photographers of Canada, held in Toronto on August 4, 5, and 6. A good programme of demonstrations was provided, and a fine display of excellent work made by the various paper makers for the benefit of a small and somewhat listless attendance.

The display of members' work was limited: much of it was good and some excellent.

The exhibits of the dealers and manufacturers, however, were more extensive than at any former convention, the paper manufacturers being very much in evidence. In order of effectiveness and excellence of prints can be mentioned the displays of the Kodak Co., The Defender Photo Co., of Rochester, N.Y., The Artura Photo Paper Co., of Columbus, Ohio, and Cameras Limited, of Montreal.

There was a good exhibit of mounts and cards by the Canadian Card Co., of Toronto, and exhibits of apparatus and supplies by the United Photographic Stores, Limited, of Montreal, Ottawa, and Quebec, J. G. Ramsey and Co., Limited, and H. G. Tugwell and Co., both of Toronto. Fisher Bros. and Co. made a good display of frames and mouldings.

The session of the convention began on Tuesday, the 4th. The retiring president, Mr. A. M. Cunningham, in his annual address, briefly reviewed the progress of photography and its increasing applications in the field of industry and in science. The advances in colour photography had been marked, the Autochrome process being a great achievement. Mr. Milton Waide, of New York, gave a demonstration of the Ozobrome process. In the evening a demonstration was given by a Kodak demonstrator of lighting and posing by arc lamp, and development of the exposed plates by the tank method.

On the Wednesday Mr. Charles Wesley Hearn, of Boston, gave an address on "Some Art Principles Easy of Adoption and Pleasing to All Customers."

Mr. A. M. Cunningham, of Hamilton, demonstrated how portrait could be made outside the studio. A demonstration of the Autochrome plates was given by Mr. John Kennedy, Toronto, in place of Mr. M. Schmitz, of the Lumière Company of Paris, who was prevented by illness from being present.

The convention adjourned in the afternoon to attend a picnic at Scarboro' Beach, tendered by the manufacturers and dealers. A thoroughly good time was enjoyed by all.

On Thursday an address was given by Mr. George Graham Hollowell, of Terre Haute, Ind., on "Photographic Fraternalism." Mr. Hammer Croughton, of Rochester, N.Y., spoke "Artistic Improvements of Negatives."

There were demonstrations on the various makes of paper given during the convention.

The Committee on Fire Insurance Rates reported that a board of underwriters assured them that no higher rates were now charged photographers than to other businesses. This does not seem, however, to be borne out by the experiences of photographers, and further inquiries and effort should be made.

Mr. David J. Howell, of Toronto, called attention to "The British Journal of Photography," and pointed out its value to the progressive photographer. He referred to the special of made by the publishers to Canadian photographers of a month's numbers free on receipt of their business card.

The following officers were elected for the ensuing year: President, Mr. J. Frank Jackson, Barrie, Ont.; First Vice-President, Mr. J. T. Leatherdall, Hamilton; Second Vice-President, Mr. Walter Dickson, Toronto; Third Vice-President, Mr. C. A. Lee, Listowel, Ont.; Secretary, Mr. Fred Roy, Peterborough, Ont.; Treasurer, Mr. A. A. Gray, Toronto.

The place of meeting of the next convention will be decided on by the executive committee, composed of the above officers.

A vote of thanks was tendered the dealers and manufacturers for the entertainment of delegates at Scarboro' Beach on Wednesday night.

## IN THE LAND OF MAKESHIFT.

[Queries as to the qualifications to be possessed by a photographer thinking of trying his luck in Canada constantly reach us, and have usually to be answered somewhat generally. We may, therefore, publish the following MS., which reaches us from a reader of the "B.J." who has had to push his way in British Columbia. In more accessible regions and under less severe monetary conditions the photographer could rely on the makers at home, but our reader's note shows the value of being able to help oneself in all kinds of ways when in an undeveloped country.—Eds. "B.J."]

In the belief that some of the expedients to which I have recently been reduced may prove profitable reading, I have ventured to record some of my experiences. On my arrival in British Columbia I found myself minus everything except—an important exception—lenses. I bought a camera, and, in the way of utensils and apparatus, I bought nothing else. Six thousand miles is no joke; it is, in fact, what our Yankee cousins might call a "cash proposition"; but brains, even such as mine, I thought, must count for something.

With the avowed intention of setting up as a "mug-faker,"

with a definite object in view, therefore, I "set to." "gallery" I could not afford to buy, and still less afford to build; so I rented two large 27 ft. by 21 ft. rooms, one facing north-west, the other south-east. That which I selected for studio purposes (with the north-west aspect) has three tall windows, each 10 ft. high. There is no top light, of course, and I am quite satisfied that, except for large groups, the value of the skylight is quite negligible, especially if the windows slant inward at a slight angle—which mine do not.

The next problem was that connected with the construction

room, by which I mean a room as opposed to a cupboard. There were a few old boards about the place, and some odd bits of brown paper of that thick and stodgy variety sometimes used under carpets. By means of an old table-knife and with a hammer I managed to split the boards lengthwise, and these set upright with cross pieces at right angles fixed with formed a structure sufficiently stable upon which to tack paper. This skeleton wall, bounding two sides of a space by 6 ft. of the south-aspected room, enclosed what was to be my developing and enlarging room for many months to come, and, with a little patching and pasting up of the window waste wall-paper, behold! it was dark.

water I had the convenience suggested by the household which I had been careful to annex for my dark purposes. It occupies the corner next the window, I let in to the wall-patching a double thickness of orange paper to work by. The short winter days then fast approaching counselled other devices.

had no red lamp, but I found an old four-gallon coal-oil tin, and a piece of window-pane, and some more orange-coloured paper. I cut out one side of the tin, covered the glass with the paper, and inserted it in slots formed by two strips of wood nailed along the edges of the cut-out side. A small wall-lamp with reflector unmandeered for illuminant, and seven little holes punched in the top of the tin, besides affording good ventilation when the lamp is lit, project quite a decent imitation of the Bear on the white-washed ceiling. This benign constellation of stars at all my evening operations, nor have I found that their influence is other than—well—innocuous. It would be quite possible to nail a metal cover over the perforations, but I have not found it necessary. The ceiling is 12 ft. high. The tin also has a handle at the top which, marvellous to relate, never becomes unbearably hot. The lamp is, therefore, removable at

Among other things I had with me a tiny medicine measuring-bottle of 2 oz. capacity. By careful measurements scratched with

a steel wheel-cutter against the side of a glass jam-jar, I constructed quite a creditable pint-measure.

No dishes! But there were some thin wooden boxes about; of these I made trays with saw, nails, and hammer, and covered them inside with oil-cloth. You soon get used to them, and indeed they are light, clean, and efficient. The cloth requires renewing every few months, that is all, at quite a nominal cost—for British Columbia.

And for all intents and purposes these oil-cloth covered trays are quite water-tight. I have hypo standing in one, month in, month out. The hypo certainly gets into the wood at last, but the water is evaporated quicker than it can leak; and as I keep this dish always in the same place, I have no trouble with respect to contamination. It is quite providential how chemically unclean one can be, provided—but this is nothing to preach about, so the less said the better.

A month or two back I had to make preparations for handling several gross of prints at once, and to this end I converted a long shelf or dresser adjacent to the sink into washing-troughs by the simple expedient of nailing rough boards along the wall and side as well as across their ends. Four yards of oil-cloth did the rest. With such a weight of water as these troughs contained when full, I found a double thickness of cloth necessary. The actual washing is conducted by means of a long half-inch rubber tubing attached to the tap, with an overflow into the sink; and the troughs are emptied by syphoning off through the same tube. To effect this it is only necessary to turn off the tap, disconnect the pipe, and the water flows back into the sink without the smallest need for attention. The tanks are then sponged out, and the washing is done.

For mount-cupboard I utilise the various packing-cases in which sundry of my belongings were hauled over the Canadian Pacific Railway. Every one of my trunks arrived smashed: the locks and hinges were torn off in a fury of unhaste—two months was the time they occupied to travel the distance from Montreal to Vancouver; but the packing-cases arrived immune. Moral: Put your faith in packing-cases—and your goods. These packing-cases, then, I set on their sides—four of them—one on top of another, and used their lids for the construction of shelves. A piece of old chintz curtain now hangs from the topmost, which makes the cupboard fairly proof against dust.

Large sheets of card I was for some time at a loss to know how to store satisfactorily. To keep them on end between the boards they arrived in proved to be inconvenient in other respects. Vancouver is building—fast, and it was not difficult to arrange with a local builder for the gift of three large cases in which plate-glass is stored for transport; these measured 24 in. by 52 in. by 8 in. Set on their sides, and supported on legs made of 3-in. board, they afford excellent service as work-tables, while in the drawer-like interior there was ample room for my 22 in. by 28 in. sheets of card. Only one precaution was then needful: to prevent water during mounting operations trickling through the cracks, their tops I covered with the all-useful oil-cloth.

For drying prints and negatives I have arranged a board 5 ft. long, with two rows of smooth-headed wire nails set lengthwise along and 1 in. from each side. As each nail is placed  $\frac{1}{4}$  in. from its companion, quite a number of prints or negatives can be set up to dry upon it. It occupies practically no space, and is very efficient.

And now I have done, except for one important contrivance which occupies the first place in the studio—to wit, the camera-stand.

At first I started using my field-camera and tripod; but the manipulation of five legs every time a sitter had to be taken finally became insupportable, as they proved too often unsupporting. Buy, I would not. Here to-day, to-morrow—where?—and after my smarting experience of the gentle C.P.R. I determined to lay up for myself no bulky paraphernalia to transport when the time came.

The length of my studio and the focal length of my favourite lens determined the necessity of being able to work right up against the wall for full-length portraits, consequently I must have no backward projections to rob me of space. I must have the up-and-down and all angle movements without cogs, wheels, or, indeed, any system of mechanism which I could not myself contrive. Above all, the stand must not appear too strange a creation to affright the nervous sitter, and, to end up with, I had never done any carpentry in my life! This was the problem I was "up against" (as is said here), and I shall leave to readers who have waded through this sheaf of egotism to declare how far I have succeeded.

After much anxious cogitation, I concluded that my salvation lay in the principles of leverage, and the accompanying photograph will, I hope, elucidate my meaning, if not illustrate a new principle of camera-stand construction.

When placed in position the camera faces the direction on that side of the stand where the two side-levers in the illustration are seen to be connected. By means of the hooks on the back-standards the levers, connected by cross-rods, can be made to assume every angle needful for the rough location of the image on the ground-glass; for fine placing the top lever supports a double platform hinged in front, and this raised by a screw at the back effects the final adjustment.

It will be seen that nearly the whole weight is supported by the lower levers, which are hinged with the top levers at their front extremities, the front standards merely guiding the general movement, which is quite independent of them. This is something of an inconvenience in lowering and raising the

camera; but the camera is not of the heavy type, and habit soon accustoms.

One other weakness must be chronicled. The right-hand back standard is liable to be in the way of the dark slide when intended to be inserted in the camera "landscapewise." In the case a working position for the camera must be found on the stand by drawing it back before focussing is far enough to admit of the necessary after operations. I speak of the needs of my own camera, which is of the "Century" pattern.

There are details of faulty construction which I have had neither the time nor the inclination to modify, as they are easily overcome in practice, and to correct them would necessitate a new model and mechanical contrivances for which I should have to call in expert advice and assistance.

All of which must be taken for what it is worth, not as final, but as a means to an end in the land of makeshift.

For the rest, I frequently see advertisers in the home papers asking for advice and information as to the photographic trade in Canada. Canada is a large place; but from all accounts conditions in the interior and west in British Columbia are not dissimilar. Distances are enormous, material is costly, wages are high; and the handy man will come out on top here or elsewhere.

For myself I have travelled along the lines of resource ably indicated not from choice, but from compulsion. I am not concerned with surprising, but with interesting, others. I have surprised myself—that is all. Hence this screed.

"B. J."—IN BRITISH COLUMBIA.

## A RECEPTIONIST'S CONCEPTIONS OF HER DUTIES.

[In the current "Association Annual," issued as a souvenir of the Convention at Detroit of the Photographers' Association of America, appears a paper by Miss Julia C. Reith, which possesses additional interest from the fact that its author's experience in the reception-room was gained in the service of the redoubtable J. C. Strauss, of St. Louis.—Eds. "B.J."]

RECENTLY a gentleman, who has been a patron of the studio regularly for over twenty years, and with whom I have had many dealings, came in with a friend. He desired to introduce the latter, but hesitated, apologised, and expressed regret that he had forgotten my name. I said: "No, you haven't forgotten it—you never knew it."

I was proud of the incident because it proved that I had handled this customer satisfactorily for a long time, without forcing my own personality upon him. It showed that my interest in the business had impressed him. I think this one of the essential qualifications of a receptionist—the sinking of one's identity in promoting the interest of the studio. I do not mean that one should have no individuality. One should not be a mere machine or an imitator of someone else, but at the same time should not allow one's own affairs, likes or dislikes, or opinions, to enter into the conversation with a patron.

A receptionist should be like a cultured accompanist, probably just as much of an artist as the soloist, but whose personality is lost in a perfect performance.

I believe another essential is to be cordial and courteous to every person entering the studio. One should be attentive, listening to the patron's affairs with interest and sympathy.

I believe that women are, therefore, more successful in the office than men, because they can indulge in small talk and win the approval of customers by being good listeners.

While I regard it necessary to be on the best of terms with patrons, and I appreciate every attention shown me, I never allow these to go beyond words. The receptionist who accepts favours places herself under obligations, which can be repaid only at the expense of her employer. I think it will be found

that the saleswomen who have been continued longest in service are on the most cordial terms with customers during business hours, but their desks are not covered with candies, flowers, or other gifts. These, while usually offered cheerfully, almost compel return favours when orders are being taken. Go to large commercial establishments; the man who steadily advances from the list of minor employees to the management of the business is not the one who has been showered with presents by those with whom he has had to deal.

### Special Visitors to the Studio.

I said that one's personality should be repressed, but this should not be the result of the treatment accorded by her employer. The owner of the studio should make opportunities for her recognition as a person worthy of confidence. I feel that much of the dissatisfaction with receptionists is due to the lack of consideration by the employer. He is only too happy to let her have full sway when the ordinary run of patrons come in, but if someone of importance enters, then Mr. Artist gently hints—no, not always gently—that she had better retire to a seclusion and get busy with detail work. This method prevents the receptionist from getting that broader and more valuable experience, and greater self-confidence which comes from contact with all classes of customers. Another common and very unwelcome practice among employers is to ignore the receptionist when prominent photographers happen to visit the studio. I never hear of a suffer from this; on the contrary, whenever any member of the profession, particularly if he was recognised as one of the leaders, visited us, I was always brought forward, introduced and given to understand, "Here is the man you want to know

was done in such a manner that it left both the photographer myself at perfect ease, giving me an opportunity, by comparison of methods and the interchange of ideas, to profit by his experiences. By reason of this treatment I have become personally acquainted with nearly every member of the profession. My name is known outside of his own community. It has introduced me in them and has led me to become quite familiar with work.

His willingness to have me meet, not only the most important members, but also the most prominent photographers, was but only one of the phases of the complete harmony and fullest confidence existing between the operating room and the office; I do not have any feeling of a sentimental nature, but such perfect understanding that there was not the slightest friction to attract the attention of the sitter.

That I have endeavoured to say necessarily implies that to obtain any fair share of success, a receptionist must be thoroughly in love with her work, enthusiastic in the extreme, will not be at her post early and remain late. One must have intuition and tact, which may be natural or acquired; must be all things to a patron, and, possibly, rather exacting with other employees of the studio who complete the order, but who do not serve the customers, so that the latter will have no reasonable ground for dissatisfaction.

It should be her pleasure to familiarise herself with the names and persons of consequence in the community, so that when such a person enters she recognises the name immediately, a source of great advantage.

### Receptionist and Employer.

It seems to me one reason for poor service in the reception room is the disposition on the part of many employers to make no allowance for occasional errors in the handling of customers. No one becomes proficient at such work until after a schooling and experience which can be acquired only with mistakes. The owner of the studio expects waste and loss when he changes printers or uses some new apparatus or tries a different kind of paper, but he resents any errors in judgment in the office. Many employers also make a grave mistake when they listen approvingly to complaints against the receptionist by a patron. The saleswoman should be absolutely truthful and candid with her employer when a misunderstanding with a customer arises, and he should adjust the difference without disparaging or embarrassing his receptionist in the presence of a patron. Though the receptionist should be treated with justice and some leniency while acquiring efficiency in her work, yet, when she has finally become valuable to her employer, she should not forget that her success has been achieved only by experiences which frequently were a source of loss to the owner. This should make her appreciative of his forbearance and prevent her from feeling that her services and work are underestimated.

Those who are kind enough to follow this rather crude endeavour to regard the receptionist's work from a viewpoint behind the counter, will realise that it would require a volume, instead of a few pages, to do justice to this interesting subject.

JULIA C. REITH.

## ON THE SENSITIVENESS OF PHOTOGRAPHIC PLATES AT DIFFERENT TEMPERATURES.

The following paper, which is a further contribution from Mr. R. J. Wallace, of the Yerkes Observatory, contains the results of tests made with a view of explaining the discrepancy between the results of Abney and King as to the effect of low temperature at the time of exposure on the sensitiveness of a gelatine dry-plate. It is shown that the effect differs in different parts of the curve. We are indebted to Mr. Wallace and the "Astrophysical Journal" for the paper.—Eds. "B.J."]

1895 Abney investigated the effect of temperature upon the sensitiveness of photographic plates, and gave his conclusions in an address before the Royal Photographic Society.<sup>1</sup> His methods and results may briefly be summarised as follows: A special box was constructed so that its temperature could be varied by means of a cooling mixture or a "heated brick" contained the plate under

When at the determined temperature, exposure was made through a square aperture, moving along a slot in the lid, to a small Argand paraffin, or amyl acetate lamp. From measurements of the plates thus obtained, where the light was constant and exposure varied, this investigator found that there was "not necessarily any variance in the gradation of the curves—but that rapidity is altered—although not to the same degree, for each part of plate," being invariably less as the temperature is reduced. With constant exposure to light of varying intensity, he also found that with exposures made above 33 deg. C. the gradation changed, the curve becoming steeper, although up to this temperature the heat had no other effect upon the plate and making it more rapid. In this latter portion of the work, the light used was not exactly the same in the hot and cold experiments, exact values not being aimed for, but merely change in gradation.

Later, E. S. King, of Harvard College Observatory, also made experiments upon the influence of temperature upon sensitiveness,<sup>2</sup> and exposed two portions, cut from the same plate, to temperatures of "about 0 deg." and "about 80 deg.," obtained by placing one outdoors, and the other over a hot-air "register"

until the plates had taken the temperature of their surrounding air. They were then exposed for one minute to the extra-focal image of *Polaris* in the telescope. In the case of the cold plate the "focus was set to reduce the light by one-half magnitude." It was found on development that the images were of similar density, showing that "the difference in sensitiveness for a change of about 70 deg. or 80 deg. is 0.5 magnitudes, the cold plate being the more sensitive." From further experiments it "was found that temperature not only affected the sensitiveness of the plate, but also changed the gradation of the intensities of darkening."

When the results of these investigators are compared they are almost directly opposed to each other. The work presented in this paper was therefore undertaken in the hope that a greater concordance might be obtained by working under definite conditions.

### The Method of Testing.

The plan of work will first be noticed, as it will assist in the clear understanding of the results. Plates were exposed in a temperature-box constructed for this purpose, somewhat similar to that used by Abney, at temperatures varying from +100 deg. to -14 deg. C., and were developed and fixed under precisely similar conditions. Another series of exposures under natural conditions of temperature, and varying from +24 deg. to -14 deg. C., was made to corroborate the laboratory results with artificial temperatures. The negatives thus obtained were measured with the spectro-photometer especially constructed for such work, and detailed in a former paper,<sup>3</sup> and curves were plotted show-

<sup>3</sup> "Astrophysical Journal," 25, 124, 1907.

ing the relation between exposure and density for each variation in temperature.

### A Temperature Box

The design of the temperature-box will be understood by reference to the plan which is given herewith (Fig. 1): *A* is a zinc-lined box about 12 inches square, closed by the light-tight lid *B*, which carries with it the cubical plate-chamber *W*. This chamber contains a transparent scale-plate *D*, which rests in

Fig. 1.

contact with the surface of the sensitive plate *E* under test. This sensitive plate is held in position by means of a light wooden frame *K*, in which is fitted a piece of deep-ruby glass *F* to avoid action from scattered light inside the box *A*. Light is obtained from an acetylene burner at *L*, and reflected down by means of the mirror *M*, through the ground-glass *H*, and thence passes to the sensitive plate. A thermometer *T* is inserted so that its bulb rests in contact with, and presses against, the sensitive surface. Increase in temperature is obtained by leading the 110-volt direct current through the two resistance coils *RR'*, which

Fig. 2.

run the entire length of the box. For reduction in temperature many experiments were made with various freezing mixtures, and also with ether spray and liquid air, which were introduced at *O*.

The scale-plate used was a negative strip developed from an exposure to the revolving sector-disc machine. The method of exposing through a transparency was selected as being most desirable, as by this means there is obtained a constant exposure to light of variable intensity, thus duplicating the conditions under which one works in the case of exposure at the telescope,

or in general camera work. The dimensions of the transparent portions of this scale-plate measure 6.5 by 2.7 cm., while the plates used were 8 by 10 cm. The use of the sector-disc machine itself would have been still better, but the impossibility of making use of it without practically rebuilding it led to the abandonment of the idea.

### Artificial Light.

The light used was acetylene, prepared in a Colt generator water-to-carbide type, and burning from a  $\frac{1}{2}$ -ft. Halm burner

Fig. 3.

under a uniform pressure of  $2\frac{3}{8}$  inches of water. In front of the flame, and separated from it by a distance of 11 mm., a metal plate is supported from a cylindrical metal chimney, this plate being pierced with a circular aperture of 2.5 mm. diameter. The aperture is at such a height that its position comes immediately in front of the centre of the white portion of the flame. The burner is fed with gas which passes from the generator, and then through a large bottle containing caustic potash; a manometer indicates the pressure.

If (as has been pointed out by previous writers) care be taken not to turn down the flame at the burner, but to cut off the gas

Fig. 4.

supply abruptly, this arrangement forms an exceedingly good intensity standard, in cases where the spectral quality is suitable. In the present work no compensation colour-filter was made use of, as the spectral distribution of the light intensity was of no moment, and was used with similar plates throughout. Generators of the carbide-to-water type are unsuited unless equipped with some form of pressure governor.

### Exposure, Development, and Precautionary Measures.

The primary object of the investigation was its relation to the photography of faint celestial objects, only one make of plate was experimented upon, viz., "Seed 27 Gilt Edge," which was selected because of its uniformly greater speed. The exposures were made by first dividing them into three groups according to the temperatures, as follows:

from + 24 deg. C. to + 100 deg. C. } (Laboratory exposures)  
 from + 24 deg. C. to - 14 deg. C. }  
 from + 24 deg. C. to - 14 deg. C. (Outdoor natural temperature exposures)

The actual handling of both groups A and B, separate sets of plates, all of similar emulsion number, were exposed at each of the following temperatures: (A) + 24 deg., 50 deg., 75 deg., 90 deg., 95.5 deg., and 100 deg. C., and (B) + 24 deg., - 2 deg., and - 10 deg. Besides, several 8 by 10 plates were cut into six pieces, and the resultant smaller sizes were

Fig. 5.

exposed similarly, care being taken that each plate of the sets was exposed at a different temperature, thus assuring comparison with each other.

The exposure given to each plate was carefully kept constant to save the actual temperature of the plate itself. The distance of the flame-diaphragm from the centre of the mirror was 35 inches, and the duration of exposure was 3 minutes, carefully timed by means of a stop-watch.

After exposure of any one group the plates were removed from the temperature-box, numbered, and laid face up in an open plate-box for a few minutes, until they had assumed the temperature of the room, and then replaced in their original position until all of the units of that group were completed.

A set of plates was developed at the same time, the developing agent being rodinal, which was used at a dilution of 1:4; the temperature of development was 20 deg. C., and the duration of time 3 minutes. Some few of the sets were purposely developed for a shorter time—down to 1 minute 30 seconds—in order to make certain that a difference in  $\gamma$  would not affect the final result. In every case the plates were first soaked, immediately before development, in a large quantity of distilled

water (temp. 20 deg.) in order to ensure the certainty of equal temperature for each plate.

In the case of the plates exposed at reduced temperatures, by the aid of freezing mixtures of ice and salt, etc., the exposure of the plate for some time in the box, to enable it to assume the necessary temperature, gave rise to the idea that the presence of so much aqueous vapour might give disturbing results, even although the plate itself, by reason of its position in the inner chamber, seemed to be protected therefrom. However, the action of water vapour was investigated in the following manner: A  $3\frac{1}{4}$  by  $4\frac{1}{4}$  plate was cut into two strips, one of which was soaked in distilled water for 3 minutes, and then removed, drained, and placed in the plate-holder side by side with the dry slip, and both were immediately subjected to simultaneous exposure. Both plates were then soaked in water and developed.

Examination during development shows that the image appears with equal rapidity on both strips, but as development progresses the "dry" slip becomes apparently more dense. Ex-

Fig. 6.

amination of the fixed and dried negatives confirms this greater density. Measurement of the plates furnishes data for the construction of the accompanying curves (Fig. 2), from which it will be seen that the general speed is reduced by  $2^{0.5} = 1.4$  times; the curves, however, do not cross, but appear to be shifted along the log  $E$  axis and parallel to it. From the temperature-curves, which will be shown presently, it will be seen that aqueous vapour (if present) therefore does not alter the result. This experiment was several times repeated, for varying times of preliminary immersion, with uniform results.

Any distributing influence of the ether vapour upon the sensitiveness was also investigated, but with negative results: even bathing in sulphuric ether appears to have no effect upon either  $D$  or  $\gamma$ .

In the course of the work it was also necessary to determine the influence of soaking in water prior to development, as some of the test plates were developed without this initial soaking. Experiments upon a sector-disc exposure, where the plate was cut in half before development, and one portion soaked in water, showed, when both parts were developed together, that the image appears first upon the dry half and seems to have greater vigour

As development progresses, the wetted plate rapidly overtakes the other and (by ruby light) soon no difference is discernible. Measurement of the plates, however, confirms the results arrived at by Mees and Sheppard, viz., the wetted plate has a higher  $\gamma$ , and is likewise shifted along the log  $E$  axis,<sup>4</sup> but this does not influence the temperature test results.

Fourteen duplicate sets of plates completed the laboratory experiments, of which eight sets were of Group A. Preconceived opinions held by various observers regarding the influence of temperature upon sensitiveness necessitated verification of the laboratory results by exposures made at duplicate temperatures under natural conditions. For exact quantitative work exposure at the telescope on "extra-focal" images could not be considered, as uniformity of photographic light intensity is impossible; for, while an experienced observer is able to detect a certain amount of atmospheric "thickening," yet he cannot make any reliable measure of the same, nor can he say what absorbing influences are present at any time during the work, particularly in the more refrangible wave-lengths, the region of greatest photographic activity.

For this reason, therefore, a separate arrangement was made, which is shown in outline in Fig. 3.  $A$  is a rectangular wooden box into which fits the plate-holder  $B$ , while a flap-shutter,  $C$ , controls the length of exposure. Light is supplied from the constant acetylene burner at  $D$  (this burner being the same as was used for the laboratory tests). The light was used at a constant distance of one metre from the plate surface, and fits "light tight" into the end of the brass tube  $E$ .

In practice the scale-plate (which was the same as used in the foregoing experiments) was placed in contact with the sensitive plate in the plate-holder. The entire apparatus and the plates intended for use were placed out-doors in the open air some hours prior to their exposure, and arrangements were also made for changing plates out-doors. As a rule, six exposures were made out-doors at low temperature, followed by six exposures in the laboratory at "normal" temperature. Altogether, Group C covered eleven sets of plates, averaging four to eight plates to a set. As with Groups A and B, each set of Group C was developed at one time, under constant conditions as previously described.

The laboratory experiments connected with this work were begun in the early part of 1906, but the natural temperature verifications could, of course, be performed only during the winter months, and were conducted at various times during 1906-7 and 1907-8. These past two seasons have not been characterised (at this location) by very low temperatures, but sufficient data have been obtained to give almost uniformly concordant results.

#### Method of Recording Results.

When all of the principal plates had been measured in the photometer, the densities for each of the plates corresponding to similar temperatures were combined, and a mean was obtained. This tabulation showed a good agreement between each of the plates, there being no error greater than that which could be ascribed to the local variations of the plate coating. It is not necessary that these results be given *in extenso*, but Table I gives an example which may serve well as a specimen.

TABLE I.

Plate.	Measured Density of the Corresponding Strips.								
	1	2	3	4	5	6	7	8	9
A .....	0.0719	0.3642	0.8632	1.3019	1.6441	1.8064	2.1117	2.4012	2.5312
B .....	0.0691	0.3819	0.8679	1.2729	1.6262	1.8756	2.1149	2.2921	2.4160
C .....	0.0712	0.3687	0.8555	1.2100	1.5037	1.8621	2.0960	2.2115	2.4322
Mean .....	0.0707	0.3716	0.8722	1.2616	1.5580	1.8480	2.1082	2.3016	2.4598

(<sup>4</sup>) "Journal of the Royal Photographic Society," 47, 88, 1907.

The mean densities thus obtained, when plotted on square paper, with the density as ordinates, and the abscissae as exposures, give the sensitiveness-curves for the temperatures considered. Fig 4 shows the curves of temperatures + 24 deg. 100 deg. C., while Fig. 5 shows the effect of reduction from + 20 deg. to - 20 deg. C.

#### Results.

In these curves representing temperature increase, it will be noted that between the temperatures of 24 deg. and 75 deg. the curves cross one another: this is the "alteration in gradation" spoken of by both Abney and King. In the opinion of the writer it is this "alteration" which accounts for the discordance between the findings of these workers. According to Abney increase in temperature results in added speed, while according to King, greater speed, even to 50 per cent., is obtained by decrease in temperature. In reality, then, it simply depends upon which portion of the curve is taken as to whether the speed is increased or reduced, i.e., whether one considers faint objects with consequent low photographic densities, or bright objects with full exposure and consequent high densities.

In the negatives obtained, the development was such that the "straight portion" of the characteristic curve embraced about five magnitudes. As the densities of a photographic negative throughout this "straight portion" are proportional to the logarithm of the light received, then it is sufficient to multiply  $D$  by 2.5 in order to convert it into stellar magnitudes. Such magnitudes, however, will not be absolute, but merely relative as they are based upon the light used in the course of the investigation, and will vary according to the initial intensity, for, as is well known, the photographic plate does not follow a straight line law with reference to intensity.

Thus, from this point, where the curves cross, the plate comes slower for fainter stars as the temperature is increased while under the same conditions the plate is faster for the brighter stars. Beyond a temperature of 85 deg. C. the plate breaks down, and a considerable amount of fog is induced which increases very rapidly with a further slight rise, until at 100 deg. C. it is very heavily veiled and badly mottled. Measurement of the plates taken at this temperature presented considerable difficulty. The actual "fog value" of each plate was, of course, subtracted from the densities before plotting.

Taking the case of the curves representing the plate values for the temperatures of 24 deg. and 50 deg., we see from the mean separation of the curves  $D_{50} = 0.06$ , which amounts to 1.04 times less chemical light action on the heated plate than that at normal temperature, for the fainter stars; while on the other hand, for  $D_{24} = 0.95$ , the action is increased 1.9 times. Between 24 deg. and 100 deg. the mean difference is  $2^{3.5}$ , or 11 times general reduction in speed.

The original scale-plate and the negatives therefrom possess nine separate shades or tone-values, and defining them from the weakest to the most opaque as  $D_1, D_2, \dots, D_9$ , we may carry the method of recording results a step farther and re-plot each in terms of  $D_n$  and temperature, and thus afford a ready connection to everyday routine work. Such a series of curves is shown in Fig. 6.

In the preparation of this figure, all of the curves for "normal" (+ 24 deg. C.) to + 100 deg. C. were first plotted and then all of the values of  $D$  for temperatures lower than + 24 deg. were reduced to a mean  $D$  for each point, and shifted vertically to connect. As has already been stated, the magnitude value of the change in  $D_n$  with temperature cannot be referred to an absolute scale, because in quantitative photographic astronomical work, the value of the intensity recorded is dependent upon (a) the atmospheric absorption, tremor, etc., and the length of exposure. Care with reference to the development constants eliminates these (relatively), so that to consider

(<sup>5</sup>) Accompanied by reversal in the lower values of  $D$ .

image in terms of  $D$  it simply remains to read off the corrections necessary for temperature.

badly considered, it may be stated that for images at about minimum of photographic action, the sensitive plate is faster out 0.35 magnitude in a temperature range from  $-18$  deg. to  $+32$  deg. C. ( $0$  deg. to  $+90$  deg. F.) and for high values of  $D$  (corresponding to the brighter stars) about magnitude slower, while for stars of medium density (corresponding to the value of about  $D = 1.2$ ) there is no apparent effect.

On the examination of the measurements and curves of entire series of plates, the writer is forced to the conclusion there is a limited range of temperature at which this added error for light of low intensity is apparent, and that at other temperatures, either above or below this region, the sensitive-plate curve falls rapidly and smoothly. In other words, photographic sensitiveness plotted against temperature may be represented by a curve similar to the probability curve. This idea comes out when we consider the curves already shown, where.

in the higher temperatures, there is a certain point above which the plate curves fall off from the normal and are moved bodily along the log  $E$  axis; precisely the same effect is indicated in the case of temperature reduction curves representing successively lower temperatures. This is to be expected when consideration is given to the classic experiments of Dewar, who showed that there was a very great decrease in sensitiveness at temperatures about  $-200$  deg. C. The influence of temperature upon general velocity reactions would also point to a similar conclusion.

The points dealt with in this work require extension with special apparatus, by (preferably) other investigators, at temperatures intermediate to  $-10$  deg. C. and  $-200$  deg. C., as it would be desirable to acquire data relative to the formation of the rising branch of the curve. It should also be pointed out that it by no means follows that the region of maximum is identical on plates of different chemical constitutions, or that difference in wave-length may not modify the conclusions arrived at.

ROBERT JAMES WALLACE.

## ANIMAL PHOTOGRAPHY FOR THE PRESS.

"Down-Town Topics," a monthly sheet issued by the Oberg Camera Co., of New York, the Editor of an American magazine, contributes the following notes on the branch of photography particularly associated with his own work. As a points out, a knowledge of breed characteristics is as important to the animal photographer as the skill required to present them in the photograph.]

Patience is required to get a good livestock picture than to photograph any other subject. Well-bred animals are "high-strung"; their nervous development is such that when they are even mild excitement it seems impossible for them to stand still. When led out before the camera they quickly realise something unusual is going on, and they are prone to assume all the awkward attitudes possible. A few show animals have been trained to stand in positions studied to show them to the best possible advantage, but such animals are scarce. Only a domestic animal that is valuable enough to be worth photographing is excitable and often almost ungovernable at times.

I prefer a 4 by 5 film camera, and I have done some of my work with a rapid rectilinear lens. A tripod and ground glass are absolutely worse than useless. You must know your animal, and you must know your distance.

The best light is during June, July, and August, either before or after three in the morning or after three in the afternoon. It is difficult to get a good animal picture in winter.

Overhead sun is not a good light, because the lower parts of the animal are partly obscured in shade. A photograph consists of light and shade, a careful study of which is necessary to show the contour of muscle and development of bone sought by the breeder.

A study of breed and breed characteristics is essential to real success in this line, but the operator may gather a few important points by talking with the breeder a few minutes before posing the animal. The conformation of a race horse is essentially different from that of a drafter; dairy cows are very unlike beef cows in shape. The value of an animal may vary to the extent of hundreds of dollars by the addition of a few pounds of flesh just where it is wanted.

The best position that is better than all others is to face the animal almost directly toward the sun, with just enough deviation to show lights and shadows along the side of the animal and toward the camera. Then stand with the camera opposite the head of the animal so the rays of sunlight will pass the lens at right angles. It is safer to shade the lens, which may be done by holding your hat in the direction of the sun, or by standing between the camera and the sun. When an animal

is placed in this position the sun glances along its side, illuminating the face, neck, front of the legs, shoulders, hips, and swelling muscles wherever the sun strikes them. The point of a livestock photograph lies in the head and face; for this reason the face should be turned slightly toward the operator, not too much, but just enough so the forehead, one eye, and both ears show; unless for some specific reason a profile of the head, neck, and one ear is required. The face and head of an animal show character and disposition, which often indicates, in young animals, both the temperament and development that may be expected.

Remember that these directions are given for half-tone work. An artist who merely wants a pretty picture may criticise this manner of intensifying the lights and deep shadows because he feels that it suggests improper colours, but the proper colours are conveyed to breeders by the breed characteristics and by the markings of individual animals. Then the engraver wants all the contrast he can get, and if you want a good half-tone you must furnish the sharpest negative possible. The best photographs lose in the process. You may count the hairs in a photograph, but you will hardly see them in the cut. The foolish fad that influences judges to award premiums to poor, hazy photographs meets with little courtesy from publishers.

It may require half an hour to get an animal in proper position with its legs gracefully posed and the weight equally distributed on each foot, but when the time comes you must be ready with the proper distance, the camera about three and one-half feet high at right angles to the length of the animal, ready to snap it instantly. With a rapid rectilinear lens I use an *eight*\* opening with the shutter set to the fiftieth or one-hundredth part of a second. I seldom pose the animal more than once, and I seldom fail to get a photograph that will make a satisfactory half-tone. You can take pictures of animals in all kinds of positions and with a very inferior light, but the final results are usually very unsatisfactory to the breeder and to the publisher.

Some photographers take advantage of the idiosyncrasies of

\* This may mean either  $f/8$  or the U.S. 8 No., which is  $f/11$ , but in any case the exposure seems to be unduly short, for at any rate the latitude of the United Kingdom.—Eds., "E.J."

their cameras to exaggerate certain parts of an animal. It is generally recognised, for instance, that a good dairy type of cow is, as the breeders say, "wedge-shaped," with hind parts very heavy in proportion to shoulders, neck, and head. Some photographers, to emphasise this peculiarity, photograph a cow from a backward position, the result of which, if used for selling purposes, is not only an attempt at dishonesty, but one so apparent that it defeats the object of the operator.

I have taken my best livestock pictures on hilltops with nothing in range beyond but a grey sky. Of course, a white animal may be taken with a dark background, but you seldom find a white domestic animal worth a picture. Ninety-nine out of a hundred are at least partly coloured. You may paint out the objectionable background, but it is much more satisfactory to leave it out. The picture of the animal itself cannot be retouched without spoiling it. Engravers prefer P.O.P. prints, not too glossy.

HERBERT SHEARER.

## Photo-Mechanical Notes.

### Half-Tone Screens.

The use of ruled screens formed by waved or undulating lines is put forward as an advantageous process by Andrew Dargavel, of 14, Anson Road, Cricklewood, London, N.W., by whom the method is described in Patent Specification No. 17,069, 1907. The half-tone plates are prepared by means of a screen, which may consist of glass or other suitable material, such as gelatine or celluloid, but preferably plate-glass, and is provided with lines of a similar curved or undulating character. These lines may be produced on the glass by any of the known methods, such as by photography or by means of a steel or diamond cutter, by hand, or by machinery, and arranged in parallel series, or the series of lines on the screen may be arranged so as to intersect or cross each other. The lines may be ruled either in a single series of parallel waved lines, or by a double series of waved lines, the lines of the second ruling being ruled in such a way that they cross or intersect the lines of the first ruling. The lines of the second ruling may cross the lines of the first ruling at right angles or at any other angle which may be found necessary or convenient. The lines of the first ruling may be waved, and the lines of the second ruling—that is to say, the ruling which crosses or intersects the first ruling—may be waved or straight, as desired. The lines of the rulings may be of equal thickness or of varying thicknesses, and the lines may be separated by equal or unequal spacings; the spaces may be equal to the thickness of the lines, or be varied in any desired manner. Moreover, the waves of the lines themselves may be evenly disposed, of slight or pronounced character or of varying lengths and widths, according to the effect required in the finished picture.

By using a screen of this improved type, the lines, which enable the half-tone effect to be obtained, conform more readily to the lines and curves of the subject or picture, and therefore ensures a better rendering than is obtainable with screens having straight parallel lines as ordinarily employed. At the same time, the mechanical appearance of the screen in the reproduction—a common defect in "half-tones" produced by the straight line screen—is to a large extent obviated.

### PHOTO-MECHANICAL PATENTS.

The following patent has been applied for:—

**HALF-TONE NEGATIVES.**—No. 17,215. Method of making half-tone negatives for relief blocks. Niels Bendixen, 321, High Holborn, London, W.C.

"PATENTS AND DESIGNS."—The first issue of this periodical dealing with patent matters as governed by the new Patents and Designs Act, 1907, has been issued from 5, Tavistock Street, London, W.C. The journal deals with notable new inventions and with patent cases in the courts.

### FORTHCOMING EXHIBITIONS.

September 11 to October 24.—Photographic Salon. Entries close August 31. Sec., Reginald Craigie, 5A, Pall Mall East, London S.W.

September 17 to October 24.—Royal Photographic Society. Entries close September 1. Sec., J. McIntosh, 66, Russell Square, London, W.C.

October 13 to 17.—Southampton Camera Club. Entries close October 6. Exhibits by October 8. Hon. Sec., S. G. Kimber, Oadene, Highfield, Southampton.

October 14 to 17.—Rotherham Photographic Society. Entries close October 5. Sec., H. C. Hemmingway, Tooker Road, Rotherham.

December, 1908, to January, 1909.—Kiew International Photographic Sec., S. T. Horovitz, Technical Society, Kreshtchatik, 10, Kiev Russia.

1909.

January 6 to 27.—Northern Photographic (Manchester). Entries close December 11, 1908. Sec., S. L. Coulthurst, Broad Oak Road, Worsley, Manchester.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications have been received between August 1 and August 15:—

**LANTERNS.**—No. 17,027. Improvements in optical lanterns. William Laurence Parkinson, 15, Water Street, Liverpool.

**COLOUR PHOTOGRAPHY.**—No. 17,065. Method of producing multi-colour filter screens for the production of photographs in natural colours. Jan Szczepanik, 55, Chancery Lane, London.

**CINEMATOGRAPH.**—No. 17,110. Improvements in apparatus for producing animated pictures. William Barmingham, 55, Mark Lane, Street, Manchester.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**ORTHOCHROMATIC PLATES.**—No. 17,453. 1907. The invention relates to the use of tartrazine in the plate in such a way as to form a yellow screen for the colour-sensitive emulsion, that is to say, plates are prepared for ordinary photography by embodying tartrazine in the film, which enables the plate to act as its own screen. There are two known processes for dyeing plates. One consists in simply dipping a sensitised plate in a dye solution, the other in embodying the dye in the sensitising emulsion before the emulsion is applied to the plate. The former process of dyeing is somewhat unsatisfactory, for not only is it expensive, but there is not uniformity in its results, since the amount of dye taken up by the plate varies with the condition, as well as with the external conditions prevailing during the operation.

For the purpose of the present invention, therefore, a quantity of tartrazine is added to and mixed with the emulsion, and the mixture so produced is applied to the plate or film, and allowed to dry thereon. The plate or film thereby forms a screen for itself and when dry is ready for use.

It is found that by adding 5 c.c. of a solution of tartrazine (containing about 1 gramme of the colouring substance in 40 c.c. of water), to 200 c.c. of emulsion, a mixture is obtained which is every way suitable for the purpose of this invention.

The composition of tartrazine and its chemical series are given in any good work of reference on dyes or colouring matters; in "Dictionary of Dyes, Mordants and other Compounds used in Dyeing and Calico Printing," by Rawson, Gardner and Laycock (published by Charles Griffin and Co., Ltd., of London) tartrazine is given as the sodium salt of diphenyl p. sulphonic acid oxazodiox tartaric acid. Thomas MacWalter, Colnbrook, Granville Road, High Barnet, Herts.

SS-PLATE CINEMATOGRAPH.—No. 3,987, 1908. The invention relates to the production and exposure of collodion or albumen sensitive plates of fine grain sufficiently sensitive to be used for small pictures in a plate cinematographic projector. The series of pictures to be reproduced on these plates are taken in the ordinary way on film, and the negative film having been developed, is passed through the projection instrument. This instrument is provided with a projection lens arranged in line with the axis of the reducing lens of the camera for the movable plate. The reducing lens throws upon the plate an inverted negative image reduced to the desired size. The two pieces of apparatus being connected synchronously and the objective of the camera alone comprising a shutter or stop, each time the film is fed forward and exposed movable plate will be fed forward and exposed. The operating handle for the two appliances enables the speed of the displacement and therefore the time of exposure to be controlled. Each view of the band of film will be received upon a small surface on the movable plate; when the entire surface has been exposed, all successive images on the band of film will have been reproduced as adjacent microscopic photographs.

It may be preferable to obtain a plate with negative views by means of the band of film, this plate then serving for the reproduction by direct exposure of as many positive plates as desired. In this case, instead of running a band of negative film through the projection apparatus, it is sufficient to pass a band of positive film through it.

One of the two instruments is adapted to be slid by means of a rack meshing with a rack in slides provided on the platform,

the object of the relative regulation of the horizontal distance between the two instruments; absolute regulation is obtained by causing the lenses to advance or recede.

The two instruments are operated simultaneously by means of a driving or extension rod in order that it may be able to follow variations in the interval separating the two instruments when it is being adjusted. The extremities of this rod are respectively solid with the shafts of the operating gears for the camera and the projection instrument.

The photographic camera for the movable plate may be of any type. Nevertheless, as the images to be produced are microscopic, it will be understood that the precision of the mechanism must be absolute. With this object the inventors have devised the following apparatus:—

The plate *a* is fixed in a frame *b* capable of vertical displacement in slides *c*, which form part of an accessory which is itself capable of displacement on the fixed horizontal slides *d*.

These displacements are regulated in such a manner that the successive views of the lower horizontal row of the plate first of all pass in succession in front of the lens, the plate moving in the

direction indicated by the arrow 1; at the extremity of this row the plate is depressed by the height of a view; the plate is then again displaced horizontally, but in the opposite direction to the arrow 1, and all the views in the second horizontal row pass in succession in front of the lens; at the extremity of this row the plate is again depressed and the third row of views is level with the lens. In this manner the plate is subjected to a reciprocating horizontal movement regularly interrupted at the end of each travel by a depression corresponding to the height of a view. The movement is produced by a handle, *e*, driving a toothed pinion *f*, which meshes with a gear wheel *g*.

The gear wheel *g* carries on one of its faces in proximity to its periphery, a series of reliefs, the uniform arrangement of which serves to produce sinuous paths, *h*, in which pins *i* engage; these pins correspond in number to the views in a horizontal row on the plate, and they are provided on a horizontal bar *j* solid with vertical slides *c*. The direction of the sinuous paths *h* is inverted in each half of the wheel *g*, in such a manner that a complete rotation of this wheel produces a displacement of the bar *j* and consequently of the plate *a*, first in the direction indicated by the arrow 1 and then in the opposite direction. The bar *j* is guided in its displacements by the rollers *k*. In addition to the reliefs indicated, the wheel *g* is provided (at one only of the places at which the direction of the paths *h* changes) with a boss *l* acting at each semi-revolution of the wheel, alternately upon each of the rollers *m* and *n* solid with the whole constituted by the vertical slide ways *c*, the bar *j* and a device located in front of the plate holding frame *b*, which serves to support the latter.

This arrangement comprises a plate *o* solid with the part of the system which is movable in the horizontal direction; this plate is slotted at *p* and *q* in such a manner as to form graduated slots in which a certain number of pins *r*, fixed on the uprights or vertical parts of the frame *b*, are able to engage. Stops *s* are formed in the slots *p*, *q*, and the pins *r* enter these stops after each vertical displacement of the plate. The vertical interval between two consecutive stops *s* is equal to the height of a view, reckoned from the centre of the lower view to the centre of the view above it.

Taking the apparatus at the beginning of the projection as represented in fig. 1, if the handle *e* be turned in the direction indicated by the arrow 3, the gear wheel *g* is driven in the direction indicated by the arrow 4. The first pin *i* of the bar *j* traverses the sinuous path *h* in which it is engaged; in doing so it reaches *h*<sup>1</sup> where the path forms an incline; the wheel *g* continuing to rotate, as will be understood, a tractive effort is produced upon the bar *j*, and the part of the system which is horizontally displaceable moves in such a manner that the second view of the first horizontal row moves in front of the lens. At the same time the second pin *i* of the bar *j* has entered the following sinuous path; a displacement similar to the preceding one is produced. All the pins *i* come in succession in a path *h*; when the last pin is thus engaged the plate has reached the limit of its travel in the direction indicated by the arrow 1 and the wheel *g* has made a semi-revolution.

At this moment the boss *l* encounters the roller *n* which has been displaced simultaneously with the plate. The effect of this encounter is the displacement of the plate *o* relatively to the frame *c* and consequently to the plate-holding frame supported by the frame. The pins *r* leave the stops *s* and, sliding in the inclined paths of the groove *p*, fall into the lower stops. The plate has been depressed to the extent of a row of views.

As the wheel *g* continues to rotate, it presents to the pins *i* sinuous paths *h* of inverse direction; the bar *j* moves intermittently in the opposite direction to that indicated by the arrow 1, and as regards the second horizontal row the views present themselves in front of the objective in the same order.

When the wheel *g* has effected a complete revolution, the boss *l* encounters the roller *m* and the plate is again depressed. The operation is the same until all the views have passed in front of the objective in the order set forth.

The shaft *t*, which carries the gear wheel *g*, is hollow. When the apparatus is used for photographing the images of a band of film on a reduced size, the tubular shaft *t* is closed in front by a screw plug *z*. The luminous rays then pass through the objective *u* and fall on the plate where their area is limited by the window *v*<sup>1</sup> formed at the extremity of the cone *v*<sup>11</sup>.

When the apparatus serves for projection, the plug *z* is unscrewed and the rays of an appropriate source of light pass through the tubular shaft, the plate, the window and the projection objective in the opposite direction.

The shutter *v* with four screens *v*<sup>1</sup> is actuated by the toothed pinion *x*, which meshes with another pinion *y*, keyed upon the shaft *t* of the gear wheel *g*. Jean Leon Muller, 8, Avenue Berthet Sannois, and Jules Rousset, 27, Cours Marigny, Vincennes, France.

## New Trade Dames.

**PHASTOLITE.**—No. 304,226. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives. Sissons Bros. and Co., Bankside, Sculcoates, Hull (varnish and paint manufacturers).

**RELWOD.**—No. 304,323. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives. J. Irving Rogers and Co., merchants, Windsor Buildings, George Street, Liverpool.

**CINEMA PATHE** (with drawing of two cocks).—Nos. 298,894 and 298,895. All goods in class 8, but not including electrical cables, photographic cameras, and other photographic apparatus. Compagnie Générale de Phonographes, Cinématographes et Appareils de Précision, 98, Rue de Richelieu, Paris.

**MADDOTYPE.**—No. 304,183. Photographic prints. Charles Worcester and Co., 5, Kingsdown Parade, Kingsdown, Bristol.

## New Books.

"Colour Photography," Special Summer Number of "The Studio." London: "The Studio" Office. 5s. net.

"The Studio" has always done its best to afford photography a status among the fine arts, and this portly volume is the latest effort of that important journal to further the claims of the camera amongst artists and other people of taste. The full title is "Colour Photography and Other Recent Developments of the Art of the Camera," but as there are five times as many monochrome illustrations as there are coloured ones, we can very well deal with the book here in a short review and speak at greater length upon the coloured work and the article by Dixon Scott in our own "Colour Supplement," which is due September 4. Pictorial work in monochrome is not alluded to in the letterpress; we need, therefore, only refer to the illustrations. They are gathered from all sources, and include work as early as that of David Octavius Hill, and as recent as that of Malcolm Arbuthnot. On the whole, we consider the monochrome section by far the most satisfactory; the coloured work is not delightful in any instance. That fact is due, perhaps, to another, which is that the original source of most is the Autochrome plate, satisfactory reproduction of which appears as yet to be difficult.

A leisured examination of this book induces the feeling that names and reputations count for too much in pictorial work. The cases are really few in which one honestly admires a picture first and then discovers it to be by some one with a reputation afterwards. The case of Robert Demachy stands almost alone in this respect. His "Honfleur" is true landscape art in its modern aspect, and his "Seine at Clichy" is fine decorative landscape. But there are many names quite new to us which sign pictures of great merit and charm. We are confirmed in our previous opinion that Paul Pichier leads in the matter of fine romantic feeling, arresting and faultless design, and strength of motive, in outdoor pictures. His "Steps at the Villa d'Este" has great pictorial quality. Praise should also be given to "Lowestoft Harbour," by Reginald Craigie; "Portrait," by R. Dührkoop, a handsome girl at half length, designed and set upon the paper in the way of an old master; an exquisite profile, "Study of a Head," by C. J. von Dühren; another "Study of a Head" of quite opposite beauty, by S. Fischer-Schneevoigt; "St. Viglio," by T. and O. Hofmeister, a romantic Italian villa; "The Letter," two early Victorian ladies by Mrs. Käsebie; "The Pianist," by Guido Rey; "Mother and Child," by Eva Watson Schütze; and "Notre Dame," by W. O. Underwood. There are, of course, many others of established fame by workers well known to our readers which it is unnecessary that we should refer to here.

## Analecta.

Extracts from our English weekly and monthly contemporaries.

### The Combined Bath.

A formula that I have employed for several years with very satisfactory results (writes Mr. H. W. Bennett, in "The Amateur Photographer and Photographic News," of August 25) is the following:

Hypo .....	2 oz.
*Ammonium sulphocyanide .....	20 gr.
*Lead acetate .....	10 gr.
*Gold chloride .....	1 gr.
Ammonia .880 .....	10 mm.
Water to make .....	10 oz.

The hypo should be mixed with sufficient water to make 10 oz., and the other ingredients added in the order given, the solution being stirred or shaken between each addition.

This formula gives warm tones. For warm purple one-fourth of each ingredient marked \* should be used. For deep purple quantities should be 30 gr., 15 gr., and 1½ gr. respectively, the quantity of water and the amounts of the other ingredients remaining unchanged. Ten ounces of solution will be sufficient for eight whole plates, fifteen half-plates, or thirty-two quarter-plate prints. A smaller number proportionate quantities should be taken.

The prints are immersed in the solution without any preliminary washing. They should remain in the solution for twelve minutes at the least, the amount of gold being regulated so that the desired tone is not produced in less than that time. This is the reason for varying the quantities of some of the constituents.

The most simple and satisfactory method of preparing this is by keeping a series of stock solutions.

No. 1.—Hypo .....	16 oz.
Water sufficient to make .....	32 oz.
No. 2.—Ammonium sulphocyanide .....	2 oz.
Water to make .....	11½ oz.
No. 3.—Lead acetate .....	1 oz.
Hot water to make .....	11½ oz.
No. 4.—Gold chloride .....	15 gr.
Water to make .....	3½ oz.
No. 5.—Ammonia .880 .....	1 oz.
Water to make .....	12 oz.

For preparing the bath from these stock solutions, for warm tones take:—

No. 1 .....	4 oz.
Add water .....	5 oz.
Nos. 2, 3, 4, and 5 .....	each 120 mm.

### Hypo-Alum Toning of P.O.P.

My method of procedure (writes a reader of "Photography Focus" of August 25) is as follows:—First, I print slightly denser than the finished print is required to be. Then I place it straight in hypo without any previous washing. Three ounces of hypo to a pint of water, for ten minutes—no longer. Then I transfer it, without washing, to the following hypo-alum bath:—

Hypo .....	3 oz.
Alum .....	1 dr.
Water to .....	20 oz.

It is left in this until the tone that is desired is acquired, finally, is washed for an hour, preferably by suspension.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, AUGUST 29.

Aberdeen Photo Art Club. Outing to Kennay.  
Southend-on-Sea Photographic Society. Outing to Childeritch.

SUNDAY, AUGUST 30.

United Stereoscopic Society. Outing to Epping Forest.

TUESDAY, SEPTEMBER 1.

United Stereoscopic Society. "Some Stereoscopic Curiosities." F. Low.

WEDNESDAY, SEPTEMBER

North Middlesex Photographic Society. Lantern Slide Competitions.

## New Apparatus, &c.

"Bronzine" Photograph Frame. Sold by John J. Griffin and Sons, Ltd., Kingsway, London, W.C.

novelty in the shape of a metal photograph frame at a very moderate price has been introduced by Messrs. Griffin under the above name. The frame has the effect of a hammered partly polished metal, and may be used for almost any description of

photograph. The price for a cabinet frame of outside size  $9\frac{1}{2}$  in. by 7 $\frac{1}{2}$  in. is 1s., whilst an 8 $\frac{1}{2}$  in. by 6 $\frac{1}{2}$  in. frame with opening for standard size sells at 9d. In addition the same design is obtainable for two midget photographs, 1 $\frac{1}{8}$  in. by 1 in., at 3s. per dozen. Each case the above price is for the frames complete with glass. A line of frames which should repay the attention of both dealers and photographers.

## New Materials, &c.

ALBUMS.—Messrs. Griffin, of Kingsway, London, W.C., send a specimen of an album for quarter-plate prints just issued by them at the very moderate price of 1s. The album measures outside  $9\frac{1}{2}$  in. by 6 $\frac{1}{2}$  in., and contains space on each page for two quarter-plate prints, the pages being made up in a selection of art

designs, all of almost neutral colour. A pleasing variation is made in the shape of the openings, and the album accommodates altogether 32 prints. For keeping together prints of a particular series one of these most inexpensive albums should be very convenient.

THE LATE MR. BENJAMIN WYLES.—The death took place, at King's Norton, Birmingham, last week, of Mr. Benjamin Wyles. The deceased was well known in the town, where for many years he carried on a photographic business.

## CATALOGUES AND TRADE NOTICES.

CAMERA BELLOWS.—The catalogue of H. G. Glanville, 256, Balsall Heath Road, Birmingham, is sent to us and is found to list the variety of bellows, lens and camera cases, and other cloth and leather photographic goods manufactured by this firm. The list is sent free to the trade.

ALTRINCHAM SPECIALITIES.—A new list has been issued by the Altrincham Rubber Co. describing their latest photographic specialties in the way of camera cases, backgrounds, squeegee pads, etc.

ROSS LENSES AND CAMERAS.—A new 1908 list, just issued by Messrs. Ross, Ltd., 111, New Bond Street, W. consists of a handsome volume, which fully specifies the apparatus made by this ancient firm or sold under its recommendation. The "Homocentric" and other notable "Ross" lenses figure in its pages, but Messrs. Ross also make the Zeiss lenses. The best of hand and stand cameras are described, and one of the most useful purposes which such a list serves is the selection which it makes of apparatus which may be unhesitatingly commended to the purchaser requiring a good article. In one or two items the list "intelligently anticipates"; for example, it describes the forthcoming Thornton-Pickard universal front reflex camera. Altogether a most valuable guide to reputable photographic apparatus, and worth the shilling which is charged for it. An abridged list describing rather more popularly priced apparatus is sent free.

## Commercial & Legal Intelligence.

A SCARBOROUGH BANKRUPTCY.—At the offices of the Official Receiver, Scarborough, on August 20, the first meeting of creditors was held in the case of Joseph Edmund Bramwell, a photographer, residing at 38, Beechville Avenue, and lately carrying on business at 124, Westborough, Scarborough. Debtor's statement of affairs showed gross liabilities amounting to £289 6s. 10d., all of which is expected to rank for dividend. The assets amount to £15 5s. 11d., leaving a deficiency of £274 0s. 11d. Debtor attributes his failure to bad trade, owing to severe competition and bad seasons, pointing out that eight photographic establishments have opened at Scarborough since he commenced business.

LEGAL NOTICES.—A receiving order was made in Warwick Bankruptcy Court last week against Joseph Harris, residing at 10, Chapel Street, and carrying on business at 15, High Street, Warwick, photographer.

DISSOLUTIONS OF PARTNERSHIP.—The partnership between Messrs. Geo. Hy. Hutton-Preston and Percie L. D. Moulton, carrying on business as photographers and miniature painters at High Street, Broadstairs, Kent, under the style of Hutton-Preston and Co., has been dissolved, by mutual consent, as from August 11.

The partnership between Messrs. Geo. Liley and Hy. Arthur Penfold, carrying on business as photo-apparatus and material dealers, etc., late at 522, Stratford Road, Sparkhill, Birmingham, and now at 73, Wordsworth Road, Small Heath, Birmingham, under the style of Liley and Penfold, has also been dissolved, by mutual consent, as from July 11.

## NEW COMPANIES.

A. S. PRICE AND CO., LTD.—Capital, £2,000, in £1 shares (1,000 Pref.). Objects: To acquire the business carried on at Blackheath, Staffs, as A. S. Price and Co.; to adopt an agreement with J. H. Price, and to carry on the business of chemists, druggists, dyers, oil and colourmen. Dealers in photographic and scientific apparatus, etc. Private company. The first directors (to number not less than three nor more than five) are: J. H. Price, A. S. Price, and J. H. Price, jun. (all permanent; special qualification, 100 ordinary shares). Qualification of ordinary directors, 50 ordinary shares. Registered office, 181, High Street, Blackheath, Staffs.

KOSMOS PHOTOGRAPHICS, LTD.—Registered August 18, by Christopher and Roney, 33, Cornhill, E.C. Capital, £5,000, in 4,500 Preferred Ordinary shares of £1 each and 10,000 Deferred Ordinary shares of 1s. each. Objects: To carry on the business of photographers, photographic printers, chemists, manufacturers of photographic requisites, etc. Private company. Table "A" mainly applies.

## News and Notes.

**DAY TOURS IN BEAUTIFUL ENGLAND.**—The newly instituted day circular tours of the Great Western Railway Company represent a piece of railway enterprise which photographers of all people should be quick to appreciate. The preliminary run round a district is always an advisable thing before taking a holiday, and when the holiday-maker can be taken from London to Herefordshire and back and given ample time to visit Hereford, Gloucester and Worcester in the day, all for the sum of 7s., the expense of this first look round becomes insignificant. Last week we mentioned two similar series of day circular tours to Warwickshire and the Wye Valley respectively. The present offer is even more attractive, and application for the full prospectus obtainable from the Enquiry Office, Paddington Station, may be recommended. Some particulars of the ways in which the day may be spent will be found in our advertising columns.

**BURGLARY AT "N. AND G.'S."**—A serious burglary took place at the premises of Messrs. Newman and Guardia, Ltd., 90 and 92, Shaftesbury Avenue, W., between Saturday night and Monday morning. The burglars appear to have entered the premises through a flight facing Macclesfield Street, being one side of the premises turning out of Shaftesbury Avenue. The haul consisted of the smaller description of cameras manufactured by Newman and Guardia, and the chief interest seems to have been in securing a large number of the new "Sibyl" pocket cameras, which have only recently been put on the market. No doubt cracksmen of the first order had something to do with this, as a very excellent jemmy was discovered, also one glove, evidently used to prevent detection by finger marks. A rather interesting feature of the case was the use of a duster on the top of steps which were used to leave the premises. This, no doubt, was to prevent the possibility of foot marks being traced. The following is a rough list of the goods taken:—

One 4-pl. S.R. Reflex camera, No. 2,051, fitted with Zeiss "Double Protar" lens, No. 101,704-101-701, with 1 dark slide, changing box, No. 4,423, pneumatic release attachment, and leather case.

One 4-pl. S.R. Reflex camera, No. 1,949, fitted with Zeiss "Double Protar" lens, No. 83,225-83,232, with 1 dark slide, holder for auto-chrome screen, and leather case.

One 4-pl. "Nydia" camera, No. 887, with changing box, No. 1,106, fitted with Ross "Homocentric" lens, No. 63,543, with lens cap, and level on box, and leather case.

One front only of a 4-pl. special B camera, No. 1,310, fitted with Zeiss "Double Protar" 3-foci lens, No. 44,714-44,428.

One 4-pl. "Sibyl" camera, No. 278, fitted with Zeiss "Tessar" lens, No. 103,383; one 4-pl. "Sibyl" camera, No. 282, fitted with Zeiss "Tessar" lens, No. 103,387; one 4-pl. "Sibyl" camera, No. 283, fitted with Zeiss "Tessar" lens, No. 103,388; one 4-pl. "Sibyl" camera, No. 284, fitted with Zeiss "Tessar" lens, No. 103,369, with one dark slide, velveted inside back, and focussing screen, with collapsible hood; focussing screen of this camera is specially marked down to 1½ yards.

One 3½in. x 2½in. "Sibyl" camera, No. 213, fitted with Cooke lens, No. 18,688; one 3½in. x 2½in. "Sibyl" camera, No. 273, fitted with Cooke lens, No. 19,496; one 3½in. x 2½in. "Sibyl" camera, No. 274, fitted with "Cooke" lens, No. 19,497; one 3½in. x 2½in. "Sibyl" camera, No. 275, fitted with "Cooke" lens, No. 19,498; one 3½in. x 2½in. "Sibyl" camera, No. 276, fitted with "Cooke" lens, No. 19,499; one 3½in. x 2½in. "Sibyl" camera, No. 277, fitted with "Cooke" lens, No. 19,500.

One 3½in. by 2½in. "Sibyl" camera, No. 209, fitted with Zeiss "Tessar" lens, No. 91,711; one 3½in. x 2½in. "Sibyl" camera, No. 253, fitted with Zeiss "Tessar" lens, No. 104,250.

One Zeiss, Series II. B "Tessar" No. 8 lens, 12in. focus, f/6.3, No. 85,943.

One 5 x 4 Wizard camera, triple extension, fitted with 3-foci rectilinear lens and automatic shutter, with 6 double dark slides and leather case.

One "Suter" rectilinear lens, 10in. focus, f/5.6, No. 11,685; one "Suter" rectilinear lens, 6in. focus, f/5.6, No. 9,855.

One large leather case for six 15 x 12 double dark slides.

Three panel fronts for 15 x 12 "Hare" camera.

One large leather case for 12 x 10 "Dallmeyer" camera.

One tripod top.

### CHANGING BOXES.

Four 4-pl. "N. and G." changing boxes, pattern A, Nos. 4,382, 4,383, 4,385, 4,405.

Three 4-pl. "N. and G." changing boxes, pattern B, Nos. 3,931, 3,933.

Two 5 x 4 "N. and G." changing boxes, pattern A, Nos. 4,413.

One 5 x 4 "N. and G." changing box, pattern B, No. 4,183.

Six 4-pl. "N. and G." Reflex changing boxes, Nos. 4,436, 4,494, 4,495, 4,496, 4,497.

Two 5 x 4 "N. and G." Reflex changing boxes, Nos. 4,429,

24 4-pl. "N. and G." "Nydia" changing boxes, Nos. 1,270, 1,272, 1,286, 1,290, 1,294, 1,295, 1,296, 1,297, 1,298, 1,299, 1,301, 1,302, 1,303, 1,326, 1,327, 1,372, 1,387, 1,388, 1,389, 1,391, 1,392.

15 4-pl. "N. and G." "Nydia" changing boxes, with Ru leather bellows, Nos. 1,070, 1,071, 1,187, 1,375, 1,376, 1,377, 1,379, 1,380, 1,381, 1,382, 1,383, 1,384, 1,385, 1,386.

9 9 x 12 c/m "N. and G." "Nydia" changing boxes, Nos. (with level), 994, 995, 996, 997, 998, 1,042, 1,043, 1,044.

2 5 x 4 "N. and G." "Nydia" changing boxes, Nos. 1,274, 1,275.

3 3½in. x 2½in. "Sibyl" changing boxes, Nos. 4,453, 4,458, 4,459.

The most regrettable part of this burglary is that the thieves should have selected "Sibyl" cameras, the stock having only just been completed, and the demand for this particular "N. and G." model being in excess of production. Great disorder prevailed in the private office on the first floor when the clerks entered Monday morning, but strangely enough no damage was done to any of the delicate apparatus thrown about on the floor.

## Correspondence.

### STEREOSCOPIC PORTRAITS.

To the Editors.

Gentlemen,—In regard to the abstract of our recent patent we may be allowed to point out that the process is intended to be used in the production of a stereoscope and slides of the sitters' portraits for a nominal sum, in other words the popularising the once familiar form of stereoscopy. We enclose our "Mirror," which "serves a double debt to pay"—a stereoscope unfolded, and a pocket case for the slides when closed. The rapidity and accuracy and reliability of the process enables us to produce stereoscopic portraits of our sitters, ready the following day, and we believe we are the only firm producing stereoscopic portraits on a commercial basis (that is to our knowledge, and in the ordinary manner of the studio as cabinets are produced).

From the commercial point of view and also that of an educational one, our process is unequalled for precision and attractiveness, as a means of advertising and bringing details to the public mind—things that might otherwise pass unnoticed when depicted in the ordinary photograph.—Yours faithfully,

9, Mary Street, Dublin.

THE DYAS PHOTOGRAPHIC CO.

### THE R.P.S. FELLOWSHIP FOR HON. SECS.

To the Editors.

Gentlemen,—I notice you have a paragraph this week, under the heading "Ex Cathedra," referring to the granting of Fellowship by the R.P.S. to the hon. sec. of long standing and energy. I do not know if you would care for the question to be discussed in your correspondence columns. If so, perhaps you will kindly publish the letter. I may say that I quite agree with the suggestion which has been made. One of the qualifications for the Fellowship is that the candidate shall have made some considerable contribution to the dissemination of photography. I maintain, Sirs, that a really capable secretary fulfils this condition. I even think he is more deserving of the honour than the man who gets it for his skill in the practice of photography. This is heresy, perhaps, but I believe it to be correct. Why? Because a photographic society is established for the advancement of photography, and the man who keeps it up to this ideal for ten years, with, oftentimes, very small thanks, is, in my mind, deserving of this official recognition. The fact that he may not be a member of the R.P.S. is surely easily disposed of by his becoming one. I think this suggestion to be worthy of serious consideration, and trust that the end desired will some day be reached.—Faithfully yours,

LEWIS LLOYD,

Church Road, Moseley.

Hon. Sec. M.P.F.

August 22, 1908.

## Answers to Correspondents.

**Letters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C."** Inattention to this ensures delay.

**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.**

**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., Wellington Street, Strand, London, W.C.**

**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street Strand, W.C., undertake the registration of copyright photographs at a charge of 7d. each photograph, to cover cost of registration fee, form, etc. Unmounted copies of each photograph must be sent with the**

### PHOTOGRAPHS REGISTERED:—

**We do not know anything of the character of the firm. You must remit to them by foreign money order from any post-office.**

**G.—We do not know who now supplies them. MESSRS. L. P. and Co., Milton House, Chiswell Street, London, E.C., supply a very similar article.**

**Cleethorpes).—Write Dorrett and Martin, 16, Belle Vue Road, Tooting, S.W.**

**QUERIES.—(1) Will you please compare for me the merits of spirit sensitising with spirit sensitising for carbon? I have noted head note to an article on the former, in July 3 issue and here, where it was claimed that good detail in the high-lights was obtained. (2) What bearing on gelatine in carbon have your notes on permanency of photographic records in July 17 issue? (3) What objections are there to making negative through the glass to obviate double transfer in carbon works? Would thin films be flat enough for good work with wide open lenses if used for the same reason? — H. W. GAULD (to be).**

**The spirit sensitiser is the more convenient to use, as the dries in about a quarter of an hour, whereas with the other takes some hours. Tissue sensitised with the citric solution is suited for thin and flat negatives, but with those of a vigorous character, such as are usually employed for carbon, there is a necessity for the more delicate tints in the lights to wash away. Citric tissue is much slower in printing than that sensitised with spirit sensitiser. (2) There is no risk of carbon prints changing in any way that the unvarnished negatives did. (3) None whatever, provided that the back is made quite clean and the glass is free from air bubbles. (4) Yes, if the films are strained thoroughly flat in the roll-holder.**

**REDA.—Will you kindly inform me whether the "Encyclopedia of Practical Photography," mentioned in the "B.J.," August 18, re Hollinger lighting, may be obtained in England? If so, where and price?—C. A. B.**

**As far as we know it is not at present obtainable, but you had better apply to Messrs. Dawbarn and Ward, 6, Farringdon Avenue, London, E.C.**

**ERS.—Can you tell me in a simple manner the actual advantage of a lens at  $f/6.8$  to one at  $f/8$ —that is, how much exposure will  $f/6.8$  require than  $f/8$ ? I should imagine that for a certain subject 1 sec., then  $f/6.8$  would want about 1.5 sec.**

**is right almost exactly. The exact ratio is 46:64, which, for practical purposes, is 3:4.**

**NE FOR ENLARGING.—Is it practical to use an acetylene lamp in an enlarging lantern? How would the light compare with incandescent gas?—J. H. L.**

**You can use an acetylene light, but for smallish work up to 12 or so, it is not so convenient as incandescent gas. It is on the candle power of the lamp.**

**AUTOCHROME EXPOSURES.—Will you in your "Answers to Correspondents" kindly reply to the following:—1. In taking an Autochrome of a stained glass window, how should the meter be used in order to ascertain the correct exposure? Should it be held toward the light outside the window in order to obtain the intensity of light passing through high-lights, or inside, from where the camera is erected, which, I suppose, would give the intensity of the light reaching the plate? 2. What would be the speed number of plate in such a case?—G. A. H.**

**1. For work of this nature we should use Watkins' special Autochrome dial, and hold the meter inside the window and facing it. 2. The speed should be taken as 1 Watkins. If you do not use the special meter you will probably find much trouble in hitting the right exposure. With a large aperture and ordinary meter the exposure will probably be two or three times the amount indicated.**

**P. P. AGENCY.—Of course the work is of the lowest class, but the prices offered by the firm surely indicate the class of its output. You have a legitimate grievance as regards the breakage of the negative, if the people were negligent in packing it for return.**

**S. F. D.—You should serve for the full period, whether paid this week or not, and you can then recover the two weeks' wages in the County Court.**

**A. W. B.—If you send full particulars of your lens to Messrs. Dallmeyer no doubt they will be able to supply you with an attachment to fit it. For our own part we should let them have the lens so as to be quite sure that everything is in perfect adjustment. Your lens is very long focus for telephoto work, and would require a proportionately long focus negative. The cost would probably be £5 or £6 or more. Whether you have high power or moderate power depends on what you wish to do. Moderate power is most serviceable generally.**

**METOL STAINS.—I have my hands constantly in metol, bromide developer, and through this they have become very black. Can you tell me how to remove these stains?—BROMIDE.**

**We never heard of such stains caused by metol, and if your hands have arrived at the stage of blackness it is a wonder you have not suffered from metol poisoning. We do not know any certain quick way of removing such stains, but they will probably disappear if you keep your hands out of the developer and wash frequently in hot water for a few days.**

**LENS FOR SHORT STUDIO.—May I ask you to kindly advise me as to the most suitable lens for full length cabinet work in an 18ft. studio? Having rather a poor light I desire a lens working at large aperture. To secure good definition with my present one I must stop down to  $f/8$  or smaller. This, as you will believe, is very inconvenient at times. Any particulars you can give, including prices, would greatly oblige.—STUDIO.**

**The studio is very short for taking full length cabinets in with a lens working with a large aperture. A lens of 9in. focus will require about 13ft. between the camera and the sitter, and that will only give you 5ft. for background, sitter, accessories, etc., and for the camera. Therefore we should advise you to obtain a lens of the anastigmatic type, having an aperture of  $f/4$  or  $f/4.5$ , such as the stigmatic of Dallmeyer, the Ross-Zeiss Tessar, Voigtlander Heliar or the like. All of these will answer your purpose, as they cover well, and have a flat field.**

**PRINTING HOUSE.—I am about to erect a wood house, chiefly for P.O.P. postcard printing. I should like same to be parallel with the garden walls, as it would look better. 1. On which side, A, B, C, or D, would you face the house—that is, the glass front? 2. I thought of putting glass from within 3ft. of the floor. Would you recommend other dimensions? 3. I thought of having glass along the bottom half of roof, as shown in sketch. Would you recommend other dimensions? 4. Which would be best, to have plain or frosted glass on roof? 5. Would it be best to have table made flat or inclined, as shown in sketch, for placing printing frames on?—J. V. THOMAS.**

**1. The glass should be on side D to secure the north light. 2. For printing purposes we do not see that the height is of much importance, but we should keep sill well down so as to make it easy to reach the frames. 3. A good deal depends on whether you have uninterrupted north light through side windows. If not, a roof light will be necessary, one about the width of the table.**

4. Plain glass. Frosted glass will cut down the light too much. In any case printing through glass is slower than in the open, so we should arrange for printing outside in fine weather, or else make the windows to open. 5. A table of adjustable inclination would be best. For actual printing, a good slope that will bring the frames near the window is advisable. If a good vertical north light is available we should prefer to fit the window itself with racks that hold the frames close to the glass. A flat shelf could be used in fine weather, and shelving under the top light could be used indoors.

**RENOVATION OF CAMERA.**—A little while ago, my studio camera looking shabby, I polished it up with a furniture polish, as used by the household. I used it exactly as the directions said, and thoroughly dusted it before the polish was applied. When finished it had a good polish, but it really looks worse than it did before. The flat parts are all right, but the corners are dark, and have a black look which the bright polish seems to have made more noticeable than they were before. Can you suggest anything that I can do, as the camera looks very bad as it is.—A. J. COXE.

What you have evidently done has been to apply the polish without previously removing the dirt from the corners and, as a consequence, you have polished the dirt, and thereby made it more conspicuous than it was at first. All that can be done now is to remove the polish, thoroughly wash off the dirt with warm soap and water, and apply fresh polish. As we do not know the composition of the polish you have used, we cannot suggest the best way of getting it off.

**COPYRIGHT.**—One town council have in their possession a number of very old manuscripts, maps, etc., relating to the district. I have thought of copying them and publishing them as postcards. That I can get permission to do, and, moreover, the authorities will give me every facility for doing the work. What I want to know is this: If I make the copies copyright, will that prevent anyone else from copying them?—VILLAGER.

If you make your copies copyright, that will protect them from infringement. But you must understand that it will not prevent anyone else from making similar copies from the originals, if they get permission from the council to do so. Copyright in your reproductions will not apply to the originals.

**LENS QUERY.**—I have a 12 by 10 R.R. lens, which seems to be a very good one, and it ought to be, as I paid a good price for it. But I find that when I focus with the full aperture and then stop it down to get all parts in focus the negatives are not so generally sharp as they ought to be. The other day, when the light was very bright, I focussed a picture very sharp and then stopped the lens down to  $f/32$ . I then found that some parts of the picture were not really so sharp as they were with the full aperture. Can you account for that?—THOS. WILSON.

The lens you have has a certain amount of spherical aberration, as most lenses of this type have—more or less. In future, focus the image with a medium size stop, say,  $f/16$ , and then stop down still further to get all planes sharply defined. In this way you will get all parts of the negatives sharp—that is assuming that the instrument is a reasonably good one.

**F. B.**—No such paper as you describe is obtainable commercially. We should not take at all a sanguine view of the demand for such a material.

**POSTCARD.**—Certainly you need not. You can draw up the licence to the effect that the reproductions are to be as postcards only. You will then be free to grant the reproduction of the photograph in any other ways.

**M. E. N.**—A paint which has been recommended for a flexible lantern screen is made as follows:—Glycerine, 1 lb.; white glue, 1 lb.; zinc oxide, 2 lbs.; hot water, 1 gallon. This is applied hot to the screen, using about 1 gallon for a screen 10 ft. square.

**REDUCING SULPHIDE-TONED BROMIDES.**—Is there any means of bringing down density of an enlargement (bromide) which has been sepia toned with the ferricyanide and sulphide solutions? I ask because in my absence an assistant toned a 30 by 20 enlargement without first letting me see it when I should have lightened it a little. Therefore, if you can reply in Friday's "Journal" I shall be grateful.—MAX COHEN.

Prepare a mixture of equal parts of 5 per cent. copper chloride solution and 15 per cent. salt (sodium chloride) solution. This

forms a suitable solution. The print is washed for about minutes and fixed in hypo for a minute or two, and finally washed.

**G. HERON.**—The device is not new. A precisely similar suggestion was made in our own columns about a year ago by Mr.cliffe, of Whitby. See "B.J.," June 28, 1907, p. 494.

**TREACLE DEVELOPER.**—Some months ago you gave a formula for a developer in which treacle was contained. It was for plates where fog was likely to occur, and though I did not make a note of it, but have since been unable to find either it or the article in the back numbers of the "Journal." Can you please indicate the date of publication and oblige.—ESTIMATION.

We have no recollection of such an article in our pages, but think you most probably refer to a formula of Mr. R. H. B. which appeared in "Photography," for August 27 of last year. The formula ran:—

Metal	50 grs.
Hydroquinone	40 grs.
Soda sulphite	14 ozs.
Washing soda	14 ozs.
Potass bromide	20 grs.
Water (boiled)	20 ozs.

Half an ounce of this developer and two large teaspoonfuls of golden syrup mixed with 10 ozs. of water formed the developer.

**DENSE TRANSPARENCIES.**—I want to make some very dense transparencies from some rather thin negatives. I have tried to get them on slow plates but cannot get what I want. When I increase the density I require there is a veil over the transparent parts, and for these quite bare glass is necessary for my purpose. A friend suggested that I should employ the carbon process and the special transparency tissue. That I have done, and although I get the transparent parts clear glass the others are not so clear enough. Can you help me out of my difficulty, as the transparencies seem to meet my requirements if I could get them denser?—T. R. WANT.

Instead of using the special transparency tissue, which contains a large amount of pigment in proportion to the gelatine, we advise you to try one that contains less, such as, we will suppose, portrait brown or purple. With such tissues the light penetrates deeply into them, and as a consequence the picture has a considerable amount of relief in the shadows when developed. To intensify the transparency with a solution of permanganate and potash—strength immaterial. The reason why in this case it is better to employ a tissue thin of pigment (that gives a thin film of gelatine) is that it is the gelatine only that is acted upon by the permanganate, and not the pigment itself. Consequently, a thick film of gelatine almost any degree of density may be obtained, while the light remains as clear glass.

**J. C. V.**—A portrait lens of six inches back focus is not suited for taking groups of several persons on the cabin picture. That fully accounts for the indistinctness of the figures in the print sent. You require a longer focus lens for pictures, and one with a flatter field, as we notice that the figure of the centre standing figure is not in the same focus as the figure of the body.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

New Method in Time Development.—Professor G. H. Bryan has a direct method of employing the time method in development by first testing the activity of the developer. Mr. Alfred Mees, comparing the method with his already known test-slipure, considers that Professor Bryan's modification is an improvement. (P. 677.)

"B.J. Almanac."—The attention of secretaries of photographic societies is invited to applications for particulars of these which will shortly reach them.

Editorial notes on the different types of actinometer which are used for carbon and other forms of printing processes which give a visible image appear on page 675.

S. E. Sheppard has communicated to the Royal Photographic Society the results of tests on the best conditions for colour sensitising with the iso-cyanine dyes. (P. 678.)

New description of reflex camera is among the patents of the month. (P. 682.)

Practical methods to be followed in using a lens with a fixed focus appear on page 676.

## "COLOUR PHOTOGRAPHY" SUPPLEMENT.

Lecture on the Thames, illustrated with Autochrome plates, will be a feature on three nights of each week at the R.P.S. Lecture, which opens at the New Gallery on Thursday week. We publish an interview with the lecturer and maker of the slides, Mr. McIntosh. (P. 65.)

Newer Screen-plates.—We describe a modified form of the Dr. Powrie screen-plate. Specimens of the work of the "New" screen-plates were exhibited in London last week. (P. 68.)

"Uto" Bleach-out Process.—Dr. J. H. Smith announces experiments in various directions in the manufacture of the "Uto" process. (P. 68.)

F. C. Tilney, in reviewing the reproductions of Autochromes in "Studio" summer number, emphasises the special importance of selection and composition at the time the exposure is made. (P. 69.)

E. Stenger and Herr F. Leiber have published a paper showing the mechanism of the preparation of copies of one screen-plate transparency from another. Their results confirm those of Dr. Mees, and, in the "Colour Photography" Supplement, drew attention to this matter. (P. 69.)

## EX CATHEDRA.

### The "British Journal Almanac," 1909.

The issue of the "B.J. Almanac" for next year is already the object of our care, and the next few weeks will see a large proportion of its matter set up in type. Our efforts of late years have been devoted to the systematic arrangement of the contents of the "Almanac," and the forthcoming issue will witness a further notable departure in this direction which will, we believe, be appreciated. Within the next few days we shall apply to secretaries of photographic societies for certain particulars to be inserted in the directory of these bodies. These applications are addressed in most cases to the secretaries whose names appear in last year's list, but as in some instances there have been changes which have not been brought to our notice, we would ask that the form may be at once forwarded to the person at present holding office.

\* \* \*

### Society Programmes.

The winter session of many photographic societies being now on the point of commencing, we may remind our good friends the secretaries that fixture lists may be sent to us for announcement of the programme week by week in our "Societies" column. We fear that comparatively few photographic societies are in a position to issue a fixture list of the length and interest of that, say, just completed by the Liverpool Amateur Photographic Association, which has set before its members what is to be offered them up to April 15 of next year. But, then, few societies have an Inston at the helm to provide the mixture of popular and technical fixtures which, in these days of simplified photography, appears to be more acceptable than the evenings of formulae and such recondite themes which attracted photographic clubmen of ten years ago.

\* \* \*

### Gaslight and Bromide Images.

A writer in a contemporary makes some rather rash statements with regard to the comparative toning properties of gaslight and bromide papers. He states that the composition of the image on a bromide print and on a gaslight print, when both come out of the fixing bath, is the same, and therefore all toning processes that are employed after fixing may be used indiscriminately either for gaslight or bromide papers. According to this writer the image after fixing consists "simply of metallic silver embedded in gelatine," and while he states that the silver in the gaslight paper may be of finer grain than that in the bromide paper, he gives no proof of this any more than he does of the other statement. Possibly his experiences have been confined to the varieties of gaslight papers that are nothing more than very slow bromides. These do tone in the same way as the ordinary bromides, but chloro-bromide emulsions

behave very differently, and few, if any, will yield good results with sulphide toning methods. It has several times been shown that these prints contain very little silver in the metallic form, and that the bulk of the image is made up by some compound. If we make two lantern slides, one on a bromide plate and the other on a chloride gaslight plate such as the Kristal, we may obtain equal density on each; but if both plates are put into persulphate, the silver on the bromide plate is slowly removed until little trace of the image remains, while the black silver on the other plate rapidly disappears, leaving a strong brown image behind. Further than this, the one image can be intensified by simple redevelopment, while the other cannot. These tests afford ample proof that the images are not the same, and also suggest reasons why they tone differently.

### The Correction of Distortion.

The interesting article on this subject by Mr. Debenham in last week's issue points out very clearly the errors that many fall into when attempting to correct convergent distortion. Time after time we see it stated in text-books and elsewhere that the required connection can be easily obtained by saving either the negative or the copy, yet it has long been known that this only corrects the uprights at the expense of distorting the heights, and that the result is far less correct than was the original "distorted" image. Mr. Debenham does not give any definite rules for effecting the true correction, but a very simple method is given in the "Almanac" for 1908, page 950. In this method the original lens is used, and all the data required are found very quickly and easily from the distorted negative itself. This subject of correction is a very interesting but somewhat complex one, especially when the matters of securing perfect correction and good focus at a large aperture are combined. A full investigation of the subject by Mr. C. Welborne Piper was published in "Camera Obscura" for March, May and June, 1900, and from this it will be seen that the conditions are curiously inelastic when the question of focus is included. Enlarging and the use of a long focus lens then becomes essential, and reduction or copying full size is entirely prohibited. If, however, we rely on a small stop for focus then reduction and the use of the original lens becomes possible. A method for reduction is given in the "Almanac," but for preference we recommend the first enlarging method given, which gives quite accurate results at a fairly large aperture. If a reduced or full size copy is required it should be made by reduction from the corrected enlargement. When we want an enlarged corrected negative we first make a positive by

contact from the original and produce the corrected negative from that. If a small corrected negative is wanted make an enlarged corrected positive and then a reduced negative from it. The process is quite a simple one and troublesome calculations are required.

\* \* \*

### Dührkoop's Quarter-Century of Photography.

Those who met Herr Rudolf Dührkoop at the Brussels Convention and during his subsequent short stay in London perhaps have found it difficult to believe that his twenty-five years in professional photography were prefaced by an almost equal period of ordinary commercial occupation. Yet Dührkoop returned from the Salon of Paris to enter business life, and it was not until twenty years later that he embarked upon the career of a professional photographer. And it was fifteen years later before he perceived his "métier" in the way of a powerful and characteristic portraiture. His whole and twenty years of photography will be celebrated in a characteristic German fashion by a "festmahl" on October 1st in the magnificent "Hamburger Hof" on the upper storey of which Herr Dührkoop's studios are arranged. We are pretty safe in anticipating that on that occasion the youngest of the company will be the host himself, despite his sixty-five years.

\* \* \*

### Keeping Properties of Carbon Tissue.

Mr. Harold Holcroft draws attention to the "A.P. and P.N." to an instance of unsensitised carbon tissue becoming soluble as the result of keeping for a period of from ten to fifteen years. Gelatine is apt to change its character as the result of long keeping, and every photographer is familiar with the fact that old negatives and prints often will not yield to various methods of after-treatment that succeed easily on fresh films. For example, a very old bromide print often cannot be used for the bromoil process, and the intensification of an old negative is frequently a risky operation. Carbon tissue may be reasonably expected to be affected in a similar fashion, while it is not at all unlikely that the pigments incorporated with it help to produce a change. Pigments of various kinds are used, and many pigments are metallic compounds extremely likely to themselves vary with the course of time and to affect the gelatine. Possibly hardened tissues referred to by Mr. Holcroft might have been rendered serviceable by adopting some treatment calculated to soften the gelatine, but we doubt very much if any treatment would have completely restored them.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1909.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-eighth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of over 1,000 pages, and the entire edition of 25,000 copies was sold out immediately. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1909 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

### REFLEX CAMERAS,

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1909 will be

modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1909 will appeal to photographers the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and, wherever practicable, features of an informative nature will be added.

**\*\* IMPORTANT NOTICE.**—The attention of advertisers specially directed to the announcement that the new edition of the ALMANAC (25,000 copies) will again be put in the hands of dealers and the trade on December 1st, as to be well in advance of the Christmas publishing season, and the co-operation of advertisers to that end will be esteemed by the publishers.

# SOME NOTES ON ACTINOMETERS.

The term "actinometer"—denoting an instrument for the measurement of the chemical activity of light—is used in photography in a very restricted sense. It is commonly understood to apply to one or other of the appliances used for gauging the power of the light when printing from negatives. An "exposure meter"—or at any rate that form of it which does really measure the light—is actually something more than an actinometer, but the two distinct terms have come to possess their separate applications in positive and negative photographic work. The construction of an actinometer is a matter on which perhaps a whole volume might be written, but the inquiry of a reader as to the most useful types of the instrument may be best answered here in the form of these notes, which may thus be of service to the increasing number who of late years have adopted carbon printing. The employment of some method of timing the exposure in this process is essential, seeing that the effect of the lights is not at once visible to the eye as it is in most other printing processes. Yet the use of an actinometer is also convenient in other processes, such as the gum-bichromate and platinotype, when a large amount of work is in hand, as well as in the exposure of collotype plates, etc.

The names of inventors of actinometers for carbon printing are legion, and amongst them may be mentioned Johnson, Vidal, Monckhoven, Lamy, Sawyer, Spencer, Barton, Hemagis, Vogel and others. The difference in construction and principle between some of the instruments is but slight; in some instances very slight indeed. They depend upon the changes that a sensitive paper undergoes on exposure to light. Various sensitisers for the paper were suggested many years ago, such as different salts of iron, chromium, and silver. But with the exception of the last two these ancient recommendations did not come to be at all generally applied in practice. Some twenty or more years ago different formulæ were published for preparing sensitive silver paper. The following is one given by M. Lamy. The paper he employed was plain thin paper (8 kilos) which was immersed for ten minutes in the following:—

Chloride of ammonium .....	2 gms.
Water .....	100 ccs.
When dry the paper was floated for four minutes on:—	
Distilled water .....	100 ccs.
Silver nitrate .....	12 gms.
Citric acid .....	6 gms.

The paper will keep good for several months.

Monckhoven employed a similar formula, but without citric acid; but after sensitising he washed out the free silver with water in order to make the paper keep after treatment, which it will do for a long time, though it is very slow in darkening. Most carbon printers at the present time employ the ordinary gelatine P.O.P. for the actinometer. Although silver paper is almost universally used for actinometers, theoretically it is not the right one for the purpose, for the reason that the sensitiveness of carbon tissue is subject to certain changes not followed by the silver paper; for example, temperature and its hygroscopic condition, as well as the time it has been kept in sensitising, have a marked effect on its sensitiveness, which is not correspondingly so in silvered paper, that is to say the two do not work in unison. In the attempt to imitate this Dr. Vogel recommended for his actinometer a paper sensitised with bichromate of potash, the bath being as under:—

Bichromate of potash .....	1 part.
Water .....	30 parts.

The paper, it was claimed, will keep for several weeks. But it is obvious that it, like all papers sensitised with bi-

chromate of potash, more or less slowly undergoes change. Some little while back we were in a large establishment on the Continent where several hundred carbon prints (mostly of large size) are turned out daily. The actinometer there in use was of quite a primitive kind. It was merely a small frame with a graduated screen with four or five steps. The sensitive paper used with it was the back of a piece of the carbon tissue then being worked, and it was claimed for this system that in the actinometer the sensitiveness of the paper backing was in accord with that of the pigmented coating on the front. Be that as it may, we were assured that the errors in exposure never exceeded 1 per cent. and rarely amounted to that.

It may, however, be taken that in general work under good conditions, the use of gelatine or collodion P.O.P. does not lead to any appreciable errors in timing the exposure of carbon tissue.

In regard to the actinometers themselves, it would be impossible in this article to deal with all the different forms which are given, as witness the Autotype Company's price list alone, which contains no less than five different kinds varying in price from one to six or seven shillings each.

Actinometers may be divided into two classes, those that depend upon a single tint for comparison, and those dependent upon a graduated scale of tints. A typical form of the former is that known as Johnson's—this was the invention of the late Mr. J. R. Johnson, so well known in connection with the carbon process. It is a little metal box about an inch and half square with a glass lid which is painted on the under side the same colour that silver paper assumes on exposure to light. In the centre the paint is removed to the extent of a quarter of an inch or so. Under the glass is a velvet pad which presses the paper in contact with the glass, whilst the lower portion contains a narrow band of silver paper. In the lid is a slot through which the paper can be drawn forward after exposure. In use the instrument is placed amongst the printing frames, and when the paper has darkened to the colour on the glass it is said to have been exposed, "one tint." The paper is then drawn forward and is then ready for another tint, and so on. A disadvantage of this form is that it requires constant watching, as if the tint be passed it is difficult to estimate how much it has passed it. Another drawback is that the silvered paper does not always take the same colour as that on the instrument, since the colour is dependent upon the paper's hygroscopic condition, though less so in the case of gelatine than with albumen paper.

The most generally useful actinometers for the carbon printer are those with a graduated numbered scale, several types of which exist. The "Woodbury" is one, though we think it is not now made commercially. It is a small circular box with a glass top which is divided into six sectors of different tints. In the centre is a small clear space, under which the paper is drawn through a slot in the side. The tints of the sectors correspond with the different tints that the paper assumes with different periods of exposure to light. A very simple scale screen may be made by taking a strip of thin paper, like bank post without water-mark, say 4 inches long and  $\frac{3}{4}$  inch wide, and on that securing at one end by gum another strip,  $\frac{1}{2}$  inch or less, and on that another still shorter than the previous one, and so on until we get a scale ranging from one to six or eight thicknesses of paper. These are then numbered. In use the scale is put into a quarter-plate printing frame, with a strip of P.O.P. behind, and we have an efficient actinometer as good as one can well desire. The Sawyer actinometer is similar to this; instead, however, of the paper scale, it is a carbon print on glass mounted in a convenient metal case, the under portion of which contains

a roll of sensitive paper which can be drawn under the scale. Burton's actinometer will appeal to many. In construction it is similar to Sawyer's, except that the screen is a series of tiny portraits of different densities, so that one may compare the density of the negatives to be printed from with one or other of them and expose accordingly.

In conclusion, the general advice may be given that when printing on a large scale, when one can be constantly watching the actinometer, the single tint ones may possibly be the best. But for general use, when other work has to receive attention at the same time, the scale form is decidedly to be preferred.

## CHEMICAL FOCUS IN LENSES AND HOW TO ALLOW FOR IT.

THE recent article, "Some Discursive Notes on Lenses," from the pen of Mr. H. M. Pelwith, has no doubt proved enlightening to many who have but a very limited knowledge of optics. In this article I may supplement by a few notes some misconceptions with regard to the class of lenses which possess a chemical focus—that is to say, a lens which, when the image is sharply focussed on the ground-glass, gives an unsharp image in the negative. When this arises it is sometimes attributed to the focussing-screen of the camera not being in accurate register with the dark slide, while in some instances it is really due to the lens itself. This is a point that is fully dealt with in all elementary treatises on optics, and need not be dwelt upon here, for it is sufficient to say that this quality existed in a very large proportion of the earlier portrait lenses. The same thing exists in a considerable number of the modern lenses which are fitted to some of the cheaper forms of fixed-focus hand-cameras. Although they are often sold as rectilinear—as, indeed they are—they really consist of two single non-achromatised glasses.

We know that some photographers of the present day would at once condemn a lens that did not work to focus as being unusable, yet the prejudice is based on a fallacy. All the earlier portrait lenses of Voigtländer—and they made his name famous amongst photographers—had a chemical focus, and when using them it was necessary, after focussing the image sharply, to rack the lens out a certain distance in order to obtain a sharp picture. The same thing obtains in most of the old foreign lenses, as they were mostly copies of Voigtländer's. At the period these lenses were made an instrument was sold at the photographic stores under the name of the "focimeter" for ascertaining the difference between the visual and actinic foci. It was an invention of the late M. A. Claudet, and consisted in segments of a circle, numbered, and placed at fixed distances apart on a movable axis. This was placed at some ten feet distance from the camera, the centre number being focussed upon and a photograph taken of it. After a mark had been made on the sliding-tube of the mount the figure that was sharpest in the picture was focussed upon, and the tube again marked at that point. The distance between the two marks showed the distance the lens had to be racked out to get the image sharp in the negative.

Most of Voigtländer's lenses had this distance engraved upon the mounts, but many of the copies of them had not—hence the use of the focimeter. When an old portrait lens is met with which has an engraved scale on the sliding portion of the mount, it may be taken for granted that the lens does not work to focus yet. As has just been said, although a lens may not work to focus, it need not be condemned for that reason. Voigtländer, it may be mentioned, when he first put focus-true lenses on the market, did so somewhat under protest, as he maintained that lenses over-corrected for colour gave better results, were quicker, and had more depth of focus than had those in which the two foci were coincident. Having said this much, we shall now explain how it can be simply ascertained if a lens has a chemical focus, and what is the difference between it and the visual one.

In the first place, it is necessary to be sure that the focussing-screen and the dark-slide of the camera are in accurate register for unless that is ensured the test may be misleading. There are different ways of making the test. One is to get a narrow strip of board, say three-quarters of an inch thick and an inch wide, and put a screw with a fine thread through it. The board is then placed across the focussing-screen and the screw turned until the point touches the glass so that it slightly grates upon the latter when the wood is moved about. A plate is then inserted into the dark-slide and the wooden bar passed over it. If the screw-point just touches the surface of the glass, as it did touch the focussing-screen, there is evidently accurate registration. Another plan is as follows:—A strip of cardboard is cut to a wedge-shape. A straight-edge is then placed across the focussing-screen—one of the dark-slides will do—and the wedge is pressed between it and the ground-glass. The wedge is then marked with pencil where it touches the straight-edge. The dark-slide, with a plate in it, is then dealt with in the same way: if it is found that the pencil-mark accurately cuts the straight-edge all is right, if not, a mark should be made where it does; then if two parallel lines be ruled, one from the first mark and the other from the second, the distance between them will show the amount of error.

Being assured that the focussing-screen and the dark-slide of the camera are in true register, we can proceed to test the lenses which we will assume is one of the earlier portrait combinations, though what is here said applies to all other kinds of lenses. In the absence of a focimeter, such as that just described, we must extemporise one. This we may do by placing eight or nine printed cards in a row, about four or five inches behind one another, supported, say, on corks, with a pin in each to hold the card. We focus sharply on the centre card and take a negative. If the card focussed upon proves to be the sharpest of the lot it is evident that the visual and chemical foci are coincident. If one of the others is the sharpest, then the sliding-tube should be marked, the card that was sharpest in the negative should be focussed, and the tube again marked. The distance between the two marks shows the distance the lens must be racked out after focussing in order to get sharpness in the pictures.

Another way is to pin a newspaper on a board placed in a slanting position in front of the camera, and mark the centre line of the printing, focussing on that and taking a negative. If this centre line is sharply defined, well and good. If not, that which is to be focussed upon and the tube marked as in the previous case. In making the tests with a portrait lens the camera should be placed at about the distance from the object as when taking a portrait, for it may be explained that as the conjugate focus is lengthened so is the difference between the two foci extended. Thus, in copying the same size difference is approximately double what it is with distant objects, and this makes a lens with a chemical focus inconvenient for copying purposes. In testing a lens for chemical focus the aperture should always be employed. Instead of having to

the lens after focussing the ground-glass of the screen may set back the required distance, but that becomes inconvenient when other lenses have to be used on the camera.

In testing lenses for outdoor work, such as R.R.s, it is best to use cards with bold print upon them out-of-doors at some little distance, and six or eight feet apart; a negative is taken as before. As these lenses, as a rule, have not sliding mounts, the

register marks must be made on the back or front of the camera. In a case of the periscopic doublet of two uncemented lenses they are adjusted by the makers of the camera so that the picture is taken at the chemical focus and not the visual one. If one of these lenses be put upon another camera a sharp picture will not be obtained unless the necessary correction after focussing is made for the chemical focus.

"OLD-HAND."

## FACTORIAL DEVELOPMENT FOR TANKS AND MACHINES.

HERE negatives have to be developed in total darkness in a tank or machine, it is, of course, impossible to employ the "Watkins" factorial method of timing the development, as this is, on the time of first appearance of the image. At the same time, it is important to adopt some method which will compensate, not only for any accidental errors in commanding the developer (such as naturally may occur in the hands of amateurs with limited time at their disposal), but also for variations of temperature, or for effects of deterioration in the developer or any of its constituents, if these have been kept any length of time before use. It may be sound advice to always keep the same temperature when developing, to use fresh developer for each plate, and to throw away any chemicals that have been in the house for some time. But these precautions are not always practicable.

The method which I am now using is so simple that I am greatly surprised to find that it is not universally known. All that is necessary is to test the developer by inserting a very small strip of exposed bromide or gaslight paper and watching it blacken up in ordinary daylight, like the paper does in an anemometer. To make the process more exact, I first insert the end of the slip and let it blacken. I then immerse a further length and count, with a watch, the number of seconds, or minutes, that elapse till this portion is indistinguishable in colour from the part first inserted. This time determines the speed of the developer, and it is only necessary to multiply this time by a suitable numerical factor, previously determined, in order to find the correct time of development of a properly exposed negative in the developer in question.

With metol hydroquinone I have obtained satisfactory results using the factor 20. At the same time the choice of a factor is not necessarily dependent on individual requirements to a considerable degree, and must be left for future experiment. The factor may, moreover, vary according to the paper used in making the preliminary test, although in a few experiments I have made bromide and gaslight paper have taken about the same time to blacken up.

This method compensates for variations in the strength of the developer, the activity of its constituents and the temperature. It possesses, moreover, the following advantages over the generally accepted "Watkins" method based on the time of appearance of the image:—

1. The time of commencement and the time of completion of

development are two very different things. In the ordinary method these are assumed to be proportional to one another, an assumption which is probably often far from true. In the present method the time of completion of development of the test slip is observed, and this is much more likely to give a correct indication of the time of completion of development of the negatives.

2. I suppose most photographers, like myself, have tried applying the ordinary factorial method to over-exposed negatives, which flash up in a few seconds, with the result that the negatives have been found afterwards to have been rushed into the fixing bath long before they had acquired proper contrast. According to the present method, an over-exposed negative will be developed for the same time as a correctly exposed one. It will, of course, get very black, but, if time is no object in printing, it will yield good prints, which it would not have done had its development been arrested sooner.

3. An under-exposed negative may suffer from under development, but such a negative would be highly liable to suffer more from fog while the appearance of the image was being observed in the ordinary method.

4. In employing the ordinary factorial method the strength of the developer must on no account be altered after once it has been applied to the negative. Only the time of development can be adjusted to compensate for excessive or defective speed. According to the present method, if the preliminary test shows the developer to have a higher or lower speed than is desired, the degree of dilution can be adjusted accordingly, and a second test made before making the actual development. In fact, it is quite easy to compound the developer to any desired speed.

5. A stale or exhausted developer is readily recognised, the test slip turning a dirty grey or reddish-brown colour, instead of a good black.

For ordinary purposes, the test slip should take not less than about 10 seconds or more than about a minute to blacken up. I believe that most photographers are liable to failures through miscalculating the speed of the developers they use. I have had a case where some freshly mixed pyro developer failed to produce any effect on the negative from some unaccountable reason. The present method affords a safeguard against any such failures, and I only regret that the idea had not suggested itself to me long ago.

G. H. BRYAN.

### MR. WATKINS ON PROFESSOR BRYAN'S METHOD.

Proof of the above article by Professor G. H. Bryan was sent

by us to Mr. Alfred Watkins, who writes as follows:—

The method which Professor Bryan describes is of very considerable interest, and has one point of novelty about it—the observation of the time for maximum visual development effect, instead of the minimum visual, or time of appearance. Making the observation in this way makes it unimportant how long the test slip is exposed (probably within limits) and the observation of development can also be made in daylight.

But the wording of the article almost makes the reader think

that this is the first suggestion of the use of a timing slip of exposed film to test the activity of the developer before the actual plate is developed. Readers of the "Watkins Manual" will find such a method described in the last three editions of the book, under the headings, "Development without dark-room light" or "Development by separate slip." The point in which my method differs is that I have advocated an observation of the time of appearance of the image on the slip, and that a slip of

a roll  
sca

the same plate be used. I introduced my plan by saying that it "practically amounts to making a preliminary trial of the activity of the developer before pouring it on the plate, and does away with all need of any dark-room light; a dark-room with a naked gas jet, which can be turned up and down, being all that is necessary."

The advantages, 2, 3, 4, and 5, which Professor Bryan states his test slip plan possesses over the "ordinarily accepted Watkins method" are all equally shared by the test slip plan I described in the Manual.

But I certainly think that the modification Professor Bryan has introduced in this test plan is an improvement on my original one, as it involves less preparation. In the few trials I have made I have found gaslight paper far better for the Bryan method than bromide paper, the latter seeming to take a different time for complete development according to the amount of light the paper was exposed to. With gaslight paper I found the method quite workable, and as far as I can see, quite sound, although it

would be desirable to define the limits within which the plate should be exposed to light.

Its one disadvantage is that the factor will vary with every brand of plate used, and that every user will have to find out the factor for himself. In this respect the development classification of plates on the Watkins speed card would be far more useful, as the factors for different plates would be in the same ratio as the figures given for the plates. Not being able to give a definite time in the instructions is, to my mind, a great drawback.

Frankly, I consider a thermo. time method more simple and useful than this test slip plan to those who wish to develop without dark-room light; for it gives definite times with only a thermometer to observe. The fault in most instructions for time development has been that the variation for temperature has been simply shirked, while the variation (a very large one) for different brands of plates has been treated as if it did not exist.

ALFRED WATKINS

## THE COLOUR-SENSITISING PROPERTIES OF THE ISOCYANINE DYES.

[In a lengthy communication to the current "Photographic Journal," Dr. S. E. Sheppard deals both with the chemical constitution and the optical sensitising properties of the dyes derived from cyanine. The following is the latter portion of the paper and contains the facts and conclusions more immediately concerned with the employment of the dyes in emulsions and as bathing solutions.—Eds., "B.J."]

THE apparatus used has already been described,\* but it is necessary to explain one or two of the terms employed. By "sensitising power" is meant the increase in sensitiveness conferred on a silver haloid by a dye for the region in which it acts. Strictly speaking, what is required is the sensitiveness or "speed" of the plate for each wave-length of light over which the sensitiveness extends, the values then being corrected for the energy distribution in the spectrum of the light source. For some purposes the division of the spectrum into two or three regions gives valuable results. In the case in question, namely, a comparison of the action of a body of dyes which affect much the same region of the spectrum, it is sufficient to cut off the blue and violet rays which affect the ordinary sensitiveness and measure the relative effect of the plates to light from 5,000 Å.O. onwards. For photographic purposes the value of the ratio *blue sensitiveness* =  $\chi$  is measured for a normal daylight yellow sensitiveness.

But for the photochemical comparison of this series of dyes it was unnecessary to reduce the measurements to daylight, and the ratio was measured with naked acetylene, screened in turn by 1 cm. of 4 per cent. potassium chromate and 1 cm. of 2 per cent. copper sulphate solution saturated with ammonia. The plates were exposed in the sensitometer, developed, bathed, washed, etc., in a special thermostat.

### Conditions of Sensitising.

The method for sensitising plates by bathing varies somewhat with the dyestuffs employed. The following methods were tested:—

- In plain water solution, varying the concentration, times of bathing and washing.
- In water solution, after a previous bath of alcohol or alkali.
- In semi-alcoholic solution, in ammoniacal solution.

It may be at once stated that the most consistent and effective results were obtained by the first method, which was therefore used for the comparisons. The trouble due to the bleaching of the dye solutions by dissolved carbon dioxide was obviated as much as possible by boiling the distilled water, rapidly cooling to 20 deg., and preparing the solution immediately before use. The following results were established by method (a):—

- (1) *Effect of time of washing.*—The result of a previous experiment with pinacyanol was confirmed, ten minutes being sufficient to remove excess of dye. This has, however, less effect than with the erythrosine dyes.

Time of washing.	Inertia.
0	10
60 secs.	5
5 mins.	2.40
10 "	1.70
50 "	1.73

Very prolonged washing, whilst not influencing the sensitiveness much, appears to improve the keeping properties of bathed plates. Experiments on this are in progress.

### Effect of Concentration.

Plates were bathed five minutes in solution of *p*-tolu-quinaldim *p*-methoxy-quinoline-ethyl-cyanine-iodide, prepared as described, and washed ten minutes.

Strength per 100,000 parts.	Inertia.
.5	4.20
1.0	1.70
2.0	1.73
4.0	2.80
8.0	3.20

A strength of 1 in 100,000 was therefore sufficient.

### Time of Bathing.

Plates were bathed in 1 in 100,000 of the solution.

Time.	Inertia.
1	3.25
2	2.20
5	1.72
10	1.78

Hence at this strength five minutes' bathing is sufficient. Generally speaking it appears that the three factors, concentration of bathing, and washing out exert a reciprocal action, there being, as in other cases of this nature, a maximum effect for any given set of conditions of action of desensitisers (Sheppard and Mees, "Proc. of Roy. Soc.," 1907). Thus, bathing in concentrated solution with prolonged washing gives the same effect as bathing in a weaker solution. The results, which agree with the theory that the dye forms an adsorption compound with the silver halide, may be expressed as follows:—

- (1) The most prolonged washing leaves a definite proportion of dye associated with the silver bromide.
- (2) The maximum effect is secured by removing excess of dye, but is not necessarily identical with the fixed minimum indicated in (1).

\* "Investigations on the Theory of the Photographic Process," p. 334.

Effect of Previous Baths.

The previous baths used were 20 per cent. sodium carbonate, and 2 per cent. ammonia. With dilute solutions of the dyes the alkaline bath had a favourable influence, but no greater increase of sensitiveness could be secured than with plain aqueous solutions under right conditions. But where, as in spectroscopy, films were to be bathed and used rapidly, the bath is of value, as using dilute solution of the dye no precautions against bleaching are required, and the carbonate bath causes but little extra fog. Ammonia had a somewhat similar effect, but also definitely increased the sensitiveness with some dyes. But it leads to fog, is uncertain in its action, and unnecessary with the iso-cyanins.

Comparison of Sensitising Power.

The plates were bathed five minutes in a solution 1 in 100,000 the dye and washed ten minutes, developed two minutes in a metol-hydroquinone developer, all the operations at 20 deg. The results are given in order of sensitiveness.

<i>p.</i> methoxy-quinaldine- <i>p</i> -tolu-quinoline-ethyl, etc.	1.97	93.4	1.07
<i>p.</i> tolu-quinaldine- <i>p</i> -chloro-quinoline-ethyl, etc.	1.95	89.0	1.12
<i>p.</i> tolu-quinaldine-methoxy-quinoline-ethyl-cyanin-bromide.	1.80	63.1	1.59
<i>p.</i> tolu-quinaldine-ethoxy-quinoline-ethyl-cyanin-bromide.	1.70	50.2	1.99

As the dyes are not simply related, and further experiments on simpler derivatives are required, it is not possible to draw any general conclusions as to the influence of substituted groups on the sensitising power. But by comparison of one with another it appears that ethyl and methyl groups have about the same influence. Comparison of (14) and (15) shows the great difference according as substitution occurs in the quinaldine or quinoline nucleus. The data are chiefly of interest for technical purposes and for comparison with the light-sensitiveness of the dyes themselves.

Relation to Light-Sensitiveness.

All the iso-cyanines, like the cyanines, are bleached by light. In pentine oil the reaction proceeds with measurable velocity. To obtain the relation, if any, to sensitising power, solutions were prepared in the spectrophotometer of equal original strength of absorption at their maxima, and the times measured which they took to bleach to one-third of the original absorption. The reciprocal of this was taken as a measure of the light-sensitiveness. This issue showed a definite parallelism between light-sensitiveness and sensitising power. E. Vogl ("Wied. Ann.," 1891, 43, 449) found that in the eosine series sensitising power and light-sensitiveness were more or less related. Abney's theory of the action of sensitising dyes was that light decomposed the dye-stuff, the product acting as a nucleus for reduction, and he hence considered the light-sensitiveness as of primary moment. It has been shown, however, that the addition of the decomposition-product has no effect in making plates developable, and when different groups

of dyes are considered the parallelism does not hold good (J. M. Eder, "Beiträge zur Photochemie, etc.," Tl. III., p. 1 *et seq.*), although it certainly appears valid within a group of dyes of the same constitution, so that both phenomena probably depend on the same photochemical change in the molecule. In the following table the results are resumed.

TABLE 10.

The numbers refer to the dyes tabulated in Table 9.

The Relation between the Sensitising Spectra and the Absorption Curves of the Dyes.

The absorption curves of the dyes in alcohol and water have already been mentioned. The sensitising spectra were obtained by exposing the plates, bathed in the dye-solution in the manner detailed, in a grating spectrograph to standard acetylene light. The plates were exposed two minutes and developed two minutes in the standard metol-hydroquinone developer. They were dried after bathing in a special cupboard by a current of air drawn over calcium chloride. The densities were measured for every 10  $\mu$  in a special carrier. Experiment showed that under proper conditions of sensitising the densities in the blue-violet region of the spectrum were not depressed by bathing in isocyanin solutions. For the comparison of sensitising and absorption spectra the curves are only given from 490  $\mu$ .

quite evident from this and from the curves that the sensitising depend directly upon the maxima in the absorption spectra of the dyes. The bands are shifted some 10 to 15  $\mu$ m toward the compared with the aqueous absorption spectrum, the  $\alpha$  band of the red being in general shifted slightly more than the  $\beta$ . Compared with the alcoholic spectrum, the  $\beta$  band is not shifted; the  $\alpha$  band shifted some 10  $\mu$ m. An attempt to measure spectrophotometrically the absorption of a silver bromide film stained with one of the dyes failed owing to the rapid bleaching of the dye. The data are in good agreement with the application of Kundt's method and show that in this series the sensitising maxima can be predicted from the absorption spectra, and that structural changes will affect the absorption and sensitising spectra in a similar manner. Of course, leaves the question as to the physical basis of Kundt's method.\*

### Theories of Sensitising.

A complete theory of sensitising should give an explanation of two phenomena (a) the taking up of the dye; (b) the photochemical action in virtue of which the halide becomes developable. As in the first, the problem is part of the general one of dyeing. It has been shown that the dye must stain the halide grain, and that which vigorously sensitise are all so-called substantive dyes. This position has been further strengthened by the investigations of Hübner [Eder's Jahrb. f. phot., 1894, p. 189, and 1903, p. 128] and K. Kieser ("Dissertation," Freiburg i. B., 1904, "Eder's Jahrb. f. phot.," 1905, p. 334); just as in ordinary dyeing it is difficult to explain all the facts with either a purely chemical or a purely physical theory of the process. Linder and Picton ("Journal of Chem. Soc.

Trans.," 1905, 88, 1,933) found that in simple substantive dyeing there were two stages. In the first or "coagulation" stage chemical processes occur (*loc. cit.*, p. 1,914) which exhaust themselves before the second or "colour absorption" stage commences. In the latter the dye is absorbed as a whole, and the evidence points to a physical attraction between the dye and the coagulant, which may be due to the electric attraction of oppositely charged colloids. A considerable amount of work in recent years has gone to show that a large number of dyes exist in solution in the colloidal state. The writer is at present engaged on a continuation of the present research concerning the solution state of dyes and its relation to their absorptive and other properties. It should be pointed out that the experiments on the conditions of sensitising detailed here are in agreement with the view that the dyeing phase of "sensitising" is a process of adsorption. As regards the optical or photo-chemical action of sensitisers, our knowledge is very uncertain. A former theory connecting sensitising with fluorescence was discredited by Eder's researches. A modified form of this has been recently suggested by J. Stark ("Phys. Zeitschr.," 1907, 8, 249), based on the idea of "latent" fluorescence. It has been shown that fluorescence in general is a characteristic property of molecules of definite composition containing a fluorophor group (R. Meyer, "Zeit. physik. Chem.," 1897, 24, 468). Stark ("Physik. Zeitschr.," 1907, 8, 81) showed that benzene and simple benzene derivatives possessed ultra-violet fluorescence, and that the benzene nucleus is in itself a fluorophor, some form of fluorescence being always associated with bodies giving a banded spectrum of absorption. It is maintained by Nichols and Merritt (Nichols, "Jahrb. f. Elektronik," 1905, 2, 149) that the fluorescent spectrum arises from absorption in the band spectrum, its distribution depending on the superposition of absorption and emission. Every wave-length in the fluorescent spectrum is excited by radiation, whether of longer or shorter period. Stark terms "latent" fluorescence such which is so weak that it is hidden by reabsorption. Suppose now on the single molecule or smallest aggregates of a substance absorbing and reacting to blue and violet rays—AgBr, for instance—a few molecules of a substance possessing blue or violet fluorescence are fixed. Radiations of such period that they are only slightly absorbed by the AgBr, but are strongly absorbed by the dye, give rise to the whole fluorescent and so to the blue and violet fluorescence which chemically affects the silver bromide. This theory cannot be considered as completely proved yet, although Stark claims to have proved the existence of a blue or violet fluorescence in the case of the sensitisers erythrosine and cyanine. Admitting the comparative feebleness of this, it becomes necessary, owing to the effects of superposed absorption, to work with very thin layers. Stark considered that he had obtained an effect on the photographic plate, using a quartz spectrograph. It has appeared possible to the author that examination in an ultramicroscope by Zsigmondy and Siedentopf's second method, with a fluorescent ocular, might yield some results, and experiments on this are in progress.

The work detailed in the foregoing was carried out during the winter and summer semesters of 1906-1907 at the Physical Institute of the University of Marburg, and the writer desires to express his thanks to the authorities for the facilities afforded him, and in particular to the Director, Prof. Richarz, and to Prof. Karl Schaum for their continuous interest and advice. S. E. SHEPPARD.

TELEGRAPHIC PHOTOGRAPHY.—Inventors of the telegraphic transmission of photographs, such as Korn and Belin, are to see the fruit of their labours, not only in the physical or industrial field, as witness the following from our contemporary, "Great Thoughts." "This scientific wonder suggests easily the very reasonable probability of not only transmitting, but preserving, the likeness of human identity, or, rather, spiritual entity, despite space, time, or other human limitation. Spiritual entity is pervasive, and, as widely as it may transmit itself, or be transmitted, it does not lose its recognisable, inherent traits of conscious character as emphasised by the life possessed, expressive in both thought and action. In other words, the soul expressions of our complex nature are recognisable anywhere. Whether a man speak our language or is of our nation or not, that he is or is not a Christian can always be as clearly perceived as are the lineaments of a countenance with which we are familiar, whether we see it in London, New York, Paris, or in our own home."

\* This work was finished. A. Byk ("Zeitschr. physik. Chem.," 62, 1908, 487) in a paper on the photo-chemical re-action, comes to the conclusion that the ion and not the absorption is the determining factor, this applying also for the sensitising action of dyes. According to this theory, with changing wave-length the action increases with increasing coefficient of refraction, not with the amount of absorption. Many of the dyes used show anomalous dispersion (Vogel, 1874, 7, 978), which is in agreement with his position.

## Photo-Mechanical Notes.

### Half-Tone Screens.

A screen specially intended for the preparation of half-tones to be printed on news paper or other coarse paper has been patented by Carlo Jacobi, 470, Campo St. Andrea, Venice. The screen contains intersecting sets of parallel opaque lines having greater or less thickness. According to the specification, No. 5,109, 1908, fig. 1 represents a screen in which is inserted among the black wide lines *a*, in the transparent space, only one thin line *b*. In fig. 2 in the

Fig. 1.

screen, between the black wide lines *a*, are inserted two light thin lines *b*<sup>1</sup> *b*<sup>2</sup>.

In both cases the thin lines and their crossings prevent to only a small extent the passage of the light through the luminous parts, leaving reproduced on the negative, in the form of dots, only the crossing of the wide lines *a*, whilst in the obscure parts of the original, where the light is less intense, the crossing of the thin lines *b* and *b*<sup>1</sup>, *b*<sup>2</sup> with the wide lines *a* appears, and the light not being intense enough to surmount the crossing of the wide lines with the thin ones makes the wide lines appear of double width.

Supposing then that in the screen there are, for instance, twenty

Fig. 2.

wide lines *a* for each centimetre, with twenty thin lines *b* inserted, an effect of reproduction will be obtained as if we had used a screen, having in the obscure parts lines of double the width of those in the luminous parts, and so the greatest possible desired effect in light and shade will be obtained.

Using the screen with only one thin line (fig. 1) inserted, regulating carefully the distance of the screen from the sensitive plate, there will be obtained at the same time the variation in the points of intersection and, consequently, a greater variety of mezzo-tints.

### PHOTO-MECHANICAL PATENTS.

The following patent has been applied for:—

**ETCHED PLATES.**—No. 17,480. Improvements in process work for producing etched plates and other like objects for printing and other like process work. Robert Bain and Robert Davos Bain, 5, Henrietta Street, Covent Garden, London, W.C.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications have been received between August and August 22:—

**DISPLAY OF PHOTOGRAPHS.**—No. 17,285. Improvement arranged for the representation of photographs. Eduard Otto Zechm 56, Middleton Square, London, E.C.

**COLOUR SCREEN PLATES.**—No. 17,309. Improvements in colour screen plates and their uses. Henry William Hamblin Palmer, 43, Martin's Lane, London, W.C.

**CAMERAS.**—No. 17,624. Improvements in photographic cameras. Optische Anstalt C.P. Goerz Akt. Ges., 31, Bedford Street, Strand, London, W.C.

### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**REFLEX CAMERAS.**—No. 15,199. 1907. The invention relates to a type of camera in which the focussing of the image up to the moment of exposure is done by means of a mirror in the lower of the camera. This mirror reflects the image cast by the lens on an opaque focussing screen placed directly opposite the lens. The image, reflected in the mirror, is examined through a lens placed in the top or other part of the camera. The principle of the apparatus will be understood by instancing one of the twelve figures referred to by the patentee.

In the figure the camera is of the ordinary box type, constructed to receive a roll-film B and with a focal-plane shutter C. The surface of the blind of the shutter C serves for the opaque focussing screen D, it being made with a white surface to receive the picture. In the top a large observation opening *e* is formed, fitted with a viewing screen E, and in the interior a concave mirror F is placed in such a position that the picture on the focussing screen is reflected therein and re-focussed into the plane of the opening into a plane between it and the eye of the operator, so that the image may be viewed upon, or apparently upon, the viewing screen E without approaching the eye to the opening. The mirror

is pivoted to swing across the field of the lens G and close the observation opening *e*, in which is set the viewing screen E. As much as the opaque focussing screen D is an appreciable distance in front of the focal-plane in which the sensitive surface is placed, it is necessary to adjust the lens G to bring the picture which has been focussed upon the opaque focussing screen D into focus upon the sensitive surface at B. To accomplish this upward movement of the mirror F to close the aperture of the viewing screen E rotates a wheel or segment *g*<sup>2</sup> to rack back the lens G the desired distance. The mirror F is pivoted upon a point on the side of the lens tube *g*. In front of the lens a diaphragm

H with two apertures or "stops"  $h$  is mounted to be moved as the lens simultaneously with its to and fro movement by a wheel segment  $g^1$  to present a large aperture during focusing and a smaller aperture during the exposure of the sensitive surface at B. The mirror F is held in position by a catch  $f^1$ , and moved upwards by a spring. It is necessary that the several movable parts of the camera should operate in succession after one another, and that the lens should be adjusted and light excluded before the observation opening  $e$  before the blind C moves to expose the sensitive surface B. To effect this the mirror F is held in position against the tension of a spring by a catch  $f^1$ , and the mirror C is held by a detent or catch  $c$  in the usual way. When the catch  $f^1$  releases the mirror F the spring causes the latter to move into the position to close the aperture of the auxiliary focusing screen E, this movement being effected simultaneously with the wheel segments racking back the lens G and the diaphragm H, and when the aperture is closed the mirror strikes the blind catch and releases the blind C for the purpose of exposing the sensitive surface B. John Edward Atkinson, Altrincham, Cheshire.

**BOOK-MARKERS.**—No. 24. 1907. The invention relates to book-markers, and has for its object a book-marker adapted to be used as a photographic mount or for other purposes. In carrying out the invention a mount of any suitable shape is provided with a slot, into which a photograph or slip may be inserted from the edge. A suitable method of making such a combined book-marker and photographic mount is to shape a piece of cardboard, or other substance, and then, by means of an adhesive or mucilage, fasten a plain or fancy cover thereon, this cover having an opening behind which the photograph will be located and secured to the base or ground portion at one side opposite the opening to allow of the photograph being slipped in. Slits may then be provided to form a tongue for clipping a page in the way, or the tongue may be formed before the cover is secured to the base. Howard Maryat, 28, Hatton Garden, London.

Following complete specification is open to inspection before the Patent Office.

**SCREEN-PLATES.**—No. 17,065. Method of producing polymeric screens for the production of photographs in natural colours. Szczepanik.

## New Trade Dames.

—No. 304,685. Photographic cameras and apparatus in Class 8. Houghtons, Ltd., 88-89, High Holborn, London.

—No. 304,958. Prepared paper for photographic purposes. Limited, Britannia Works, Roden Street, Ilford, London, E.

**NON-STRESS GASLIGHT PAPER.**—The Birmingham Photographic Co. state that they have now extended the Nonstress quality of their paper to include gaslight also, which will be sold as "Nonstress."

**DAVIS AND SONS**, of Lancaster, had the honour conferred on them last week of being summoned to Abbeystead House to take the last of the Prince of Wales and members of the Earl of Devon party. Copies of the photographs were sent to the Prince and since then Messrs. Davis have received a letter from Sir John Lubbock, the Prince's equerry, which says: "The Prince of Wales has been very kind to say that he thinks the groups are very good."

**GRAPH-PHOTOGRAPH.**—According to the "Daily Express," a Swedish engineer, named Sven Berglund, has constructed an apparatus, the graphophone, through which the problem of reproducing human voice perfectly clearly without the grating sound of a gramophone is said to be solved. The chief feature of the new apparatus is that light and photographic plates instead of the usual gramophone records and pins. The apparatus is particularly adaptable for a combination of speech and photography, as the pictures, as well as music or speech, can be photographed simultaneously.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Stripping Negatives Without Hydrofluoric Acid.

A stripping method that has advantages over those in general use is the following (writes Mr. Edgar Simpson, in the "Photographic Monthly" for September):—The negative to be stripped is immersed for from ten to fifteen minutes in A, water, 100 ccs.; bisulphite of soda at 40 deg. Beaume, 25 ccs. It is then rinsed under the tap or left for fifteen to twenty minutes in the following solution:—B, water, 100 ccs.; formalin (40 per cent.), 15 to 20 ccs.; carbonate of soda, 5 grammes. (This should be filtered before use.) Rinse for a few minutes and rub the face of the negative lightly with wet sponge or cotton wool. Leave in the rack to dry.

When perfectly dry, cut round the negative about an eighth inch from the border. Lift up one corner with a penknife, and the film can be easily peeled off and is ready to be printed from.

One side of the film is bright and the other dull. There is no possibility of the image being distorted in any way. It remains in its original size exactly, and remains flat. I may note that all my experiments were made on negatives which had been fixed in the following:—Water, 1,000 ccs.; hypo, 250 grammes; sulphite of soda, 20 grammes. After complete dissolution add: Sulphuric acid, 5 ccs., stirring all the time. This should not be used until the solution has cleared.

### Carbon Tissue as a Backing for Plates.

Mr. F. C. Davis, writing in "The Amateur Photographer and Photographic News" for September 1, on backing plates, says:—"Lately I have been using one which hits the mark for economy, efficiency, ease of application and removal, and although by no means unknown it seems rarely used. It consists of black carbon tissue and it is immaterial whether it is sensitive or insensitive. My method is to cut the tissue about one-eighth of an inch smaller than the plate to be backed, soak it for five minutes in cold water, and then place between sheets of fluffless blotting paper under a press (anything heavy will do) for a few minutes. By this time it should be as dry as is necessary, for it must still be quite limp. Take the tissue to the dark room, then with a finger-tip and very little glycerine rub all over the glass side of the plate to be backed, which should be held by the edges to avoid being contaminated; place the tissue in position (back side to the glass), and gently rub down with a clean handkerchief; it sticks instantly, and you have a most efficient backing, giving great freedom in use on strongly lighted subjects. Personally I have obtained better results with this than with any other form of backing. To remove the tissue before developing you have only to raise one corner and it strips off easily, and can be used over and over again, following the same method. If it is not to be used at once it should be thoroughly dried and stored till wanted. Perhaps its great charm, next to efficiency, is its cleanliness."

### Waistcoat-Pocket Cameras.

It is not reasonable to suppose (says a writer in "Photography and Focus" for September 1) that these little cameras will ever supplant the big ones, which enable an image of a fair size to be seen and arranged on the focussing screen; but if they will not supplant them, at least they supplement them. By pocket camera, we do not mean, in this connection, any camera that can be got into a pocket, but the camera which is so truly portable that it can be carried *always*, with an adequate supply of plates, taking up no more room in the pocket than, say, a cigar case. Only a few of the so-called pocket cameras can be regarded as strictly within these limits, and we do not wish to decry the many excellent patterns which lie outside them. They, too, have their uses. But for the waistcoat-pocket cameras there is a fine field of utility, and one which they alone can occupy.

For the last two years the writer has carried, almost without exception, such a camera and half-a-dozen small plates. It occupies no serious share of his pocket room, and no one would suspect that he had an efficient means of making a 15 by 12 photograph concealed about his person. Yet lying before him, as he writes, are several enlargements of that size, which, in point of detail, leave nothing to be desired yet which had their origin in the tiny

apparatus just mentioned. They record pictures which certainly would not have been obtained but for the pocket camera, for they were all taken at times when the use of anything larger was not possible.

## New Books.

"Zelluloid und seine Verarbeitung." By Louis Edgar Andés. Leipzig: A. Hartleben. M. 6.80.

This treatise on a substance of great importance in photography comes from the pen of a writer whose name is known as an expert in this branch of technology. It is devoted for the most part to the many uses of celluloid in the manufacture of articles of fancy ware, decoration, etc., but the earlier parts of the volume contain useful chapters on the properties of celluloid and the behaviour of the pure substance towards various solvents and other reagents. Obviously in a book on a trade which relies largely on the preservation of its methods secret, one cannot expect to find anything like a full description of manufacturing processes, and therefore in the section on photographic celluloid films it is not surprising to see that only one type of machine is described, evidently from a patent specification. A chapter deals with the use of celluloid as the basis of mirrors and a silvering formula of the ammonio-silver type is recommended. The book contains formulae for the making of celluloid varnishes, and in general, although its subject matter is not throughout of a highly informative character, it is perhaps the best technical treatise on celluloid which can be obtained.

"Dreifarbige Photographie nach der Natur." Second edition. By Dr. A. Miethe. Halle a/S: W. Knapp. M. 2.50.

This is a revised edition of the text-book, issued 1904, in which Dr. Miethe described the methods employed by him for three-colour photography by the additive process, using the then newly introduced ethyl-red. A good many new sensitisers of the isocyanine series have been introduced since then, but Dr. Miethe still declares in favour of the first of the series. In other points, too, the advice given for the production of projections in colour by the additive method differs only in reference to minor details. The volume contains as a frontispiece a reproduction in colours from a set of negatives obtained in one-tenth of a second on ethyl-red bathed plates. The subject is a suburban scene, photographed by Dr. Miethe from a balloon at the height of 450 metres.

WOOD CARVINGS.—Those of our readers who make a hobby of wood-carving should be glad to learn of a new series of designs now commencing publication monthly at one shilling per issue. The designs are by Mr. W. T. Whitehead, artist-draughtsman, of 10-11, Fetter Lane, London, E.C., and the large lithographed sheet contains eight excellently varied shaded drawings for the use of the wood-carver. In beauty of classical design and fitness for their special purpose we know of nothing better. The portfolio is published by the designer at the above address.

## New Apparatus, &c.

The "Biermann" Exposure Indicator. Sold by the Arthur Cox Illustrating Co., Ltd., 63 and 64, Ludgate Hill, Birmingham.

This device is a card calculator, about the size of a quarter-plate, the use of which is supplementary to that of the Watkins or Wynne meter; that is to say, Mr. Biermann bases his measurements on the darkening of the Watkins or Wynne actinometer paper, but in calculating the exposure from the latter he makes allowances for factors which do not usually enter into the calculations made on the lines of the ordinary meters. The chief addition in this respect is the scale relating to variations in the exposure due to the type of lens and of shutter. Mr. Biermann certainly adds to exactness in working when he enables one to allow for the difference in light given by focal plane shutters and those of the less efficient type used on or in the lens. This factor he combines with that for the lens, and therefore we cannot separately ascertain the allowance which is made for each separately. And this we would rather like to do, inasmuch as we see it stated in some notes which accompany the meter that "the modern large anastigmats are faster than the

older types of rapid rectilinear lenses." This, of course, we imply the use of both at the same focal aperture, but we are to know what figures the alleged increased speed of the modern is based upon. Messrs. Hurter and Driffield, it will be remembered in the "Actinograph," provided a similar adjustment for double, and triplet lenses, which latter they placed slower three (for the same aperture) on account of the greater number of reflecting surfaces. As many of the recent anastigmats are of the triplet type, and as others are composed of very thick glass data on which their relatively greater rapidity is based should be of interest.

The design of the calculator allows of a great range of exposure being given—from 60 to 1-1500 seconds or minutes, according to the reading of the actinometer. The scale of subjects is also a wide one, ranging from clouds to dark interiors, and here again the position of the shutter lens scale mentioned above is usefully employed to make allowance for the longer exposure necessitated in weak light. An inset table is also provided to allow for the extra exposure required by the greater focal extension of the lens when photographing distant objects. A supplementary table is also given, applying the readings of the exposures in weak lights to the exposure of Autochrome plates, which should be evident that the "Indicator" has been very carefully thought out, and is certainly a good deal more than a variety of other exposure devices. While it may not be the final method of dealing with admittedly difficult variations, it is, nevertheless, a very valuable addition to the outfit of the painstaking photographer. Its price is 1s. 6d.

## New Materials, &c.

Rectangular Lantern Slide Masks and Square Gauge. Made by Roffey and Clark, 12, High Street, Croydon.

Everybody who has had much lantern slide masking to do knows that there is nothing more certain than that it is almost impossible to find a series of masks which will correspond to every lantern picture made by reduction, or, for the matter of it, to the best select that produced by contact. For this reason the method of building up the mask by the use of opaque strips of paper with a clean edge is by far the most convenient and efficient method of slide masking, and one which we ourselves have used regularly at least fifteen years, at first cutting the masking strips out of the ordinary black needle-paper of the stationer. It has now been left to Messrs. Roffey and Clark to issue a new form of masking strips, which, so far as we can see, admit of no further improvement. It consists of a paper white on one side and black on the other, this latter surface being thin and with an adhesive. The black surface, therefore, has only to be moistened and laid in position on the slide when it firmly adheres to a varnished or unvarnished surface; the white upper surface of the paper may then be used for memoranda or the blank surface usually employed. Messrs. Roffey and Clark also supply the strips as a card, ruled into squares, on which the lantern slide is laid when masking, the lines serving as an effective means of indicating the proper right-angled form of mask. The strips are conveniently packed each in a separate envelope, with the width marked thereon, and the whole outfit may be recommended as a lantern slide makers as the best available means of proceeding with the least labour what is usually an uncongenial task. The price of the outfit, containing strips sufficient for one dozen slides, is 10d., post free 1s.

"Wratten" X-Ray Plates. Made by Wratten and Wainwright, Croydon, Surrey.

In this plate Messrs. Wratten and Wainwright have embodied the results of improvements in emulsions for X-ray work, made as a result of experiments in their laboratory, and with the object of securing rapidity and density without the necessity of a very thick film of precipitate. The plate depends on the use of a heavy metallic salt which a precipitate can be formed in the emulsion along with silver, which precipitate has the property, not only of stopping the X-ray and transferring it by secondary radiation to the neighbouring silver particles, but of greatly lessening the amount of the X-ray radiation in the plate, so that the resultant plates are not only fast and capable of giving great density and contrast, but also of appreciably sharper definition in fine detail than can be

an emulsion made of silver bromide only. The precipitate is largely removed in the fixing bath, and has the effect of giving the finished negative a whitish opalescent appearance when looked at, and a yellowish appearance when looked through. It does no harm either for visual or printing purposes, nor is it affected by light, so that it does not lessen the permanence of the negative; it can be completely removed if desired by a bath of weak acid during washing. As regards convenience in use, the new plate also represents an advance, for each is packed in a separate wrapping, on the outside of which the glass side of the plate is indicated. This has been very discovering a make of soft white paper which, it is found, can be laid in contact with the film of the plate without injury, and the result to the X-ray photographer is that he can take each plate from its box and use it without going into the dark-room until it is necessary to develop. The plates are issued in the following sizes and at the following prices:—Half-plates, 6½in. by 4½in. 4s. 8d. per dozen; whole-plates, 8½in. by 6½in., 8s. 6d. per dozen; 10in. by 8in., 10s. 6d. per dozen; 12in. by 10in., 20s. per dozen; 15in. by 12in., 25s. per dozen.

### CATALOGUES AND TRADE NOTICES.

**DALLMEYER CAMERAS.**—A neat list of the cameras of substantial build, such as are necessary to do justice to the modern anastigmatic field and large aperture, has been issued by Messrs. Dallmeyer, Ltd. The "Correspondent's" camera is particularly worthy of notice. The list is obtainable free from 25, Newman Street, Oxford Street, W.

**"SERVICE" SALE.**—A list running to thirty-six pages has been issued by the Service Company, 292-293, High Holborn, London, W.C., in reference to the clearance sale of photographic apparatus and other optical goods. The list includes a great variety of apparatus.

**SEPTEMBER "CITY SALE" BARGAIN LIST.**—The City Sale and Exchange send us from their depot at 54, Lime Street, London, E.C., a large 10-page list of second-hand apparatus in the way of lenses, and field cameras, and enlargers, which they will be pleased to send on application.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### SATURDAY, SEPTEMBER 5.

North Middlesex Photographic Society. Outing to Pitsea and Benfleet.  
 Wandsworth Photographic Society. Excursion to the Wrens Nest, Dudley.  
 North Suburban Photographic Society. Excursion to Bookham. P. C. Cornford.  
 Rugby Photographic Society. Excursion to Stanford. C. C. G. Cooke.  
 Chelsea and District Photographic Society. Excursion to Stanmore.  
 Manchester Amateur Photographic Society. Ramble to the Goyt Valley.  
 Leeds Camera Club. Visit of Hull Photographic Society.

#### MONDAY, SEPTEMBER 7.

South London Photographic Society. Conversazione and Opening of Winter Session. Monthly Competition. Lantern Slides.  
 Southampton Camera Club. "Hints on Preparation of Exhibition Work, with Examples." A. E. Henley.

#### TUESDAY, SEPTEMBER 8.

Royal Photographic Society. Ordinary Meeting for the Election of Members. Autochrome Slides will be Shown.  
 Manchester Amateur Photographic Society. "The Subtle Differences Between Good Slides and Fine Slides." James Shaw.

#### WEDNESDAY, SEPTEMBER 9.

North Middlesex Photographic Society. "How to Work the Optical Lantern." H. Stuart.  
 Southampton Camera Club. Ramble to Romsey and its Abbey. S. G. Kimber.

#### THURSDAY, SEPTEMBER 10.

Wandsworth Photographic Society. "Carbon Printing." Demonstrated. R. J. Fumell.

MR. ORMISTON SMITH, whose cinematographic work has delighted many Alhambra audiences, on ascending the Jungfrau last week in company with three guides, found four Germans, including two young women, exhausted and half-frozen near the summit. Restoratives having been applied, the Germans explained that they had lost their way in the fog, being without guides, and had spent two days in holes dug in the ice for warmth. The guides brought down the Germans to the Concordia hut, whence, after a long rest, they descended to the hospital at Grindelwald. Without the aid of the Englishman's party all would have been frozen to death in a few more hours.

## Commercial & Legal Intelligence.

**SERIKON, LTD.** (Photographic Goods Manufacturers, Whetstone).—A 5 per cent. mortgage dated August 5, 1908, to secure £400 charged on land and erections, at Wickford, has been registered. Holder—R. A. McQuitty, 34, Fenchurch Street, E.C.

### NEW COMPANIES.

**WILLIAMSON, DRESSLER AND Co., LTD.**—Capital, 1,000 in £1 shares. To acquire the business of a dealer in cinematograph or other films carried on at 27, Cecil Court, Charing Cross Road, W.C., as "Williamson and Company," to adopt an agreement with J. Williamson, and to carry on the business of manufacturers of and dealers in cinematograph, photographic and other films, optical and magic lanterns, lantern slides and photographic and optical goods of all kinds, etc. The first subscribers are: J. Williamson, 11, Wilbury Villas, Hove, film manufacturer; G. F. Bauerdorf, 17, Leinster Gardens, S.W.; A. J. Williamson, 11, Wilbury Villas, Hove; A. H. Wibling, 6, Woodside Avenue, Brighton; E. F. Stimson, Aldersmead, Tooting Bec Common, S.W.; F. G. Thomas, 63, Elgin Road, Croydon; and W. N. Kearsley, 173, Hanbury Street, Mile End, E. No initial public issue. The first directors are:—J. Williamson and G. F. Bauerdorf (both permanent). Qualification, £100. Registered office:—27, Cecil Court, Charing Cross Road, W.C.

## News and Notes.

**"SOUTHSEA AND PORTSMOUTH AT A GLANCE."**—Under this title the municipality of Portsmouth have issued a substantial volume, very fully illustrated with photographs, and detailing the attractions of the neighbourhood for temporary and permanent residence. The book is obtainable free from the Portsmouth Corporation.

**DAMAGE BY FIRE.**—During a fire which broke out last week in an office block at 22 to 24, Lombard Street, Belfast, the premises occupied by Mr. A. Black sustained considerable damage.

**AN ANTIPODEAN ECHO OF AMALGAMATION.**—*"Sharland's New Zealand Photographer,"* in announcing the amalgamation of our weekly contemporaries, earns our gratitude for its note of sympathy with us in our celibate loneliness. It writes:—

*The Wail of the "B.J."*—All the other weeklies having mated  
 "One for thou and one for thee,  
 Never, oh never! a one for me."

**CANVASSING AMENITIES.**—Last week a sequel to a row which flavoured of trade jealousies was heard in Portobello Police Court, when Mark Chisholm, a photographer's canvasser, of 3, Baxter's Place, Edinburgh, appeared on a charge of assaulting a rival canvasser named John Foley, who carried on business next door to accused in Bath Street, Portobello. He pleaded not guilty, and evidence was led. It was stated that Chisholm went to Foley's studio and interfered with him. He tore some photographs out of his hand and struck him two blows in the face, to the effusion of blood. Accused denied these allegations, and stated that two young ladies came into his studio and informed him that the man next door had said that if they got their photographs taken at Chisholm's they would not get them for two or three months, perhaps not then. He thereupon went into Foley and asked him why he was interfering with his business. Foley told him to mind his own business, and struck him a blow on the body. Chisholm was convicted about eleven months ago for assaulting a rival across the street. The charge was found proven, and he was fined £2, with the alternative of twenty days' imprisonment.

**SUICIDE OF A CARAVAN PHOTOGRAPHER.**—An inquest was held at Newhall, near Burton-on-Trent, relative to the death of William Spilsbury, a travelling photographer, whose body was found in his caravan. It was stated that the body, fully dressed, was lying on the bed in the caravan at the time the discovery was made, and beside it stood a cup containing a small quantity of cyanide of potassium. The deceased's housekeeper, Florence Lauriston, said that some time previously the deceased mixed a cup of poison and suggested that they should die together. "Suicide by poison during temporary insanity" was the jury's verdict. Spilsbury, it is stated, was a native

the Potteries, and had a flourishing business in Hanley some years ago. Latterly he had travelled, making Swadlincote and Newhall his headquarters.

**AN EARLY EXAMPLE OF TYPOGRAPHY.**—According to a "Times" correspondent, several interesting archaeological discoveries were communicated to the Academy of Inscriptions at its last meeting. The most important was a clay disc, 16 centimetres (nearly 6½ in. in diameter), having on its two faces over 120 pictorial signs representing men, animals, trees, and the like. This discovery was made by the Italian investigators at present working at Phætos, in Crete. According to M. Salomon Reinach, the remarkable thing about the disc is that the signs are not engraved but imprinted by means of punches, and may therefore be regarded as a first attempt at typography, about 4,000 years ago.

**THE KORN SYSTEM OF PHOTO-TELEGRAPHY IN DENMARK.**—Our Danish contemporary, "Ingeniøren," contains a report of a lecture by Professor Korn, of Munich, in connection with the first apparatus being installed in Denmark for the daily paper, "Politiken." The apparatus described was similar to the installation recently experimented with at the offices of the "Daily Mirror" in London, and it is unnecessary to repeat the details of the arrangement for employing the variations in the resistance of selenium under the influence of light to attain the desired result. After the lecture Professor Korn showed the apparatus that is to be used by the daily paper, "Politiken," in Copenhagen, and "Dagens Nyheter," in Stockholm. A photograph was telegraphed from the one apparatus to the other, and after that an attempt was made to receive a photograph sent from Berlin. This was, however, not successful, because of some fault on the circuit by means of which the current from Berlin was considerably weakened. Professor Korn, however, claims to have sent photographs successfully over much greater distances, but it appears that mishaps like this will always be liable to take place as long as the circuits used are not especially arranged for the process.

**PHOTOGRAPHIC TRADE IN BAHIA.**—According to a report on the trade of Bahia (Brazil), which has just been issued by the Foreign Office, photographic appliances command a considerable sale at that city. At the present time the various appliances in question sold—cameras, lenses, plates, printing papers, etc., are supplied by the United States, by Germany, and by France.

## Correspondence.

- \**\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*
- \**\* We do not undertake responsibility for the opinions expressed by our correspondents.*

### THE R.P.S. FELLOWSHIP FOR HON. SECRETARIES.

To the Editors.

Gentlemen,—I notice in your correspondence columns this week a letter from a correspondent who is evidently much in favour of the Fellowship of the R.P.S. being granted to hon. secretaries who, by reason of long years of service spent in the interests of their respective societies, seem to deserve some recognition of their efforts.

Whilst agreeing that services of this sort deserve recognition in some shape or form, I would ask, why on earth grant them the Fellowship of the R.P.S., when one essential condition of the bestowal of this title is that the recipient thereof shall have made some practical contribution towards the dissemination of photography? Surely it is hardly logical to contend that because a man has worked hard in order that his society might contribute towards the advancement of photography, he, personally, is deserving of the honour which is, after all, meant only for those who have done practical work in this direction. If he has contributed practically, all well and good, but I certainly fail to see otherwise why he should be honoured in this particular way. It surely would be most unfair, both to those who have already received the title and to those who may be working now in the hope of receiving it at some future time. It is, of course, well known that the office of hon. secretary to a flourishing society is no sinecure, and I quite agree with Mr. Lloyd

in thinking that this should be recognised, but I cannot help think that the conscientious hon. secretary, who had this particular honour thrust upon him on the score of his having been an ex-officer, and not necessarily a good photographer, would feel much like the recipient of a "consolation prize." Do by all means let us keep our "honours" as honours, and not cheapen the thrusting them on people who, while deserving of all credit for efforts, have no real claim to such a title as F.R.P.S.—Faithfully yours,

MURIEL DAIN.

8, Ribblesdale Road, Hornsey, London, N.  
August 23, 1908.

### THE REVERSING ACTION OF RED LIGHT.

To the Editors.

Gentlemen,—The "Ex Cathedra" note on this subject in the current issue seems to me calculated to convey the impression that the reversing action of red light is a new discovery. But I distinctly remembrance that the phenomenon was known to the photographic investigators. I fancy, though I cannot be sure, in my present isolation have not the means of assuring myself it was Herschel who first recognised this peculiar reversing action on the photographic record, of red light.

At any rate, I know that at the time of acquiring the information I placed on my agenda list—that long list of so many things which ought to have been done—a suggestion for the following experiment. Over-expose a plate, cover half of it and expose unshielded half for some time to light passing through a monochromator transmitting only the red of the spectrum. Finally, develop the plate with a view to a comparison of the gradation of the two halves. It seemed to me just possible that "red light treatment" might be useful and beneficial in cases of over-exposure as it has proved to be in smallpox convalescence.—Yours faithfully,

Stonehaven, N.B.,

DOUGLAS CARNIE

August 29.

[In regard to photographic surfaces of the Daguerreotype date is certainly true that Herschel observed that red rays exert influence opposite to that of blue rays, and his observations were confirmed by Draper, Lerebours, and Claudet (see Claudet, "Philosophical Transactions," 1847, and the "Phil. Mag.," 1848, XXXII., p. 199). Our paragraph was intended to point out that investigators have of late somewhat disregarded this phenomenon. Eds. "B.J."]

### PHOTOGRAPHING TOMBSTONES.

To the Editors.

Gentlemen,—I have just noticed the query in your issue of August 21, re "Photographing Tombstones," and as I have some difficulty to deal with some years ago, I give result of my experience. The exposure should be made when the sun is shining at a right angle to the face of the stone on which inscription appears—thus, if the inscription faces east, as is usual, the exposure should be made with the sun shining at noon. I remember that, when I took this photograph, there was a discussion on in the "Journal" with reference to that class of work. I sent a note of it, with a print, to the then Editor, who remarked on the distinctness of the lettering. I would have sent a negative, but the negative has gone the way of the "time expired." I am, yours truly,

Clare, Suffolk,

F. STORR

September 1, 1908.

**AFFILIATION OF PHOTOGRAPHIC SOCIETIES.**—A large gathering anticipated at the annual meeting of members of the affiliated societies which takes place at the New Gallery, Regent Street, the courtesy of the Royal Photographic Society, on Friday, September 18. During the evening the 1908 competition slides will be shown.

Arrangements have been made to hold a meeting of Council and district at the house of the Royal Photographic Society on Friday, September 11.

The awards made for prints made on the occasion of the outing are as follows:—First, C. H. Connolly (North London); second, F. C. Boyes (Ilford P.S.); third, J. C. Fox (Staines). The lantern slide award was gained by W. Llewellyn White (London P.S.).

# Answers to Correspondents.

matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

respondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., Wellington Street, Strand, London, W.C.

the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street Strand, W.C., undertake the registration of copyright photographs at a charge of 7d. each photograph, to cover cost of registration fee, form, etc. No unmounted copies of each photograph must be sent with the

## PHOTOGRAPHS REGISTERED:—

Greenway, 27, Abington Street, Northampton. Photograph of the Northampton Town Football Club, 1908-9.

Breach & Co., 37, White Rock, Hastings. Photograph of a Combined Photograph and Drawing of Harry Butt, Sussex Wicket-keeper. Over 1,000 prints in First-class Cricket. Showing Cricket Balls, Bats and Stumps, also a Hand.

1, 28, Queen's Place, Shoreham, Sussex. Photograph entitled: "A Scene in Angling Town, Shoreham, Sussex."

COLOURED BROMIDES.—I am enclosing a coloured bromide print. Do you consider £2 2s. a fair fee to be shown how to get this? 2. Is it an entirely new method?—A. Z.

It depends what business you can do in portrait prints of this type. 2. We do not profess to know what the method is, similar results have been obtained by methods of chemical printing. See the article in our issue of July 24, 1908.

PORTRAITURE.—I should be glad if, through the medium of "B.J.," you could recommend any really good and practical method on posing.—Pro-Pro.

As good as any is "The Pose in Portraiture," in the "Photography" Series. (Messrs. Dawbarn and Ward, 6, Farringdon Road, London, E.C. 6d. net.)

OSCOPIC WORK.—1. What is the best printing medium for stereoscopic work? I am enclosing a few specimens in P.O.P. I use anything better? 2. The prints I am sending are taken from a series taken during my holidays, and having only been taken up stereoscopically I shall be glad if you will kindly let me if they are fairly satisfactory as regards trimming, etc.? You will see, I have cut and transposed negatives. 3. I have a set of apparatus which a friend says is probably some form of stereoscope. It consists of a mahogany board about 3 ft. long, and like the bed of a lathe, into the groove fit three sliders, of which support vertical racks, which would securely hold up photographs, the other one supports a pair of hinged mirrors, which open to a right angle and are apparently intended to set vertically on the board. If, from the above description, can kindly tell me what the instrument is and how to use it I feel obliged.—X.

A grainless surface is necessary to give the best effect, otherwise the printing medium does not matter much. As a general rule a glossy or semi-glossy surface should be selected, as shadows are apt to be lost with matt papers. 2. Your specimens are very good, but you have mounted them rather closely for use in a prismatic stereoscope. The best separation is about  $\frac{3}{4}$  inch for distant objects on the horizon. If no distant objects are in view, then mount so that points in the mid-distance are about 3-16 ins. apart. The trimming is well done, but in one of the views you have not trimmed exactly to the nearest points. In "A View on the Penhill Burn" you should have had the trimming by the overhanging dark branch and taken more off the outside of each picture. In the "Murder Hole" you should have trimmed by the nearest rock. At present the rock appears to be a little in front of the mount, while the dark rock is behind it. A little more off the outside edges would put this right. Altogether, your prints are far more carefully made than we usually see them. 3. Your apparatus is a Wheat-

stone reflecting stereoscope; but in your sketch the mirrors are arranged wrongly. They should be turned round through a quarter of a circle, so that the outside angle faces the observer. The photographs are fixed to the other two supports and placed facing one another at a convenient distance apart. The angle mirrors are arranged between the photographs so that an observer standing in front of the angle sees the right hand picture in the right hand mirror with his right eye, and the left hand picture in the left hand mirror with his left eye. By trial you will soon find the right adjustment. Bear in mind that the images seen are reversed as regards right and left, and that the picture taken in the right hand camera must be the left hand picture in the stereoscope. Either the pictures or the mirrors should slide at right angles to the long baseboard. If you find difficulty in combining the pictures draw both photographs forward a bit or else push the mirrors back.

WORKING-UP.—(1) What is the pure oxide of zinc mixed with, as used by some artists for finishing enlargements? (2) I find the "Crayon Fixatif," as given in the "Almanac," dries in spots and streaks, and yet if I dilute it with more spirit it does not cover up the markings of the crayon. Can you give a formula that will dry evenly and cover up such markings?—CYNDERS.

(1) Most artists use the zinc white, as sold in tubes or cakes by the artists' colourmen. However, if you want to prepare it yourself you must grind it very finely on a glass slab and muller with gum-water and a little glycerine. (2) There is no fault in the formula; it is as good as can be used. Your trouble, we imagine, is due to the way you have used it—not spraying it on evenly, or perhaps to diluting it.

SULPHIDE TONING.—"Sulphide toning solutions should never be kept in a room where photographic materials are stored." Please say if above refers to gold toning solution for P.O.P. made up of gold chloride and ammonium sulphocyanide, as I keep stock toning solution in same press with plates.—J. A. C.

Certainly not. Sulphocyanides are quite without action. Our comment applied only to sulphide.

NEW YORK PERIODICAL.—I wish to obtain a berth in New York or some other large town in United States. Could you give me the name and address of the best American journal to advertise in, also if it would be possible to obtain a berth in U.S.A. by advertising in an English journal?—F. S.

Write to the "Bulletin of Photography," 606-608, Sansom Street, Philadelphia; or "Wilson's Photographic Magazine," 239, Fourth Avenue, New York.

POTASS. PERCARBONATE.—Could you give me a ready way of distinguishing potass. percarbonate from potass. bicarbonate? I have what I believe to be the former, but on immersing in its solution a plate from the fixing bath there is no visible effervescence.—CANTAB.

The percarbonate is a crystalline substance, which readily absorbs water from the air, becoming moist. If a little percarbonate be placed in a test tube and some diluted hydrochloric or sulphuric acid poured over it, there should be evolution of oxygen gas, which can be recognised by its re-kindling the glowing end of a wooden splinter.

W. DRAKE.—We think you cannot have seen the results on all the makes. We advise you to write also to, say, Kodak, Ltd., Birmingham Photographic Company, Ilford, Ltd., Marion and Co., and Rotary Photographic Company for specimen prints. We shall be surprised if one or other of these makes does not suit you.

A CASE OF NOTICE.—I was employed by a firm as an assistant to work at the head business at —; and if necessary to go and take charge temporarily at any of the firm's various branches. I was sent to — to take charge there, and whilst there was sacked. Am I legally entitled to my railway fare back? We have no written agreement.—CYNDERS.

A great deal may depend upon what you were "sacked" for, also, what arrangements you made when you were engaged, as to travelling expenses. These are points that a County Court will decide if you take the case there.

FRILLING.—As we are great users of plates for copying we have lately experienced inconvenience with same, as the film of some comes off when fixing or when washing in water. We do not leave them too long in the hypo or in the water. Also some of the same plates do not fix at all. For instance, last Friday we left some plates in

hypo for about four hours (strong hypo), the white was not off. We left them all night in the hypo, and in the following morning the white was on just the same. We have complained to the manufacturers, and the reply was that perhaps we are using hot developers. We do nothing of the kind. We always use cold developers.—EX.

We are afraid it is not possible for us to assist you, as you do not tell us anything of your working method. It is very rare to find plates frilling nowadays. Possibly the use of freshly made, and therefore chilled, hypo solution may have been the cause. As to the impossibility of fixing out the plates, we can make no other suggestion than that some other chemical than hypo has been supplied to you.

**COMBINATION PRINTING.**—Could you kindly supply me with a little information through the "B.J." as to the following? I have to take a group, size 12 by 10, of members of a club, but they want me to leave a space in the centre of group, and print in one of the heads of the club, to make him a presentation of same. I have secured a photograph of him and they would like to have the group (with him inserted) made without his knowledge. How can I block out same and print his photograph in so as to look as neat as possible? Shall I have to print from the two plates? A little help from you would greatly oblige.—W. E. T.

The method you had best use was described in an article by H. V. Todd in our issue of July 3 this year.

**VARIOUS.**—Please inform me of the uses of the two kinds of "Photometre Loupé"? What I desire to know is if they (either) are useful for interior churchwork? How would their scale compare with Watkins'? 2. In order to harden bromide prints, I use a 5 per cent. solution of formaline. I fix the prints, just rinse or dip in water, then transfer at once to formaline bath. I then wash, dry and sulphide-tone as usual. The formaline bath goes very brown after use. Is it any use for future use, and do I get the prints hard? I do it to prevent blistering.—S. H. C. St. Ives.

1. We are not familiar with Photometre Loupé, and so cannot answer this question. Visual exposure metres such as the Photometre Normal or Heyde's Facile Actino-Photometer are very useful for quick determinations in a bad light, but they require practice. We cannot compare their scales with those of meters such as Wynne or Watkins. 2. The discoloration is, no doubt, due to the hypo carried into the formaline bath. Except that the latter bath may stain the prints when thus altered, there is no objection to your method, though we should prefer to give a five or ten minutes' wash after the hypo. However, the hardening effect of the formaline should not be impaired.

**SERIES OF PHOTOGRAPHS.**—Of a series of photographs I am making one presents a difficulty I cannot see my way through, and to overcome this will be to complete the set. It has occurred to me that such a case may have been presented to you before, and you could offer a little help. My photographs are of local ship-building yards, in each case either taken from the water, or from across docks that are sufficiently wide to allow of the whole length of works to be shown with a water frontage. The photographs are 15 by 7½ taken on 15 by 12, but it is not necessary that I stick to the 15 in., it may be longer, if it has to be in two sections and joined together. All have been got on its one plate, excepting the last one, when the difficulty occurs. They are all very good, and taken with a 16 in. Cooke Anastigmat. The difficult case is where I have works all along one side of a long narrow dock, 150 yards long and about 40 yards wide. If I could get sufficiently far away to get all on one plate, I should not get the water frontage in, and would get buildings in this side of dock I do not want. Thinking I might manage by taking it twice, I made exposures, 50 yards apart, that is, 50 yards from each end of dock, using Cooke 7½ in. Anastigmat which, with care, nearly covers 12 by 10 sharp. You will see by prints enclosed, they will not join. No lens will cover the lot in one exposure, and it will mean 2 or 3 prints to be joined together. In this case I had my lens too low, so got my sky unduly cut off, that can be remedied. As long as I get one long picture whether in 2 or 3 pieces that I can join, it does not matter as to either length or width. Can you help me please in next week's paper?—CENTRAL.

Your difficulty is due to making wide-angle views which cannot

possibly join at the edges unless the subject is one plane. In a subject such as this you must take larger number of narrow angle views and arrange the joins come where there are fewest foreground. You must not have a join in the centre of the crane have now. The subject is a very difficult one as the subject is so short, and we doubt if you can expect a great success. A panoramic camera would probably give a truer idea of the subject. "SAM BUCK," "Old Reader," "G. W. B.," "Printer," and —In our next.

**BLACK BACKGROUND.**—I should be glad if you would kindly tell me, through the medium of the "B.J.," the best and cheapest way to make a black background. I should like, if possible, to have a recipe that will not peel or make black dust afterwards. HUTCHINGS.

The simplest and the best way to make a dead-black background is by the powder process. Full working details of it will be found on p. 155 of our volume for last year. In that whiting and pigment are given, but it goes without saying that for you the whiting must be omitted and the black only employed.

**ENAMELLING PRINTS.**—In your "Answers to Correspondents" column of June 26 last you say, *re* enamelling and emprints: "The enamelling is done in the usual way with collodion and gelatine." We should feel much indebted to you if you would kindly tell us: (1) How are the above solutions prepared and where obtainable? (2) How to proceed with that are to be enamelled — are they squeezed on an oiled glass or on ferrotype plates? (3) As the prints are to be frequently embossed, and are, therefore, to be mounted on thin card or cartridge paper (previous to actual mounting on of emprints with glue to mounts), when are they best mounted thin card so that high gloss does not come off prints when enamelling or after? Would like to obtain results similar to enclosed print, so that detailed information would greatly be appreciated.—ENAMELL.

To answer your different queries in such a way as to be of service to you would take up a full page of the "Journal." Full working details of the method of enamelling prints with collodion and gelatine were published so recently as December (p. 976), we cannot afford space to repeat them here, partly as most readers of the "Journal" are now familiar with them. We must therefore refer you to the article.

**MANITOBA.**—1. A lens with an aperture of  $f/4.5$  is rapid enough for portraiture, though lenses are made with a larger aperture than that. 2. There is no means of diffusing the focus with a lens named. It must be used intact. 3. Yes. 4. There is a lens in the Zeiss list, which has an aperture of  $f/3.5$ , but it is only made up to 12 in. focus. 5. We should advise you to try what you propose, but probably a better result would be obtained by having the magnets rewound to suit the present voltage. We think it would be well to consult an electrician, say one from the company that supplies you with the current.

**B. DOS SANTOS LEITAO (Lisbon).**—(1) Some few of the cameras have been made, but we believe they are not regularly on the market yet. (2 and 3) We suggest that you apply to Mr. Ed. Butler, 26, Craven Park, Willesden, N.W.

\* \* \* **NOTICE TO ADVERTISERS.**—Blocks and copy are received for the approval of the Publishers, and advertisements are accepted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Photographic Salon. A great majority of American work enters the Photographic Salon which opens to-day at 5a, Pall Mall East. The English members of the Linked Ring get a misrepresentation, and other leading pictorial workers practically none. Nevertheless, there is some fine work both as photographic and Autochrome transparencies. (P. 692.) The full review Salon will appear next week.

Printing-frames for colour photography and methods of stereocinematograph projection appear among patents of the week. (P. 692.)

The experimentally minded photographer, a system of making solutions of such chemical strength that a certain volume of equal to the same volume of another is recommended as content in use. (P. 681.)

G. R. Henderson, as the result of his own practice, advises a method of development followed by intensification for getting special qualities in the negatives. (P. 681.)

Describe the working of a paper for the production of direct prints in the camera. The results resemble good collodion prints. (P. 681.)

Comprehensive paper, contrived a year or two ago by Mr. C. R. Piper to a Continental journal, is reprinted on page 694, the reason that it provides the exact rules required for the practical correction of distortion and for the construction of apparatus in which such correction can be carried out.

## EX CATHEDRA.

### Rapid Bromide Printing.

The provision of one or other of the hand-fed printers may be said to be a necessity in turning out bromide work in any quantity. The use of an ordinary printing-frame is altogether too wasteful of time. Certain printers have the advantage that they can be used in the dark-room close at hand where developing is being done, since there is no escape of white light from the apparatus. A rough and ready but practical method of attaining the same end is to arrange a lamp and switch on the work bench, placing it in a box built from four printing-frames, which form vertical walls round the lamp, a fifth printing-frame being laid in position to form the top. This device is sufficient to make it unnecessary to cover up sensitive cards or paper, but it naturally requires that the negatives should be of equal printing speed. A device which can be easily extemporised, and is in some respects more convenient than a printing machine, consists of a box fitted under the dark-room bench. The top of the box is formed by the work bench, or rather an aperture is cut in the latter, and the box fitted therein. The aperture being glazed, and provided with a hinged cover, the negative is laid on the glass and the paper pressed into contact by the cover, which is readily adjusted to switch on the lamp.

### A Novel Society Programme.

As typical of a number of letters which have reached us in reference to our paragraph last week on the photographic society programme, we insert that from the president of the Edinburgh Photographic Society in another column. The secretary of the Blackburn and District Camera Club has sent us the programme of his society, which takes the somewhat novel form of a wall placard with a tear-off list of fixtures attached. Members thus have the proceedings of their association kept prominently before them, and in addition are offered prizes for prints which may most suitably fill a space provided for the purpose in this novel society programme.

\* \* \*

### The Use of Pinholes as Stops.

The Rev. F. C. Lambert a long time ago pointed out that by taking advantage of the great depth given by very small stops it is possible to use a short focus lens as a long focus one, and vice versa, which means that the same lens can be used at a wide or narrow angle at will. Of course, this involves the use of very small stops, of about the intensity of  $f/100$  to perhaps  $f/150$ , and proportionately long exposures must be given, but the expedient is a very useful one at times. Even at  $f/64$  (generally the smallest stop available) a little can be done in this direction. If using Waterhouse diaphragms it is, however, an easy matter to

Provide extra ones with the required small apertures, but the iris is the usual form nowadays, and with this a special device must be adopted. There is no great difficulty in providing a perforated metal disc that can be inserted in the lens mount against the partially closed iris. When a doublet is used and a longer focus is required, the usual expedient is to remove the front combination and work with the back one alone. This often requires a longer camera extension than is available, and the pinhole stop may then come in useful to shorten the working focus of the single lens and render it serviceable. To shorten the working focus of a doublet, of course the front combination must be replaced when the stop has been inserted. It will be found in practice that a stop of about  $f/150$  gives a big latitude of movement, and that a 6-inch lens, for example, may be made to serve the purpose of any lens of between 4 and 10 to 12 inches. The exposures are, of course, long, and can be regulated in much the same way as those for pinhole work, but the definition is much finer than that given by a pinhole if the variation in extension is not carried to extremes.

\* \* \*

#### A Useful Experimental Device.

On another page we review a new book by Mr. A. M. Worthington entitled "A Study of Splashes," and we draw attention to the very simple and effective method adopted by the author for making his successive exposures at very short intervals of time. The problem that he had to solve in devising his apparatus was not a simple one by any means, yet one of a kind that many photographic experimenters have to tackle. Briefly, it may be stated thus:—To obtain photographs of a falling drop or ball at intervals of one-thousandth of a second. It being obviously impossible to take such exposures in succession during one fall of the ball, the apparatus had to be reset for every exposure, and the period between the release of the ball and the exposure had to be increased by one-thousandth of a second for each exposure. The method adopted was to use two balls dropping simultaneously. One ball in dropping passed between two terminals, and so completed an electric circuit, and this caused a spark that served to illuminate the other ball. By the simple expedient of dropping the timing ball from a greater height every time the period before the exposure was increased at the rate desired. This arrangement gave an accurate and easily adjusted time regulation, for a fairly considerable rise was required to increase the time even by such a short period as one-thousandth of a second. For example, if the height of fall down to the terminals be increased from 4ft. to

4ft. and two-fifths of an inch, then the time of fall is increased by just one-thousandth of a second. This is a device that can often be made to serve a useful purpose. The manner in which the falling ball completes the electric circuit is also a useful expedient worth special notice, for when the photographer attempts to regulate the completion of a circuit by the aid of a falling body, seldom has any better idea than that of allowing the weight to hit, and probably break, something.

\* \* \*

#### Very Short Spark Exposures.

A very bright light of very short duration is another thing often required by the photographer for special work, and Mr. Worthington's method of securing this is well worth noting. He uses two large Leyden jars, and charges the inside coating of one positively and the inside coating of the other negatively, with the aid of an ordinary electric machine. A Wimshurst machine is, of course, the best, but the old-fashioned and cheaper cylinder could be used. From the outside coating of each jar a stout wire is taken to the point where the light is required, and the ends of the two wires are armed with magnesium terminals, a set so as to leave a suitable spark gap. On connecting the inside coatings of the two jars, which connection is made in Mr. Worthington's experiments by the falling ball, a brilliant spark of extremely short duration passes the magnesium gap, and the exposure is made. The duration of this spark was found to be less than three-millionths of a second, whereas the spark given by an induction coil covers a very much longer period, and, in fact, gives much too long an exposure for such purposes as Mr. Worthington had in view.

\* \* \*

#### The Workroom Floor.

Excellent as is the cemented or tiled floor of a printing-room or dark-room from the point of view of cleanliness, it has drawbacks in other respects which may be worth consideration, since they affect the economical working of the establishment. Such floors are very cold to the feet, and unless the rooms are very well warmed, long spells of work such as are necessary before Christmas, may make the worker so miserable that he cannot do his work properly even if they do not induce worse symptoms. A much preferable form of support for the feet is a wooden rack, made of stuff 2 inches by 1 nailed on 1 inch cross-pieces with 1 inch between each board. These gratings are very warm and dry to the feet, and being raised from the floor and movable are a great help to cleanliness in the workroom.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1909.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-eighth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of over 1,000 pages, and the entire edition of 25,000 copies was sold out immediately. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1909 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

#### REFLEX CAMERAS,

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1909 will be

modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1909 will appeal to photographers the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and, wherever practicable, new features of an informative nature will be added.

**\*\* IMPORTANT NOTICE.**—The attention of advertisers is specially directed to the announcement that the entire edition of the ALMANAC (25,000 copies) will again be placed in the hands of dealers and the trade on December 1, as to be well in advance of the Christmas publishing season, and the co-operation of advertisers to that end will be esteemed by the publishers.

# EQUIVALENT SOLUTIONS FOR EXPERIMENTAL PURPOSES.

My article on recording the results of experiments were some simple hints intended for the benefit of the amateur investigator. Another hint that may be of service is the advice to prepare his testing and experimental solutions on what is known as the equivalent system. For the majority of his work this may not be a matter of great importance, but occasionally it is of very importance, and a great saving of time and trouble is effected if the properly adjusted solutions are to be used. To give a simple instance: it is often desirable to repeat an experiment made on, say, a chloride emulsion on paper, upon a preparation of simple silver chloride. The ordinary way silver nitrate and hydrochloric acid and sodium chloride will be at hand in solutions of various strengths, and when the experimenter comes to prepare a chloride he will have to make sundry calculations to find out how much of each solution he must take. If he is a careless worker he will probably jump to conclusions, and use too much of one of the ingredients, and not only waste material, but probably spoil his experiment, for it is somewhat a matter of considerable importance to avoid an excess of one of the ingredients. If equivalent or "normal" solutions are at hand, all he has to do is to take equal parts of them to obtain the product he wants, and an excess of one ingredient is necessary, a few extra drops will provide it. A so-called "normal" solution is one in which one litre of solution contains exactly the gram equivalent of the active reagent weighed in. Generally such a solution is too strong, therefore solutions of one-half or one-tenth that strength are used, called seminormal or decinormal solutions. The following table gives some of the most useful solutions in their proper strengths, but for general purposes these can be used to decinormal strength. A certain quantity of any solution here given will exactly neutralise an equal

quantity of any of the alkaline solutions, and if a halobromide salt of silver or copper is required, equal parts of the solutions will produce it. When used as test solutions the amount of the test solution required, of course, affords a measure of the quantity of the substance tested for, which fact is the basis of volumetric analysis. The figures in the table are the number of grammes that should be taken to make the litre of normal solution.

Hydrochloric acid .....	36.537	Iodine .....	126.5
Nitric acid .....	63	(with 180 grs. pot. iodide)	
Sulphuric acid .....	49	Potassium bromide .....	119
Ammonia .....	56 cc.	„ iodide .....	166
(use ammonia .880)		Silver nitrate .....	170
Ammonium bromide ..	98	Sodium chloride .....	58.5
Barium chloride .....	121.77	„ carbonate (dry) ..	53
Copper sulphate .....	249.5	„ hyposulphite ..	248

In making the normal solutions of acid and alkali it is best to make a solution of soda carbonate first, using pure carbonate that has been previously heated and allowed to cool, and weighing it out very carefully. This may be taken as a standard correct solution, and then the acid solutions can be checked against it, using methyl orange as the indicator. The normal sulphuric acid of 49 grams to the litre will be arrived at very nearly if 30 cc. of pure sulphuric acid of S.G. 1.84 is mixed with about 150 cc. of water, and when cool is diluted to 1 litre. An approximately accurate normal solution of hydrochloric acid is made by taking 181 grammes by weight of acid of S.G. 1.1 and diluting to 1 litre. The nitric acid solution should be made from colourless acid of S.G. 1.4. The ammonia solution keeps best in a half-normal strength—that is, 28 cc. of .880 ammonia should be diluted to 1 litre. One of the acids should be regulated by testing against the carbonate, and then the ammonia should be tested against the acid. In volumetric analysis it is, of course, necessary to adjust the solutions very carefully, and as exact equivalent adjustment is nearly impossible, the errors are determined and allowed for. For work of the kind that we have in view in this article it is not necessary to be so minutely exact. The point we wish to insist upon is the great convenience of using solutions made up on the principles of the equivalent system.

## A RELIABLE METHOD OF DEVELOPMENT.

Some time ago several of the photographic journals gave an account of a "modern" method of developing exposed plates by treating them with an alternative bath in what might be called No. 1 and No. 2 solutions. This so-called "modern" method was practised many years ago by a photographer of my school, whose photographs of architectural subjects were the despair of all who saw them. But whereas the adherents to the method advocate metol, pyro-soda, and the like for the purpose, my old friend used the ever-popular pyro-ammonia formula. I have for the last four years or so used his method, but with a slight modification in the proportion of the developer. Pyro-ammonia is perhaps the best *par excellence* for all work where differing textures of materials and flesh are to be faithfully represented; yet, in this, it is not used so extensively in everyday work as the other qualities justify. If it were only on the score of cheapness and detail-giving properties, this developer would be permanently housed in all dark-rooms. I am well aware of the fact that many photographers have failed to make good use of it, but I am afraid their efforts have been misdirected when they failed to make good negatives with

pyro-ammonia. As in the case of other formulæ, its peculiarities must be thoroughly understood. There are several ways in which pyro-ammonia may be successfully used, and even to the "alternative" method there is yet another alternative.

In explanation, I may as well describe my own way of using it. First, then, I make my pyro solution by dissolving 1 oz. of metabisulphite of soda in 7 oz. of water. I then pour this mixture into a bottle containing 1 oz. of Schering's pyro. When thoroughly dissolved, the solution is made up to 10 oz. with water. This forms a stock solution of pyro, from which 300 minims are taken and water added to make 10 oz., making the No. 1 working solution. The No. 2 working solution is made by dissolving 15 gr. of potassium bromide in about 7 oz. of water, adding 70 minims of ammonia .880, and making up to 10 oz.

As mentioned above, there are two ways of using these solutions successfully. Assuming that the plate has received an exposure sufficient to impress the shadow details thereon, the method to adopt is to allow the plate to soak in No. 1 solution for four minutes and then to transfer it, without washing,

The No. 2 solution for a similar period. The resulting negative will be a soft one, full of quality and detail, and entirely free from that bugbear, dichroic fog. The second plan is perhaps even better, and is the one I myself use successfully. Exactly the same solutions are used, but the plate is allowed to stay in each for only one minute. Fixing follows in the usual way, and the result is a thin negative, with perfect detail and exquisite gradation in the high-lights and shadows. For up-to-date printing processes it is very little use in its present condition, but a little manipulation will change all that. If the negative shows a slight veiling of the shadows, as it probably will do, it must be treated in a clearing bath made up as follows:—

Alum .....	2 oz.
Citric acid .....	1 oz.
Water .....	10 oz.

A few seconds' immersion in this bath will be found sufficient; and I may here mention that I always use this bath, as I find that subsequent operations are more easily carried out when the negative is cleared in this way. After a slight washing,

the negative is transferred to the following intensifying solution:—

Mercuric iodide .....	15 gr.
Soda sulphite .....	300 gr.
Water .....	3½ oz.

In a few minutes the negative will have attained sufficient density, and a solution of sodium sulphide (5 per cent.) should be applied for a few seconds. After washing—for not too long a time—the negative is complete. Batches of plates may be treated in this manner, and the saving of time over ordinary methods is considerable. A remarkable point to be noted is the total absence of halation, even when most expected. When dealing with interiors and portraits with drapery this quality is invaluable. I have experimented with various formulæ, but I have never been able to obtain such exquisite negatives as with the foregoing formula and method of working. I have often been asked by friends how I managed to get such brilliant effects and yet retain the softness so desirable in portrait work. The answer is here given for the benefit of the profession at large.

G. R. HENDERSON.

## THE GERMANO-AMERICAN SALON.

A PRELIMINARY look round at this choice and not too hardy annual reveals some interesting facts. We find the number of prints lower than ever, chiefly because the walls are for the most part occupied only by a single line of works. But let not the eager visitor imagine that he is to see a choice selection of the work of all his old Salon favourites. What he will see is a liberal selection of the work of a small handful mostly of newly forged links. The long wall to the left upon entering the R.W.S. gallery is furnished by a long line of Arbuthnots and De Meyers, with a little central group of Parisian oils bunched up in the middle. The small angle wall next, contains a clump of Beningtons. The north end wall is Coburn territory. The next angle wall has a handful of things, including a Mrs. Coburn, a single Evans, and a single Blake. The longest wall, after dallying with one Cadby, one Mrs. Cadby, and an Evershed, becomes more liberal with two Mrs. Brigmans, three Miss Blands, four Keighleys, ten Eugenes, ten Steichens, six Stieglitz and Whites, and ten Whites, and then tails off to a few general examples, seven in all. The south wall has three Mortimers and eight Craig Annans. The rest is a little general smattering, including one Craigie and one Keighley.

The middle of the room displays some excellent Autochrome in an erection furnished with eaves to shade the spectator and supplied within with a long gable of metal foil at a proper angle to transmit reflected light through the plates. The Autochrome section is important, and offers some first-rate work. There are two Craig Annans, eleven Coburns, twenty De Meyer (at twenty guineas apiece), a G. B. Shaw, which, by the silence of the catalogue, must be judged either priceless or worthless twenty-nine Steichens, and three Warburgs.

It will be seen that the exhibition is a Coburn show primarily, a Steichen show secondarily, a De Meyer show tertiarily. It will also be seen on reference to the catalogue that these gentlemen were active upon the selecting committee, and we may add upon good authority that the names of the other acting selection committeemen were Arbuthnot, Benington, Davison, and Keiley, though the latter's name is not printed as such. Mr. Craigie should have acted, but came rather late. We deduce that if a link wants a good show for himself he must be upon the selecting committee in the first place, and in the second place he must be an early bird upon the scene of action if he would find even the mangled remains of the proverbial worm.

## PORTRAIT PRINTS DIRECT IN THE CAMERA.

It may be remembered that some weeks ago we mentioned the so-called "Positype" process for the production of single positive prints as the result of direct exposure in the camera. Since then we have had the materials in our hands and have been able to obtain results in every way equal to those previously shown us as examples of what the process would do. The new method certainly is deserving of the attention of professional photographers, by whom its rapid production of a permanent photographic portrait may be utilised advantageously in various ways. But before touching on the process itself, we will first explain the principle of the method, and then go into details as to the practical working.

The "Positype" paper is evidently coated with an emulsion resembling that of bromide paper, though evidently also differing from this latter in some particulars. A finished result in the

way of a positive print is not, however, obtained as it was in the old glass positive days, and still is by means of the ferrotype picture; that is to say, by producing a negative image on a dark background, and, by suitable choice of developer, making this negative image of a whitish appearance. This old method of preparing a positive, excellent as it is in skilled hands, can never be a really popular process now that few persons are experienced in the wet-plate process. In the "Positype" process, an equally ancient method is employed; yet for the first time, so far as we know, in producing a really excellent photographic print on paper. The method is, in fact, nothing more than the reversal of the primary negative by a series of operations which are very similar to those conducted with the same object on the Autochrome plate. In other words, the negative image is dissolved away, and the residual (positive) image rendered visible.

suitable method. There is one reason why this method is particularly suitable for a process which is designed for the production of prints in a short space of time—there is no need to wash and therefore there is no washing out of hypo to be done. A feature is a strong point in favour of such reversal processes adapted for "rapid photography." The print, too, is a really fine photograph, and not something made to look like a fake by a species of trickery.

Following the directions given for the use of the "Positype" paper, the paper, after exposure as for a plate of "medium" quality, is developed up to a point at which the image (negative) is somewhat overdone, when looking down upon it in the developing dish. For this purpose two developers are given, one so-called "slow-acting," and another described as "instantaneous." The formulæ for these latter are as follows:—

#### SLOW-ACTING DEVELOPER.

Soda sulphite dry, pure .....	1½ ozs.
Potass. carbonate .....	1½ ozs.
Hydroquinone .....	180 grs.
Potass. bromide .....	40 grs.
Water .....	20 ozs.

#### INSTANTANEOUS DEVELOPER.

Soda sulphite dry, pure .....	2 ozs.
Water .....	15 ozs.
Caustic potash stick .....	1½ ozs.
Potass. oxalate .....	2 oz.
Potass. bromide .....	140 grs.
Water .....	5 ozs.

Mix the above, mix A and B, and add:—

Hydroquinone .....	1 oz.
--------------------	-------

As our trials have gone, this latter developer gives as good a result with considerably less exposure; it certainly acts much more quickly, which is in itself an advantage for portraiture where you wait."

Development lasts about two or three minutes. The print is rinsed under the tap for an instant only. It is then put one minute in a solution of sulphite of soda (1 oz. in water). It is then given a further wash of about one minute under the tap before placing in the "bleaching" or "reversing" solution. This is supplied for the Positype process under the name "Blanchite," and, from its yellow colour, would appear to be a bichromate preparation. Therefore, while no real harm results from any sulphite which remains in the print, the intention will be to destroy the "Blanchite," and for this reason washing should be fairly thorough. A minute, or no doubt under the spray jet should be ample.

The "Blanchite" acts very quickly; half a minute suffices to remove all traces of the image save a faint brown trace. As at this point is reached the light can be turned up in the dark-room, and the remaining operations done by either daylight.

After a short rinse under the tap from the "Blanchite," the print is placed for one minute in soda sulphite solution (1 : 8), and for this purpose a dish of solution different from that used

after development. In this bath the yellow tint of the "Blanchite" is discharged, and all that now remains is finally to tone or re-develop the print in one or other of the two solutions provided for the purpose—viz., "Septone" or "Nigro-tone." The result in the respective cases is a print of rich sepia colour or of warm black. Either solution acts in less than a couple of minutes, and a final rinse in clean water then completes the process. From their odour the two solutions "Septone" and "Nigro-tone" evidently contain sulphide or a similar body, but must be combined with other constituents, which act differently on the silver bromide image.

In order to take a glance over the succession of operations, we may, from the above directions, prepare a time-table of the process:—

Development in "instantaneous" or "slow" solution—2 to 3 minutes.

Washing under tap—½ minute.

Soaking in soda sulphite, 1 in 8—1 minute.

Short washing under jet—1 minute.

Treating in "Blanchite," 1 in 10, with rocking until image disappears—1 minute.

Washing—1 minute.

Treating with sulphite, 1 in 8—say 2 minutes.

Treating with "Septone" or "Nigro-tone," washing and drying off—5 minutes.

This table gives a total time of 13½ minutes for the making of a print, and 15 minutes, or 20 at the most, should be ample time in which to have a print in readiness after entering the dark-room, and this without leaving anything to chance as regards permanency.

Apparently the Positype paper is not made with gelatine emulsion; at any rate, the surface can be dried with perfect safety by aid of moderate heat, and gives a print with a surface best answering to the description of "semi-matt." It is not distinctly matt or glossy, but of the dead-fine character usually given the above description. As to this, however, a sample print of the paper, doubtless obtainable from the agent for the process, Mr. Charles Dawson, Holloway Hill, Godalming, is a better specification of the prints than any form of words.

As regards the use of the paper, the most obvious application is for photography of the while-you-wait order. For this, as we have already said when first mentioning the paper, the really handsome appearance of the prints is altogether too good. It is possible, of course, that the taste of persons patronising this order of photographer may be capable of elevation, but we doubt it. At any rate, for such occasions as bazaars, soirées, etc., a "Positype" portrait studio should be a source of profit, and the speed of the paper should be just about sufficient to permit of exposures by arc light.

The cleanness of the process should also render the paper useful for the making of enlarged negatives direct, although the emulsion for this purpose would have to be coated on a much thinner paper than the specially stout stock which has been used for the paper we have employed.

**FRIDAY BOOKLETS.**—The latest additions to the series of booklets published by the St. Catherine Press, Ltd., of 8, York Buildings, E.C.4, W.C., deal with the districts of Banff, Crediton, Farnham, and Kingsbridge and Salcombe. They contain much useful information for the guidance of the visitor, and copies may be had, post free, by applying to the Town Clerks of the respective districts.

**RIGHT TO ONE'S FACE.**—The "Conversations on Copyright," which have been published in the "British Journal" (writes "Sharn-Newton Zealand Photographer") explain very fully the law and the right of copyright in "the Old Country." A fact which comes out of the evidence is that there seems to be no remedy against a photographer who makes or publishes a libellous caricature of

well-meaning but unconscious citizens, by sudden "snaps" upon their persons. In New Zealand the public are protected against the camera fiend by the proviso that the photographer shall not print or publish portraits of persons or groups of persons without their express consent.

By the way, in the registration of photographs and works of art under the New Zealand Copyright Act, the cost is scheduled at one shilling for the form and a half-crown fee for registration; to this the registrar now adds five shillings for the certificate of registration. Surely this last payment might be suspended until the certificate was actually required, since a total payment of eight shillings and sixpence each makes a costly luxury of the legal protection of numerous works of small value.

## TONING, INTENSIFICATION, AND REDUCTION.

[In the following article in "Photo Notes" Mr. Morison describes several methods of intensification dependent on sulphiding process. It will be seen that he uses a mixture of a developer and of a sulphide that some readers may like to experiment with. If a developer alone were to be used, then bleaching solution No. 1 would of course give far more density than No. 2. In sulphide toning, No. 1 generally gives a darker colour than No. 1, but we doubt if it can give a greater printing density in any circumstances. We should be inclined to reverse the order of these two solutions.]

MANY readers are aware of the process of bleaching and blackening or sulphiding an image as a means of intensifying negatives, etc., but I think few are aware that the ordinary processes of bleaching and blackening have many variations. I have endeavoured in the following article to explain fully some of them. The processes detailed consist of a reducer for strong contrasted negatives and prints, and intensifiers for different degrees of intensification which are also of use for toning bromides all shades of brown. In the first place the bleaching solutions are put forward in the order of intensity in the finished result.

Starting with the lowest :—

### No. 1.

Potash bichromate .....	2 parts.
Hydrochloric acid .....	1 part.
Water .....	100 parts.

### No. 2.

Potass ferricyanide .....	10 grains.
Potass bromide .....	10 grains.
Water .....	10 oz.

### No. 3.—Extreme density for line-work negatives.

Lead nitrate .....	40 grains.
Potass ferricyanide .....	60 grains.
Acetic acid .....	18 mins.
Water to .....	2 oz.

After bleaching with No. 3, wash carefully once in 10 per cent. nitric acid, then in water.

The following darkening solutions are also in the order of intensity beginning with the weakest :—

A. Rodinal .....	20 to 30 drops.
Sodium sulphide saturated solution .....	30 drops.
Water .....	2 oz.
The more rodinal the less increase of density.	
B. Schlippe salts .....	1 part.
Ammonia (25 per cent. sol.) .....	1 part.
Water .....	100 parts.
C. Sodium sulphide .....	1 oz.
Water .....	100 oz.

With the use of No. 1 as a bleacher and A as a darkener very little intensification, or a nice warm black on bromide paper.

B instead of A gives a light reddish brown, C a dark brown.

Then also we can use No. 2 as the bleacher and darken with C, while the use of No. 3 and C together gives a very strong only suitable for line work.

To reduce harsh contrasts on negatives, or bromide, gaslight P.O.P. prints (fixed and washed only) bleach in No. 1 or 2 and develop with rodinal 1 part, water 50 parts. When development reaches the density wanted, wash and transfer to an ordinary bath. The action of the developer proceeds evenly through the so that the thinner parts are developed first and so on in rotation the image has acquired its original density; therefore it will be that we can stop at any density. The fixing bath, of course, solves out the remainder of unaltered salts. P.O.P. prints toned after this treatment.

## THE CORRECTION OF DISTORTION PRODUCED BY TILTING THE CAMERA.

[As the rules on which is based the correction of the distortion particularly in the design of copying cameras and other apparatus the papers contributed by Mr. C. Welborne Piper to the now defunct "B.J." some years ago, but the following article is the only

produced by tilting the camera are of considerable interest, serving for the preparation of undistorted copies, we reprint the "Camera Obscura." A preliminary paper on the subject appeared one containing a full treatment of the question.—Eds. "B.J."]

WHEN the camera is tilted for the purpose of bringing the upper portion of a high building on to the plate, a distorted image is produced if the plate holder is not swung forward into a vertical position. Such distortion cannot always be avoided, but, under certain conditions, the image can be afterwards corrected by a process of copying.

In this article I propose to consider only the nature, amount, and correction of the distortion produced with the plate holder fixed at right angles to the principal axis of the lens, the swing back not being used at all. It is unnecessary to study the more complicated problems relating to the misuse of the swing back.

### The Nature of the Distortion.

Instead of a high building we will assume the object to be a plane rectangular diagram pinned to a vertical wall at some distance from the ground, this being a general case that will cover all possible cases. In figure 1 the object is shown in vertical section at DE. The camera is in front in position 1, and is tilted so that the principal axis of the lens is directed towards the approximate centre of the object, or to the point P. The vertical plane in which the principal axis lies is supposed to be at right angles to the wall. The angle of tilt of the camera is represented by the angle A1, which is equal to the vertical angle A2 between the object and a line normal to the principal axis, or the inclination A3 of the camera-back from

the vertical, when the back remains at right angles with the principal axis.

Suppose now we take two photographs of the object, one with the plate adjusted vertically, as at I J, and the other with the back

Fig. 1.

right angles to the principal axis, as at GK, preserving sharp focus at the point P in each case. The former is then a correctly proportioned image of the plane object, and the latter is a distorted image

as both are on the same scale of reduction, the second image may be looked upon as a distorted copy of the first on a scale of equal size. Little consideration will show that if we tilt the camera to a certain angle from the horizontal when taking a vertical object, the result is identical with that which would be produced if we kept the camera level and inclined the object to the same angle from the vertical, and this forms the most convenient method of representing the effect of tilting the camera.

In figure 2 the object is represented in vertical section by the line

Fig. 2.

the principal axis of the lens by the line PLQ, the lens being at L, and GQK represents the plate in a position normal to the lens. If the camera-back is swung to the position IQJ, parallel with the plate, a correct image is produced, but with the back in the position K we have a distorted image. The tilt of the camera is represented by the inclination of either DPE or IQJ from the vertical, and is by the angle marked A, which letter throughout this article represents the angle of tilt under which the distorted negative is taken.

Figure 3 shows in elevation the correct image produced with the camera level, and over it the distorted image produced by the swingback in thick dotted lines, and over it the distorted

Fig. 3.

image is drawn in full lines. The point Q corresponds with Q in figure 2, and the horizontal line SS, passing through the point Q, divides both images into upper and lower portions.

The most prominent characteristic of the distorted image is its horizontal distortion, by reason of which the sides in the lower half diverge downwards, and in the upper half diverge upwards, the width being correct only on the line SS. There is, however, also vertical distortion; the height of the lower part of the image is increased, and that of the upper part is increased, while the total height is too small. These conditions are those most likely to be met with in practice, but they are not invariable. If the distance from the lens to the object in figure 2 is considerably shortened without altering the angle of tilt, the total height of the distorted image will be greater than that of the correct image; while if PL is increased beyond a certain distance, equal to PE cot.  $\frac{1}{2}A$ , the height of the upper part of the image will be dwarfed, not increased.

If, however, the camera stands on level ground an increase of distance between object and lens necessitates a less angle of tilt, as shown in position 2 in figure 1, and, as a diminution in this angle increases the value of PE cot.  $\frac{1}{2}A$ , the special condition is not likely to be fulfilled. The distance PL can only be increased without altering the angle A, or independently of the value of PE cot.  $\frac{1}{2}A$ , when the ground slopes from the object at an angle from the horizontal equalling the angle of tilt, that is to say, when a movement of the camera from the object necessitates a retirement down a hill of a certain gradient, as shown in position 3. This condition being exceptional one, some, judging only from distortions produced by the camera, have come to the erroneous conclusion that the upper part of the image is necessarily always increased in height. The effect of horizontal distortion diminishes as the distance PL (figure 2) increases, hence, at an extreme distance convergency

practically disappears, or the width of the image is apparently correct at all parts, while the total height is dwarfed to a minimum. In such a case varying heights are all reduced proportionately, so that though all are dwarfed they are relatively correct compared with one another. We may consider vertical distortion to be productive of two distinct effects. Simple vertical dimensions may be exaggerated, dwarfed, or correct, while different vertical dimensions may be correct or incorrect in their ratios to one another. Suppose, for example, the object is a chessboard. If the principal axis of the lens is directed towards the centre, the upper and lower halves of the object are each divided into four equal heights. Let each height equal H, then, in the upper part of the image, the total height is correct when the distance of the camera from the object =  $4H \cot. \frac{1}{2}A$ , all lower heights being dwarfed. The total height of three squares is correct when the distance =  $3H \cot. \frac{1}{2}A$ , but the height of four squares is then excessive, while that of two is dwarfed. Only one dimension is correct at any one particular distance, and therefore the various heights of one, two, three, or four squares are relatively incorrect.

When the distance exceeds  $4H \cot. \frac{1}{2}A$  all heights are dwarfed, and none are correct, either absolutely or relatively, until the distance approaches infinity, when all absolute heights reach a minimum, but are relatively correct.

In the lower part of the image heights are dwarfed at any distance and are relatively incorrect until the distance PL reaches infinity.

### The Measurement of the Distortion.

The vertical and horizontal dimensions of either the upper or lower portions of the distorted image can be calculated from the following formulæ, all heights being measured vertically, up or down, from the horizontal line marked SS passing through Q in figure 3, and all widths being measured at the level reached by the vertical dimension. With an irregular plane object widths would have to be measured on either side of a vertical line GQJ passing through Q, the whole image being considered to be divided into right and left upper, and right and left lower quarters. A symmetrical rectangular object, such as that under consideration, need only be divided into upper and lower halves, and the widths may be taken right across the image.

In these formulæ the dimensions of the distorted image are given in terms of the corresponding dimensions of the correct image on an equal scale, shown in figures 2 and 3. The size of the correct image can, of course, be easily ascertained from the dimensions of the object and the scale of reduction, and the scale of reduction can be arrived at by comparing the length of the non-distorted line SS in figure 3 with the corresponding dimension in the original.

Each half or quarter image being considered separately, let

H = vertical height of distorted image above or below point Q; = GQ or QK in figures 2 and 3.

h = corresponding height of correct image; = IQ or QJ in figures 2 and 3.

W = either half or complete width of distorted image at level reached by H; = GG or KK in figure 3.

w = corresponding width of correct image; = II or JJ in figure 3.

v = distance from lens to image; = LQ in figure 2.

A = angle of tilt; = MIQ in figure 2.

We then have,

1. In upper part of image

$$H = h \cos A \frac{v}{v - h \sin A} \quad (1)$$

$$W = w \frac{v}{v - h \sin A} \quad (2)$$

H is greater than h when v is less than h cot.  $\frac{1}{2}A$ .....(3)

2. In lower part of image

$$H = h \cos A \frac{v}{v + h \sin A} \quad (4)$$

$$W = w \frac{v}{v + h \sin A} \quad (5)$$

H is always less than h.

The amount of distortion depends actually on the angle of tilt, the distance of object from lens, and the size of object, but in the equations the distance of image from lens and size of correct image are substituted for the second two factors.

The manner in which these formulæ are arrived at is apparent from figure 2, for, considering the upper image only, if we draw IM vertical to LQ, then GQ:IM::LQ:LM, and, width at G: width at I::LQ:LM. Equation 3 is found by considering the special case when GQ=IQ.

### The Correction of the Distortion.

Suppose now we have a distorted negative, such as we have been considering, and endeavour to produce from it a correct positive copy in the camera; keeping the negative in its original inverted position, and making all adjustments tentatively. We find that we can correct the horizontal distortion, or convergency, alone, in an infinite number of ways. A cure is effected if we incline either the copy or the negative or both together to certain angles; but only when the two are inclined in opposite directions to particular angles is it possible to also secure sharp focus in all parts of the copy. Next, we find that height is increased or diminished, according as we incline the copy away from or towards the negative, or the negative to or from the copy; and, while a number of positions may be again found in which height alone is corrected, there is only one in which both height and convergency are corrected. This position is difficult to find exactly, and further it most probably is not the position in which sharp focus is also secured.

If we repeat these experimental adjustments with the lens at a different distance from the negative, that is, try the effect of copying on a different scale, it will then be found that the angles at which correct width and focus, or correct width and height are secured vary considerably from the former results; hence, it is apparent that with any particular lens the scale on which we copy is an important factor. It is difficult to make these tentative adjustments when both negative and copy require to be arranged simultaneously, and it is practically impossible tentatively to hit off the exact adjustments essential to securing correctness of height, width, and focus.

### Data Essential to Correction.

Referring to equations 1 and 2, or 4 and 5, it is evident that the proportions of the correct image, or the values of  $w$  and  $h$ , can be calculated if we know the values of  $A$ ,  $v$ ,  $W$ , and  $H$ .  $A$  and  $v$  were presumably recorded at the time of taking the original negative.  $H$  and  $W$  can be measured from the distorted image if the point  $Q$  (figures 2 and 3) is recorded. The factors necessary for the calculation of the correct image are also necessary for its reproduction in the camera, and by directing the axis of the lens used for correction on to the fixed point  $Q$ , we keep  $H$  and  $W$  constant in value, while the recorded values of  $A$  and  $v$  have to be considered in making the other adjustments. The correction process, however, introduces a new factor. The original distance between the lens and the negative cannot well be preserved, and therefore a new variable factor,  $V$ , must be considered. To exactly determine the conditions of correction we must then keep the lens axis directed to the point  $Q$ , and pay regard to the values of  $A$ ,  $v$ , and  $V$ . It is obvious that  $V$  will vary with the focal length of the lens and the scale on which we copy.

### Explanation of Figures and Formulæ.

In figure 4 we have a diagram constructed similarly to figure 2, but showing the distorted negative GQK and the corrected copy d p e inclined in opposite directions, which is a condition essential

Fig. 4.

to the attainment of sharp definition. The lens is at  $l$  and  $pl$  is the lens axis. Draw  $IQJ$  parallel to  $dpe$ . It is then apparent that  $IQJ$  is a vertical section of a correct image similar to  $dpe$ ; and, further, if  $GQK$  in figure 4 corresponds with  $GQK$  in figure 2, and the point  $Q$  in figure 4 corresponds with  $Q$  in figure 2, it is evident that the corrected image  $IQJ$  in figure 4 corresponds in all respects with the correct image  $IQJ$  in figure 2, and may be looked

upon as a corrected copy of the distorted image on a full size scale. If therefore we presume  $IQJ$  in figure 4 to be a corrected image,  $IQ$  must be equal to  $IQ$  in figure 2, and the width at  $I$  must be the same in both cases. Therefore,  $H$ ,  $h$ ,  $W$ , and  $w$  have the same value in figure 4 as in figure 2.

In figure 2 the different points of the diagram are marked in capital letters. In figure 4, lines that remain of the same length as in figure 2 are still marked by capitals, but all variable dimensions are marked by lower case letters.

In studying the matter of correction we need only consider half of the image, as, if that half is corrected, the other must also be corrected as a natural consequence. The upper half only of the image is considered in working out the necessary formulæ, in which we employ the following symbols in addition to those used in equations 1 to 5.

$B$  = angle of inclination of negative from vertical;  $=QGz$  in figure 4,  $Gz$  being drawn vertical to lens axis.

$C$  = angle of inclination of copy;  $=peo$ .

$V$  = distance of correcting lens from negative;  $=lQ$ .

$U$  = distance of lens from copy;  $=pl$ .

$F$  = focal length of lens used for correction.

$x = V - F$ .

$R$  = ratio of copy to negative;  $= \frac{U}{V} = \frac{F}{x}$ .

**To Secure Correct Focus.**—The condition governing the attainment of correct focus must be considered first. In figure 4,  $Gn$  parallel to  $IQ$  and  $pe$  and  $eo$  and  $Im$  vertical to the lens axis. If the copy  $dpe$  is in sharp focus at all points then the distances  $pl$  and  $IQ$ , and also  $ol$  and  $lz$ , are conjugates, and

$$\frac{1}{U} + \frac{1}{V} = \frac{1}{ol} + \frac{1}{lz}$$

From the figure it is evident that  $U:V::ol:lm$ ; and  $lm:lz::lQ:ln$ , from these data we can arrive at the following equation.

$$\frac{U}{V} + \frac{\tan C}{\tan B} = \frac{F}{x} = R \dots \dots \dots$$

This equation must therefore be fulfilled when the copy is in sharp focus.

**To Secure Correct Width.**—In figure 2 draw  $GN$  parallel to  $IQ$ .

In figure 2,  $\frac{W}{w} = \frac{\text{width at } G}{\text{width at } I} = \frac{LN}{LQ} = 1 + \frac{H}{V} \tan A$ .

In figure 4,  $\frac{W}{w} = \frac{\text{width at } G}{\text{width at } I} = \frac{ln}{lQ} = 1 + \frac{H}{V} \cos B (\tan B + \tan C)$ .

Therefore as  $\frac{W}{w}$  in figure 4 equals  $\frac{W}{w}$  in figure 2

$$\cos B (\tan B + \tan C) = \frac{V}{F} \tan A \dots \dots \dots$$

This equation represents a condition that must be fulfilled when horizontal correction is secured. It allows  $B$  and  $C$  to vary, but we assign any particular value to one angle the other can then be found.

The following special cases should be noted.

If  $C=0$ , horizontal correction can be secured by inclining the negative only, so that

$$\sin B = \frac{V}{F} \tan A \dots \dots \dots$$

If  $B=0$ , horizontal correction is secured by inclining the copy only, so that

$$\tan C = \frac{V}{F} \tan A \dots \dots \dots$$

All these adjustments can be easily made tentatively without aid of formulæ, but the equations are of importance for purposes, as will be seen later.

**To Secure Correct Width and Focus.**—From equations 6 and 7 we can find that when the width is corrected and focus secured

$$\sin B = \frac{x}{F} \tan A \dots \dots \dots$$

$$\tan C = \frac{F \tan A}{V \cos B} \text{ or } \frac{F}{x} \tan B \dots \dots \dots$$

$F$  being the focal length of the correcting lens, the value depends on the scale of copying.

If B is found from equation 10, C can be easily arrived at by tilting the copy until the horizontal distortion disappears.

*To Secure Correct Height and Width.*—It is unnecessary to consider the correction of height alone, and the simpler equations that govern the simultaneous correction of height and width are easily derived.

Referring to equations 1 and 2, and to figure 2, if we divide the first equation by the second and transpose slightly we have

$$\frac{Hw}{Wh} = \cos A.$$

From figure 4 it is apparent that  $\frac{\cos C}{\cos B} = \frac{\text{Im}}{\text{IQ}} \times \frac{\text{GQ}}{\text{Gz}} = \frac{Hw}{Wh}$

Assuming that in figure 4 the copy is correct, w and h have the same value as in figure 2, therefore

$$\frac{\cos C}{\cos B} = \cos A. \quad (12)$$

This equation does not give definite values to either C or B, it only expresses a general ratio that must be fulfilled when the horizontal and vertical distortions are both corrected. Fulfilment of the ratio is not, however, necessarily imply correction. By combining equations 7 and 12 we can arrive at formulæ giving definite values to the angles.

$$\sin B = \tan A \frac{V^2 - v^2}{2Vv} \quad (13)$$

$$\sin C = \sin A \frac{V^2 + v^2}{2Vv} \quad (14)$$

The value of V is fixed according to the focal length of the lens, and the scale on which the copy is made.

Especially note, that from these formulæ C must always be greater than either B or A; and, V must be greater than v to secure opposite inclinations of the negative and copy, the condition necessary to obtain sharp focus.

If V=v, the angle B disappears and C becomes equal to A, which means that the conditions under which the original negative was taken must be restored more or less completely to obtain focus. If V is less than v, sin B is a negative quantity, which implies that the negative and the copy must both be inclined in the same direction; a condition quite antagonistic to sharp focus.

*To Secure Correct Width, Height, and Sharp Focus.*—If we multiply equation 12 by equation 6 we have a ratio expressing a condition that must be fulfilled when height, width, and focus are correct, viz.

$$\frac{\sin C}{\sin B} = \frac{U}{V} \cos A.$$

Dividing equation 14 by equation 13 we have a ratio that must be complied with when height and width only are correct, viz.;

$$\frac{\sin C}{\sin B} = \cos A \frac{V^2 + v^2}{V^2 - v^2}.$$

Therefore it is evident that to correct height, and width, and preserve sharp focus we must observe the following ratio

$$\frac{V^2 + v^2}{V^2 - v^2} = \frac{U}{V} - \frac{F}{x} = R. \quad (15)$$

That is to say, we must copy on a scale equal to  $\frac{V^2 + v^2}{V^2 - v^2}$ , which necessarily involves enlargement.

V being unknown until the value of R is fixed, equation 15 must be modified into a practicable form. From it we can find the value of x in terms of the known quantities F and v, thus

$$x = \sqrt{F^2 - v^2}. \quad (16)$$

It is then evident that

$$R = \frac{F}{x} = \frac{F}{\sqrt{F^2 - v^2}}. \quad (17)$$

Therefore, having a lens of known focal length, F, we can find the value that must be assigned to x to give an enlargement on the required scale, and, having set the copy and the negative at the proper distances from the lens, the angles can then be adjusted by

equations 13 and 14, but more conveniently by the simpler equations which follow.

From equation 15 we have,  $F = \frac{V^2 + v^2}{2V}$  and  $x = \frac{V^2 - v^2}{2V}$

Substituting these values in equations 13 and 14 we have

$$\sin B = \tan A \frac{x}{v} \quad (18)$$

$$\sin C = \sin A \frac{F}{v} \quad (19)$$

C can be adjusted to B tentatively, but note: as equation 18 is the same as 10, it follows that if we set out the angle B by equation 18 and tentatively adjust C to B, but omit to observe the correct scale of enlargement, we simply secure horizontal correction and focus as with equations 10 and 11. The observance of the correct scale introduces vertical correction.

If we adjust the angles by 13 and 14, the observance of scale introduces sharp focus.

Adjustment by 18 and 19 without observance of scale leads to no good result.

It is important to observe that from equation 16, correct height, width, and focus can only be obtained with a lens the focal length of which is greater than v. The greater the focal length of the lens the less the required ratio of enlargement to produce a perfect copy.

If we rely on stopping down the lens to secure focus, we can depart slightly from the proper scale, and with a lens of sufficient focal length can produce a corrected copy on a scale of equal size by the aid of equations 13 and 14.

It may be noted here that though in all cases equations for both angles have been given, yet in practice it will generally be sufficient to calculate one angle only, and to tentatively adjust the other until horizontal distortion disappears. If accurate vertical correction is essential, it is however better to calculate both angles.

If the angles dealt with are small, we may eliminate the trigonometrical ratios and substitute the size of the angles in degrees, for, with small angles, sines and tangents vary very nearly with the angles. The errors thus introduced vary with the value of V. For example, if in the equations we substitute angle A for tan A, and A is not greater than 15 deg., while V does not exceed 2v, the error in B is negligible. If A is 10 deg., V may equal 3v; or if A is 5 deg. V may equal 5v. Under these conditions the resultant angles are slightly too small.

*Correction when All Factors are Not Known.*—In all the systems of correction hitherto given it is assumed that we know the original angle of tilt, or the angle A, the distance v, and the position of the axial centre, Q. The latter factor may be assumed to be always known, as the point is usually the centre of the plate, but either A or v may be unknown, and in such a case the unknown factor may be determined as follows. Set the lens at a certain distance V from the negative, and focus the distorted image on a screen. Then incline the negative until convergency is corrected, and measure the inclination. The sine of this angle is equal to  $\frac{V}{v} \tan A$  (see equation 8) and from this value either v or A can be calculated, one of them being known.

If we know v it is not necessary to calculate A. Knowing v and having a lens of focal length greater than v we can find x (and therefore V and U) from equation 16. Set up the negative and the copy at the required distances from the lens, and find value of  $\frac{V}{v} \tan A$  by inclining the negative only. We can then adjust the negative and the copy, to secure correct height, width and focus, by the following equations, in which Y is substituted for the value of  $\frac{V}{v} \tan A$ , while R is the ratio of enlargement.

$$\sin B = \frac{x}{v} Y = \frac{Y}{R + 1} \quad (20)$$

$$\tan C = R \tan B. \quad (21)$$

If we ignore equation 16 and select another value for x we secure horizontal correction and focus only. Or we may secure horizontal and vertical correction only, by assigning a certain value to V, finding the corresponding value of Y, and then adjusting angle B by

$$\sin B = Y \frac{V^2 - v^2}{2V^2} \quad (22)$$

C can then be found by tentative adjustment, or by equation 21.

We know neither  $v$  nor  $A$ , we cannot find a true value for  $R$  and must assume one. We can then adjust the angle  $B$  by equation 20 and secure correct width and focus, but without knowing  $v$  we cannot secure correct height.

The value  $v$  can generally be pretty nearly ascertained if we know the focal length of the lens with which the original was taken. Assuming the original to be taken with a "fixed focus" camera,  $v$  has always a constant value, hence, if we always correct with a lens of certain focal length we must always enlarge on the same scale. This gives  $R$  a constant value, and also the other expressions which

occur in the formulæ,  $\frac{x}{v}$ ,  $\frac{F}{v}$ ,  $R+1$ , etc., etc.; the adjustments for correction are then very simple, whether we know  $A$  or not.

With hand-camera work  $A$  is not likely to be known, and we must find the value of  $Y$  and divide it by the constant representing  $R+1$  to find the angle  $B$ . It is not necessary to make any record at the time of exposure with a fixed focus camera possessing no movements. The lens being fixed, the axial centre can be automatically recorded on every plate by small notches cut in the edges of the rebates of the dark slides; and with a fixed focus enlarging camera, with central swings at both ends, the negative can be at once placed in exact register with the principal axis of the lens. The only adjustments then required are those of the angles.

### Estimating Amount of Distortion.

Assume the object to be a vertical rectangle measuring 5.5 metres in height and 4.5 metres in width. The camera is placed with its back parallel horizontally to the object but inclined vertically, the tilt being 15 deg. from the vertical. The lens axis is directed to a point in the object 3 metres from the top and 2 metres from the left side, and the distance from lens to plate is 12 centimetres. The ratio of image to object is as 1:50 and the dimensions of the correct inverted image, shown in figure 5, should be 11 x 9 cms., the axial centre  $Q$  being 6 cms. from bottom, and 4 cms. from right side.

To find the value of  $W$  in the distorted image we must consider each quarter of the image separately, as  $Q$  is not symmetrically situated; but it is only necessary to consider the upper and lower halves of the image when finding the value of  $H$ .

In upper half of image  $h=5$ , and from equation 1

$$H = h \cos A \frac{v}{v - h \sin A} = \frac{5 \times \cos 15^\circ \times 12}{12 - 5 \sin 15^\circ} = 5.413 \text{ cms.}$$

In lower half of image  $h=6$ , and from equation 4

$$H = h \cos A \frac{v}{v + h \sin A} = \frac{6 \times \cos 15^\circ \times 12}{12 + 6 \sin 15^\circ} = 5.131 \text{ cms.}$$

In upper right hand quarter of image  $w=4$ , and  $h=5$ , and from equation 2

$$W = \frac{wv}{v - h \sin A} = \frac{4 \times 12}{12 - 5 \sin 15^\circ} = 4.483 \text{ cms.}$$

In upper left hand quarter of image  $w=5$ ; and  $h=5$ ; and from same equation

$$W = \frac{wv}{v - h \sin A} = \frac{5 \times 12}{12 - 5 \sin 15^\circ} = 5.602 \text{ cms.}$$

In lower right hand quarter  $w=4$ , and  $h=6$ ; and from equation 5

$$W = \frac{wv}{v + h \sin A} = \frac{4 \times 12}{12 + 6 \sin 15^\circ} = 3.541 \text{ cms.}$$

In lower left hand quarter  $w=5$ , and  $h=6$ ; and from same equation

$$W = \frac{wv}{v + h \sin A} = \frac{5 \times 12}{12 + 6 \sin 15^\circ} = 4.426 \text{ cms.}$$

In figure 5, the distorted image is correctly set out with figured dimensions, and the correct image is repeated in dotted lines for comparison.

### Correction of Distortion.

To simultaneously correct height and width and secure sharp focus, it is necessary to employ a lens the focal length of which is greater than  $v$ . In order that results may be compared we will assume, in all cases, that a 15 cms. lens is required for the correction of the image, the distortion of which has just been calculated.

It is understood that the lens axis must always intersect the centre and that the values,  $v=12$  cms., and  $A=15$  deg., are constant. *Width Only.*—Assume that we copy on a scale of equal size, t

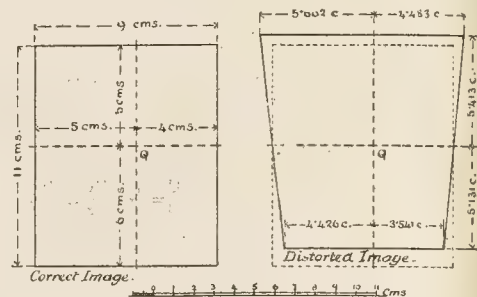

Fig. 5.

$V=30$  cms. If negative only is inclined, from equation 8 width corrected when

$$\sin B = \frac{V}{v} \tan A = \frac{30 \times \tan 15^\circ}{12} = .66985.$$

$$\text{or } B = 42^\circ .3'.$$

If copy only is inclined, from equation 9 width is corrected when

$$\tan C = \frac{V}{v} \tan A = \frac{30 \times \tan 15^\circ}{12} = .66985.$$

$$\text{or } C = 33^\circ .49'.$$

If both copy and negative are inclined, and we assume  $B=13$  deg., then from equation 7 we have

$$\tan C = \frac{V \tan A - v \sin B}{v \cos B} = \frac{30 \tan 15^\circ - 12 \sin 13^\circ}{12 \cos 13^\circ} = .446$$

$$\text{or } C = 24^\circ .32'.$$

The trigonometrical ratios must be observed with these equations. *Width and Focus.*—As before, assume we copy full-size,  $F=1$ , and  $x=F=15$  cms.

Inclination of negative is found from equation 10

$$\sin B = \frac{x}{v} \tan A = \frac{15 \tan 15^\circ}{12} = .33492.$$

$$\text{or } B = 19^\circ .34'.$$

Inclination of copy from equation 11

$$\tan C = R \tan B = \tan B$$

$$C = B = 19^\circ .34'.$$

Disregarding the trigonometrical ratios, we have the approximate results

$$B = \frac{x}{v} A = 1 \frac{1}{4} A = 18^\circ .45'.$$

$$C = RB = 18^\circ .45'.$$

This is a case in which  $V$  exceeds  $2v$ , while  $A=15$  deg.: therefore the errors in the approximate results are rather excessive. The error in each is less than one degree, the sum of the two exceeds  $1\frac{1}{2}$  deg.

*Width and Height.*—Still copying full size, we have,  $V=30$  cms. before, and

Inclination of negative is found from equation 13

$$\sin B = \frac{V^2 - v^2}{2Vv} \tan A = \frac{(30^2 - 12^2) \tan 15^\circ}{2 \times 30 \times 12} = .28133.$$

$$\text{or } B = 16^\circ .20'.$$

Inclination of copy from equation 14

$$\sin C = \frac{V^2 + v^2}{2Vv} \sin A = \frac{(30^2 + 12^2) \sin 15^\circ}{2 \times 30 \times 12} = .37528.$$

$$\text{or } C = 22^\circ .2'.$$

By approximate method

$$B = \frac{V^2 - v^2}{2Vv} A = \frac{(30^2 - 12^2) 15^\circ}{2 \times 30 \times 12} = 15^\circ .45'.$$

$$C = \frac{V^2 + v^2}{2Vv} A = \frac{(30^2 + 12^2)}{2 \times 30 \times 12} = 21^\circ .45'.$$

The combined errors are here less than one degree.

*Width, Height and Focus.*—In this case we cannot copy full size, and have to enlarge on a certain definite scale. We must therefore find the value of  $R$  before the angles can be calculated.

From equation 16

$$X = \sqrt{F^2 - v^2} = \sqrt{10^2 - 12^2} = 9 \text{ cms.}$$

$$R = \frac{F}{x} = \frac{15}{9} = 1 \frac{2}{3}.$$

$$\text{and } V = F + x = 15 + 9 = 24 \text{ cms.}$$

$$U = RV = 40 \text{ cms.}$$

Setting negative lens and copy at these distances, and knowing the value of  $A$ , we can find the inclination of negative from equation 18,

$$\sin B = \frac{x}{v} \tan A = \frac{9 \tan 15^\circ}{12} = .20095,$$

$$\text{or } B = 11^\circ 35'.$$

Inclination of copy from equation 19.

$$\sin C = \frac{F}{v} \sin A = \frac{15 \sin 15^\circ}{12} = .32352.$$

$$\text{or } C = 18^\circ 52'.$$

By approximate method.

$$B = \frac{x}{v} A = \frac{9 \times 15^\circ}{12} = 11^\circ 15'.$$

$$C = \frac{F}{v} A = \frac{15 \times 15^\circ}{12} = 18^\circ 45'.$$

As  $V$ , in this case, does not exceed  $2v$ , and  $A$  is not greater than  $45^\circ$ , the approximate results are very nearly correct.

If the angle  $A$  is unknown we can still find the values of  $x$ ,  $V$ , and  $U$ , as above; and then, after setting negative, lens, and copy at the proper distances, we can find tentatively the angle of inclination at must be given to the negative, alone, to secure horizontal correction. Assume that we find this angle to be  $32\frac{1}{2}^\circ$ , which is as far as we should be likely to get to the true value. Then, from equation 20, the required inclination of the negative can be found.

$$\sin B = \frac{Y}{R+1} = \frac{\sin 32\frac{1}{2}^\circ}{\frac{2}{1\frac{2}{3}} + 1} = .20056$$

$$\text{or } B = 11^\circ 34'.$$

Inclination of copy from equation 21

$$\tan C = R \tan B = .34110.$$

$$\text{or } C = 18^\circ 50'.$$

These angles are slightly less than those before calculated, owing to assumed slight error in measurement of angle which determines value of  $Y$ .

Fig. 6.

In figure 6 the methods of correction involving correct width and height, width and height, and width and focus, are illustrated. The position of the lens being fixed the various settings of negatives and copy can be compared. The arrangement securing correct width and focus is shown in dotted lines; that for correcting width and height in thin full lines; and that for securing width, height, and focus in thicker lines. The difference between the first two positions does not appear in the diagram to be very considerable, but the second position marginal portions of the image would be quite out of focus with a large aperture.

It should be noted here that the inclination necessary to secure focus must practically vary with the type of lens, when large apertures are used. The formulæ given are based on the assumption that the focal field of the lens is perfectly flat with near objects.

C. WELBORNE PIPER.

## A SOCIETY PROGRAMME.

As requested by a correspondent, we give below the programme of the Liverpool Amateur Photographic Association, referred to in our issue of last week:—

September 24: Lantern lecture, "Gorges of the River Ardèche," by G. E. Thompson.

The Ardèche rises in the mountains of the Cevennes. It is quite possible to travel through the Cevennes without a donkey! The lecture when completed will no doubt embody descriptions evolved by the lecturer after two visits to the district during last autumn and May of this year. At the time of going to press the slides were already finished; the libretto is simmering and awaiting inspiration. The following places are likely to be mentioned:—Aubenas, Vals, Thuyts, Jaujac, Antraigues, Largentière, Ruoms, Vallon and St. Martin. The crowning feature will be the more or less truthful accounts of two descents by boat through twenty-five miles of limestone gorges, amid crags and precipices stupendous, and shooting tempestuous and furious rapids surrounded by grand natural scenery unspoiled by the hand of man!

October 1: Lantern lecture, "The Life and Times of Shakespeare," by W. R. Yardley.

Synopsis: Shakespeare's historical and local environment—Parentage, Birth, and Schooldays—Marriage and Life in London—Theatres of the Period—His Work—Return to Stratford—Early Death—Monuments in the World—Portraits—Baconian Theory—Conclusion.

October 8: Lantern lecture, "Eastward Ho!" being reminiscent of a journey to Ceylon, India, and Burmah, by F. Gregory Jones.

Synopsis: Overland, through Mont Cenis to Brindisi—Suez Canal—Aden to Ceylon—Colombo Perydenia Gardens—Kandy and tea plantations—Southern India, including Dravidian Temples at Madura and Tanjore—Madras and Seringapatam—North-Western India, including Caves of Elephanta, Bombay—Kurrachee and Lahore—the Cities of the Ganges Valley, including Delhi—Agra—Lucknow—Cawnpore and Benares—at Darjeeling, in sight of the Himalayas—Mount Everest and Mount Kinchunga—Calcutta—Across the Bay of Bengal to Burma—The Great Pagodas at Rangoon and Mandalay.

October 15: Lantern lecture, "The Caucasian Alps," by Herman Woolley (President of the Alpine Club).

October 22: Beginners' demonstration, "Platinotype Printing," by C. F. Inston, F.R.P.S.

October 29: Monthly meeting. Lantern lecture, "By Battlement, Wall, and Tower," or Scenes in an Old Bavarian City, by James Shaw.

Synopsis: Limburg on the Lahn—Fine Romanesque Cathedral—A Noble Font—Regensburg—The Porch Beautiful—the long-drawn Aisle and fretted Vault—Bamberg—A Famous Crypt—Renovation as it should be—A Curious Monumental Tomb—Milteneburg on the Main—An Old World Market Square—Rothenburg o/d Tauber—A Unique Mediæval City—Walls, Towers, and Gates Galore—Picturesque Kindly People—A Glorious Market Place—The Three Town Halls—Quaint Interiors—The Fortified Church—The "Devil and the Rothenburger"—A Real Pageant—The Big Drink versus the Mighty Thirst—A Sudden Dive into the Middle Ages—Wonderful Representation by the Townsmen of the Siege and Capture of the City by Marshal Tilly during the Thirty Years' War. Characters splendidly realised—arms, armour, dresses, etc., carried out perfectly—Conclusion.

November 5: Practical demonstration, "Lantern Slide Making," by Fred. G. Tryhorn.

November 12: Lantern lecture, "Some Picturesque Midland and Cotswold Villages," by Wm. A. Clark.

Synopsis: The Avon Valley and Vale of Evesham contrasted and compared with the Cotswolds—The Heart and Soul of England—Shakespeare's Country—The Great Forest of Arden—The Dwellings of the People influenced by the Nature of the Country—Some Villages of the By-ways.

November 19: Practical demonstration, "Hints on Lenses for Photographers" (illustrated by lantern slides), by F. W. Parrott.

Synopsis: On Light; its propagation, reflection, and refraction—Formation of Images by Pinholes and by Lenses—Focus, Equivalent Focus, Conjugate Foci—Diaphragms: their value and use—Simple tests for common faults—Features of various types of lenses, Landscape, Portrait, Wide Angle, Rectilinear, Telephoto, etc.

November 22, Monday (Special): Lantern in use for members to test slides, from 8 to 9.30 p.m.

November 26: Monthly meeting. Lantern lecture, "Rambles and Scrambles on the Pacific Slope and in the Yellowstone Regions of the Far West," by Harold E. Young.

Synopsis: I Leave Japan—The Lonely Pacific—Honolulu—San Francisco in Earthquake Times—A Home on an Oil Field—Fruits at Fresno—The Yosemite Valley—Breaking the Trail to Glacier Point—Yosemite Falls—Prospecting Cloud's Nest—An Adventure with Bears—With the Red Indians—The Mariposa Grove of Big Trees—Back to San Francisco—Across to Salt Lake City—The Town of the Mormons—A New Trail in Wyoming—A Disaster on the North Fork of Snake River—Life on a Cattle Ranch—The Wonderful Yellowstone Regions—Geyser Land—Old Faithful—Among the Buffaloes—I Sight a Grizzly Bear—The Wild Animals of the Far West.

Entries for the annual competitions close November 30.

December 3: Practical demonstration, "The Printing, Developing, and Toning of Velox Paper," by W. F. Slater, F.R.P.S.

This demonstration will deal fully with the advantages of the various grades of this paper, and will be exceedingly instructive and interesting to all photographers using bromide papers.

December 10: Lantern lecture, "The City of Oxford," being a record of the society's Whitsuntide excursion, June 5 to June 9, 1908, by W. A. Taylor.

Synopsis: Views of the City and its College, as well as views taken in a drive through the Yorkshire villages of Botley, Cumnor, Northmoor, Stanton-Harcourt, and New Bridge. Included also will be views of Ashow, Kenilworth, and Warwick, visited by the party on the return journey.

December 17: Smoking social in club rooms.

December 24: No meeting.

December 31: No meeting.

1909.

January 7: Lantern Lecture, "The Sun's Corona," by Rev. Father A. L. Cortie, S.J., F.R.A.S., Stonyhurst Observatory.

January 14: The prize slides of the 1908 competition of the affiliated societies will be shown. In this competition the L.A.P.A. won second place.

January 28: Practical demonstration, "Carbon Printing," by Ernest Scott.

Synopsis: Preparing the tissue—Sensitising the tissue—Drying the tissue—Keeping the tissue—The Use of the Actinometer—The Actual Printing—Transfer to Single Final Support—Development—Double Transfer Process Explained—Temporary Support—Final Support.

February 4: Lantern Lecture, "Some Spanish Scenes and People, and a Bull Fight," by Arthur Marshall, A.R.I.B.A., F.R.P.S.

Synopsis: To Madrid—On the way there—Halting places by the way—Biarritz—Bayonne, Feuentarabia, civilisation in the slums—San Sebastian, the seaside resort, *par excellence*, its palaces and buildings—Climbing the Sierras—The Night Ride—Nightingales and Crickets—Burgos and its markets, and Madrid—The Bull Fight, types of Spanish beauty.

February 11: Lantern lecture, "Mountaineering in Skye," by Henry E. Bowron.

Synopsis: The Coolin—Sligachan—Sgurr nan Gilleann—Ridge Scrambling—Thirst—Climbing light—Camping out—Clach Glas—The Waterpipe Gully—Alleged wit—A First Ascent—How to Take Pictures—The Bhastair Face Traverse—Corrie Labain—The "Inaccessible" Pinnacle—Sgurr Alasdair—Amphibious Climbing—N.E. Ridge of Ben Nevis.

February 18: Lantern lecture, "May Certain Phases of Photography be Reckoned Among the Fine Arts?" by Lieut.-Colonel A. Grimshaw Haywood, V.D.

February 22, Monday (Special): Social evening and whist drive.

February 25: Monthly meeting. Lantern lecture, subject to be announced later, by Fred. W. Saxby.

March 4: Lantern lecture, "Painters as Story-Tellers," by Rimbault Dibdin.

Synopsis: The "Art for Art's Sake" Idea Considered—the Value of Subject in a Picture—The Teaching of the Past—Roman, Byzantine, early mediæval art—Religious Story-telling by Early Painters—Illustrated—The Birth of the Pictorial "Anecdote"—Illustrations of Stories, sacred and secular, and original inventions—The Services of Painters to Human Imagination in illustrating Bible story, history, and secular prose and poetry—The Seven Ages of Man, illustrated by notable pictures.

March 9, Tuesday (Special): Sale by auction of members' superfluous goods.

March 11: Practical demonstration, "The Oil Process" (by request) by Chas. F. Stuart.

March 18: Lantern lecture, "Spring Under Italian Skies," by Dudley Johnston.

Synopsis: Records of Sunny Days at the Italian Lakes and Verona—We Arrive at Lake Maggiore—Baveno and the Borromean Islands—The Lakes of Orta and Mergozzo—The Lake of Como—Menaggio—Varenna—The Tremizzina—Days on the Lake—Como—Milan—Verona—Venice, the Ancient Mistress of the Seas—the Beauty of Sunshine and Colour—Her Treasures of Art—The Pathos of December.

March 25: Monthly meeting. Lantern lecture, "Poetry and Photography of the English Lake District," by Dr. John W. Ellis, F.E.S.

April 1: Lantern lecture, "My Rambles with a Camera," by R. Davies.

April 8: No meeting.

April 15: Demonstration on "Stereoscopic Photography" (by lantern illustrations), by W. H. Tomkinson.

#### LECTURES AT THE L.C.C. SCHOOL OF PHOTO-ENGRAVING.

A SERIES of lectures has been arranged to be given by various specialists at the L.C.C. School of Photo-Engraving, Bolt Court, Fleet Street, on Wednesday or Thursday evenings from October 1908, to April 1, 1909, as shown below, at 8 p.m., upon subjects of interest to all engaged in any of the crafts concerned with illustration: in photography, and book, magazine, or newspaper production. Admission is free by ticket to be obtained upon application at the School.

ON PARTICULAR SUBJECTS, BY VARIOUS AUTHORITIES.

1908.

October 1.—A. Johnson: "The Selection of Photographs and Drawings for Illustrated Papers."

October 8.—G. H. Palmer, B.A.: "MS. Sources of Type Printed Decoration of Books."

October 15.—F. C. Tilney: "An Artist's View of Current Reduction."

October 22.—F. C. Batter: "Large Size Engravings and Illustrations for Publishers."

November 4 (Wednesday).—Will Rothenstein: A lecture.

November 11 (Wednesday).—W. H. St. John Hope: "The Art Treatment of Heraldry."

November 18 (Wednesday).—E. F. Strange: "Book Ornament."

November 25 (Wednesday).—W. Seymour: "Beauty and Simplicity in Art."

November 26.—A. J. Newton: "Some Considerations Affecting Photo-Mechanical Etching."

December 4.—W. Gamble: "Max Levy Etching Machine."

December 11.—Albert Etching Machine.

December 18.—G. Venner Dear: "Mark-Smith Etching Machine."

1909.

January 7.—Arthur Cox: "The Commercial Side of a Photo-engraving House."

January 14.—M. H. Calmels: "New Considerations on the Theory of the Cross Line Screen."

January 21.—C. E. Kenneth Mees, D.Sc.: "Some Applications of Theory to Practical Photography."

January 28.—R. Vincent: "The Process Man—A Character Study."

February 4.—A. G. Symmons: "Application of Photography to Lithography, including the Bitumen Grain Process."

February 11.—Colonel G. N. Grant: "The Production of Ordnance Survey Maps."  
 February 18.—A. J. Rowley: "Oils, Colours, and Varnishes in Relation to Lithographic Tin and Offset Printing."  
 February 25.—C. I. Smyth: "Colour Inks."  
 March 4.—J. R. Riddell: "Three-Colour Printing."  
 March 11.—J. Widdop: "Some Experiences of Lithography and Photo-Lithography."  
 March 18.—Arthur S. Newman: "The Design and Construction of Lithographic Cameras."  
 March 25.—A. Mackie: "Some Aspects of Technical Photography."  
 April 1.—H. W. Bennett: "Photography of Machinery."

## THE OPACITY OF BONES TO ROENTGEN RAYS AS AN INDICATION OF AGE.

(A Paper in the "Scientific American.")

ACCORDING to the law of Flourens, the duration of the period of life which bears a definite relation to longevity, and, in particular, the time occupied by any animal in attaining its maximum stature is a definite fraction, constant for all the individuals of the species, of the duration of the animal's life. Now, the maximum stature is attained simultaneously with the maximum development of the skeleton, and, as the weight of the skeleton is a function of the amount of mineral salts which it contains, the law may be expressed in a more mathematical form by saying that the percentage of mineral salts in the bones of all animals of the same species may be represented by similar curves of growth and decline, which will differ only in the values of individual constants.

Professor Charles Henry, taking advantage of the possibility of determining, indirectly, the mineral content of bones in the living subject, by means of their opacity to Röntgen rays, has been examining the hands of a large number of human subjects of various ages in order to verify the law of Flourens.

Henry used a Röntgen tube with a double anode, a Carpentier tube, and Lumière Sigma photographic plates. In order to eliminate the influence of variations in the tube and the coil, simultaneous radiographs were made of the hand and of a strip of aluminium foil of varying thickness, which served as a standard. After the plates had been developed the films were stripped from the glass, and the degree of transparency of certain parts was measured with a D'Arsonval diaphragm photometer. As the films are negatives, the transparency of the film is evidently proportional to the opacity of the bone. The portions of the film selected for photometric measurement were the image of the aluminium foil and usually that of the third phalanx of the middle finger. Finally, one of the films was taken as a standard, the aluminium strip of that film being compared in the photometer with the aluminium strip of each of the other films. The source of light for the photometer measurements was an Auer burner, the light of which was diffused by a ground glass screen. The opacities of the bones were expressed in thickness of aluminium.

From his examinations of subjects of various ages Professor Henry has deduced a maximum opacity at from 30 to 32 years (the age at which the height and weight normally reach their maxima), and a minimum opacity at 45 years. Tribob has supplemented these radiographic results by analysing the ash of bones of deceased persons of various ages and both sexes, with special reference to the percentage of calcium phosphate. The results of the chemical analysis confirm those of the radiographic examination, but appear to indicate a second minimum of opacity at 65 years of age.

The measurements that have already been completed are too few to warrant the drawing of more definite conclusions. A great many terminations will be required in order to establish the mean curve and find the positive or negative deviation corresponding to any given age. After all this has been done it will be possible to draw conclusions with respect to mean longevity and to calculate the "expectation of life" of a person of given age and measured opacity. It will then be possible also to calculate the personal coefficient of correction, and from this to establish life insurance premiums on a more equitable basis than is furnished by tables of mortality. But it would be a waste perhaps to ask insurance companies to change

a system which they have found so profitable or to endeavour to induce the insured to submit to an examination which would result in condemnation to death at a more or less distant date.

JACQUES BOYER.

## Photo-Mechanical Notes.

### Metal Printing Plates.

The production of a metal plate for half-tone and other processes, in which copper points are distributed throughout a zinc-plate, has been described in the recent specification (No. 9,500, 1908) of F. A. Roux, 12, Rue des Concours, Paris. The metal is obtained by first covering the zinc metal base with a layer of metal for printing (copper) and afterwards forming by mechanical pressure a large number of very small and fine holes which extend into both metals, the depth being the thickness of the superficial layer of copper.

The plate is next ground so as to form a smooth surface in which copper points appear in the midst of zinc points. In practice a sheet metal base (zinc, for example) is covered with a layer of copper, which is polished; then with an engraved matrix there is formed, by pressure, a chequer composed of small cavities very near together in this plate of coppered zinc. The surface of the plate thus matrixed is polished and then covered with small holes very close together in such a manner that the polishing produces a very smooth surface. The polishing reaches at least to the bottom of the small cavities, and the surface thus obtained shows points of copper which are those obtained in the plan of the bottoms of the small cavities, and points of zinc which are those of the subjacent metal uncovered by the wear due to the polishing of the copper which covers them.

These metal plates are very suitable for photo-engraving, heliographic engraving, and photo-lithography, either by directly applying a photographic image on the metal or by exposing the sensitized metal under a negative to obtain an etched plate.

In certain cases, after having applied a very thin layer of printing metal (copper) on the metal base (zinc), it is possible to transfer on to the surface of the metal which forms the covering a proof in fatty ink. Treatment with an acid which dissolves the metal in the part not protected by the fatty ink then follows, and, finally, the plate is cleaned to remove the protecting ink. A plate is thus obtained bearing the metallic image in slight relief; if required, a roller can be passed over the surface to level it.

### PHOTO-MECHANICAL PATENTS.

THE following patent has been applied for:—

STENCIL PLATES, No. 18,021. Improvements in stencil plates and in the process of reproducing drawings or maps by photo-lithography, photo-etching, zincography, or similar processes. Frederick Samuel Buckingham, 68, Primrose Mansions, Battersea Park, London.

### FORTHCOMING EXHIBITIONS.

September 11 to October 24.—Photographic Salon. Sec., Reginald Craigie, 5A, Pall Mall East, London, S.W.

September 17 to October 24.—Royal Photographic Society. Sec., J. McIntosh, 66, Russell Square, London, W.C.

October 13 to 17.—Southampton Camera Club. Entries close October 6. Exhibits by October 8. Hon. Sec., S. G. Kimber, Oakdene, Highfield, Southampton.

October 14 to 17.—Rotherham Photographic Society. Entries close October 5. Sec., H. C. Hemmingway, Tooker Road, Rotherham.

November 23 to 26.—Lancaster Photographic Society. Sec., J. Holt, 11, Fern Bank, Lancaster.

December, 1908, to January, 1909.—Kiew International Photographic. Sec., S. T. Horovitz, Technical Society, Kreshchtatik, 10, Kiew, Russia.

1909.

January 6 to 27.—Northern Photographic (Manchester). Entries close December 11, 1908. Sec., S. L. Coulthurst, Broad Oak Road, Worsley, Manchester.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between August 24 and 29:—

**LANTERN SLIDE BOX.**—No. 17,761. Improved box for holding lantern slides and the like. William Frederic Butcher, 322, High Holborn, London.

**CINEMATOGRAPH-PHONOGRAPH.**—No. 17,765. Improved means for effecting the synchronous running of gramophones and the like, and cinematographic apparatus. Alfred Wrench and William Engelke, 4, South Street, Finsbury, London.

**DEVELOPING APPARATUS.**—No. 17,907. Improved apparatus for developing photographic plates or films. Arthur Woolsey Blacklock, The Union Workhouse, Gateshead.

**DAYLIGHT DEVELOPMENT.**—No. 17,914. Daylight plate developing tank for use in connection with single dark slides straight from the camera without having recourse to the dark-room. Abram Zeitlin, 4, Northbank Terrace, North Kelvinside, Glasgow.

**CINEMATOGRAPHS.**—No. 17,920. Improvements in or connected with phonograph-cinematographic apparatus. Thomas Ernest Raymond Phillips, 15, Water Street, Liverpool.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**PRINTING FRAMES FOR COPYING SCREEN-PLATES.**—No. 10,802. 1908. The invention relates to a frame to be employed for the production of colour prints by successive staining in the different colours without moving the films. The frame is recessed to receive two plates, the original or negative and the printing plate, and on the main frame is secured by screws or otherwise a cover frame having a rubber cushion inside, which, when the cover is secured, presses firmly upon the film surface of the second plate, the latter carrying usually a bichromated film. The cover is deep and forms, with the plate and rubber cushion, a developing dish, allowing the plate to be treated while in place. At the other side of the printing frame is a removable light filter which allows parallel or conical light of the required colour to pass

and produce upon the second film the picture or pattern of the original. The second plate is printed by parallel or conical light of one colour, stained and developed, then recoated with emulsion, printed again by light of another colour and the process repeated for each colour employed, producing a true copy of the original.

The lower or main part A of the frame receives the light filter or coloured screen B at the lower side, secured by the buttons b or other simple means allowing it to be replaced. The frame A is recessed at a to receive the two plates C and D, C being the original and carrying a coloured film c on its upper surface, while the plate D has a bichromated or other film d, the two films being separated by the thickness of the glass.

The cover or second frame E rests on top of the flanged edges of the frame A and is secured firmly by means of the set screws e or other equivalent device. The lower side of the frame E is

channelled at e<sup>1</sup> to receive the india-rubber cushion F extending completely around the frame and pressing firmly upon the upper edge of the plate D. It will be seen that the frame E forms with the plate D and the india-rubber cushion F a developing dish of convenient depth and the film d can be treated in any desired manner without removing it from the frame or shifting its position in the slightest degree with relation to the plate C.

The method of using the frame for the reproduction of a colour picture or pattern, such (screen-plate) for example as a colour screen in which the colour elements form a mosaic, is as follows:—After the two plates C and D have been placed in position and the frame E secured on top, with a colour screen B, for example a red screen, at the bottom of the frame parallel light is passed through B and the coloured light resulting then passes through the screen or original film c reproducing exactly on the second film d the pattern of the original in the colour of the light employed. After suitable exposure in the manner the film d is stained appropriately and developed, leaving the red print. The plate D is recoated with emulsion and the plate B changed for a green screen and the process is repeated for the three colours or other number of colours employed in the original plate. The film d may then be transferred to paper if required.

Enlargements or reductions may also be produced by a slightly modified frame on employing lenses or reflectors to produce divergent or conical light, the printing frame being kept stationary throughout all the operations. The frame is in this case made so as to allow the original and copy plates to be separated at a substantial thickness of glass.

Reductions can be made from a large sized colour screen of a pattern, with the sensitive plate only in the recess, by focussing an image of the screen upon it. The frame is also useful for the production of colour blocks. A suitable method is to focus the plate through a mosaic colour screen and a different light filter for each block, develop and transfer to the block and bite the ground not protected; or the mosaic screen may be dispensed with and the three colours in the original picture copied successively.

As there is no relative movement of the films c and d the original picture or pattern can be reproduced with the greatest facility and accuracy, avoiding any special arrangement for registering. James Mark Child, 47, Harrington Street, Pearl Street, Derby.

**REFLEX CAMERAS.**—No. 10,469, 1908. The invention relates to reflex cameras of the type in which the reflector is pivoted at or near its centre between two rocking arms or levers which permit it to lie closely against the horizontal support and also against

inclined support, and is designed to provide mechanism for holding and releasing the mirror and other mechanism of the camera.

The camera body and the mirror A, the focussing screen B,

the hood C are of any ordinary construction. The reflector is pivoted between two levers D and D<sup>1</sup> between which it is free to swing loosely. The levers D D<sup>1</sup> are pivoted to the sides of the camera box by pins *d d*<sup>1</sup> and are connected by links *d*<sup>2</sup> with levers or cranks E on a rocking bar or operating rod F placed across the bottom of the camera box. The bar or rod F is provided at its end outside the box with an operating lever or handle *f* by which it is rotated in one direction.

The lever D is provided on its lower side with an arm or projecting member *d*<sup>3</sup> which when that end of the lever is drawn down engages and pushes back a latch G which holds it and retains the reflector A in its set or operative position until released. A similar latch G may be placed on the other side and the lever D<sup>1</sup> also provided with a projecting arm to engage therewith. The arm *d*<sup>3</sup> of the lever engages the shoulder *g* on the latch which prevents its return. The latch is provided with a projecting pin *g*<sup>1</sup> by which it is drawn back to release the lever D by a cranked rod H. The rod H extends to the front of the camera and is provided with a push knob *h* by which it is forced backwards to release the reflector being returned to normal position by springs *h*<sup>1</sup>. The rear end of the rod H is provided with an incline *h*<sup>2</sup>. Between the ordinary shutter releasing lever K and the side of the camera a swinging bracket L is placed with which the inclined end *h*<sup>2</sup> of the rod H engages when it is forced backwards and forcing the swinging bracket L outwards carries with it the lever K and releases the shutter. Thus the action of the rod is to first release the reflector A and then to release the shutter when set for a "time" exposure.

The reflector A is drawn back by the springs M attached to the connecting links *d*<sup>2</sup>, and the camera side.

The opposite or free ends of the levers D D<sup>1</sup> are connected to a hinged safety light excluder N by links *n* which raise the latter into close contact with the lower edge of the reflector A when drawn down.

A lever O is pivoted to the side of the camera box or body above the crank lever E the lower end of which the crank lever strikes when the latch G is released and the reflector A springs back. The upper end of the lever O is connected by a link *o* with a swinging plate P hinged to the side of the box or body above the lever O. A finger *k* on the shutter releasing lever K projects through the side and is engaged by the swinging plate P when the releasing lever is in the "instantaneous" position but is free of it when the releasing lever is in the "time" position. When the shutter is set for "instantaneous" exposure the movement of lever O and plate P releases the shutter independently of the inclined end *h*<sup>2</sup> of the rod H acting in advance of it. Thornton-Pickard Manufacturing Co., Ltd., Altrincham, Arthur Gray Pickard and Thomas William Piercy.

#### STEREOSCOPIC CINEMATOGRAPH PROJECTION.—No. 7,897, 1908.

According to this invention a special cinematographic film is used, the stereoscopic elements being formed in pairs side by side, that is to say, the small images are arranged on each side of a central line and the length of the film employed for each stereoscopic couple corresponds to two and a half perforations. Such a film is prepared as follows using standard film of 3.5 mm. width and standard perforation.

The registering apparatus is arranged so as to obtain a succession of stereoscopic images simultaneously on two films which each correspond to a lens, and the width of each image not exceeding one half of the width of the available part of each film so that, in two distinct operations, the whole of their surface may be utilised. This apparatus is composed of two lenses with a stereoscopic separation, of two vertical slides guiding the films and exteriorly eccentric in relation to the lenses: two openings limit the width of the images to one half of the distance between the interior edges of the two rows of perforations, that is to about 12 millimetres, and to a height corresponding to a width of two and a half perforations, that is to about 11 millimetres. The feed mechanism operating simultaneously on the two films is composed essentially of two toothed drums the mesh of which gear with the perforations; these drums are keyed on the same shaft to which appropriate mechanism imparts an intermittent rotary movement such that the feed of the films corresponds to two and a half perforations.

The printing apparatus will be arranged to be contact print

brook, photo- therefore possess a travel of five perforations and the opening of its window will correspond to the height of two images and to the width of one only. This window will be movable in the transverse direction to imprint the two sides in two successive passages. A registering point on the original positive film determines the departure of each impression with each negative film. In the first printing, the left hand row of images will be imprinted, for example, then the window will be displaced transversely for the second printing on the same positive film, the register of the first start being observed, so as to obtain a positive stereoscopic film on which the corresponding stereoscopic images are juxtaposed; the transposition is ensured seeing that the internal edges of the negative images at the moment of sighting become external on the positive film.

The stereoscopic film thus obtained is therefore composed of a succession of stereoscopic images capable of being confined in an opening measuring approximately 24 millimetres in width by 11 millimetres in height; in spite of the smallness of these images it suffices to present them to view as if they were the usual size of normal stereoscopic images, in which the width of each image

corresponds approximately to the mean distance between the eyes.

The arrangement forming the object of the present system realises these conditions, by the projection of small images on a translucent screen of the mean size of 7 centimetres by 14 centimetres, this screen being viewed in a stereoscope giving the same result as direct images of large size and the succession of images adding the illusion of motion to that of relief.

The drawing is a diagram of the vertical section of an automatic apparatus for animated stereoscopy objects of the invention. It consists of a cinematographic projector, a stereoscope with translucent screen, an endless stereoscopic film, travelling over a series of rollers, a motor actuating the mechanism, the whole enclosed in a case; a small electric lamp in the focus of a condenser illuminates the window of the projector and a single lens projects, juxtaposed on the screen, the enlargement of the stereoscopic pairs of film. Two unwinding drums, toothed, actuated by the motor, ensure the continuous feed of the film. The mechanical organs may be placed in operation by the introduction of a coin. The distance of the prisms or lenses of the stereoscope from the roughened glass constituting the screen is variable to permit of accommodation to the sight of the spectator. Charles Dupuis, 18, Rue de Paris, Vincennes, France.

**SCOPIC CINEMATOGRAPH PROJECTION.**—No. 2,584, 1908. The invention is an arrangement for the production of stereoscopic relief in a cinematograph projection. Two cinematographs are used for taking the pictures, which run synchronously and are arranged so that only every second section is exposed. Consequently, on the strip a picture alternates with a blank of equal size. The film bands made in this way are so printed that on a positive film the pictures belonging to each other, for the time being, of both cinematographs lie side by side. This object can be attained by two ordinary cinematographs being used in which an aperture of the shutter is closed, or the latter is so slowly turned round that the same only releases every second picture space. A positive film band produced in this way can be projected with any ordinary cinematograph.

As printing apparatus one of the cinematographs is here used of which the picture-taking apparatus consists. One and the same positive band is next printed under the one negative picture-strip and then under the other whereby the parts which have remained blank during the first printing are filled out by the second printing. After the development a positive band is received which consists alternately of single pictures of the right and left-hand lens of the stereoscopic-cinematograph. Dr. Boris Weinberg, University, St. Petersburg.

**CINEMATOGRAPH MECHANISM.**—No. 11,551, 1908. The invention is for mechanism for driving a band of film and includes a crank-disc and a transverse frame, a connecting rod between the crank-disc and the frame, a plate carrying claws and intermittently raised and lowered by the frame, claws for engaging the band and means for causing the claws to periodically engage with and move the band and disengage. There is also a reciprocating frame, a groove therein inclined centrally with straight ends and a slight projection at the junction of the inclined portion with one of the straight portions. Carlo Rossi, 85, Via Madama Cristina, Turin, Italy.

## New Trade Names.

**CEAZIT.**—No. 304,457. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives, but not including preparations for use in case hardening iron and steel, and not including any goods of a like kind to preparations for use in case hardening iron and steel. Alexander Waldberg, 9, Rue Benjamin Godard, Paris, France, Manufacturer. July 4 1908.

**CRAYONITE.**—No. 304,899. Photographic prints and photographic enlargements. Alexander Robert Hogg, 13, Trinity Street, Belfast, photographic specialist. July 22, 1908.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Notes on Bromoil.

There can be no doubt (writes Mr. T. H. Greenall, in "The Amateur Photographer and Photographic News" for September 8) that the gelatine of most bromide papers is rather too soft for the oil process when it comes to much brush work, and, of course, this is especially the case during the hot weather. The emulsion is apt to pull or rub up, and the use of any but the softest brushes is often attended with disastrous results. I have found, however, that treated, before making the silver print, with a solution of formalin in alcohol, these papers yield a surface which is everything the oil worker can possibly desire. Whether one uses the ammonia bath (which now does no hurt) or not, the papers so treated, whilst quick to take the pigment, allow any amount of after-work to be done on them, not excluding friction with an artist's flat hog-hair brush, and this after the paper has been in the moist condition for several hours. In fact, the worker has the same power of manipulating his work as in the oil process direct. The bath, which will keep and may be

used repeatedly, consists of 50 minims of 40 per cent. formalin, dissolved in five ounces of ordinary mineralised (methylated) spirit. The time of immersion is half a minute, and the paper is then pinned up to dry. Of course, several sheets may be hardened at one operation, but whether it is desirable to prepare more than is likely to be used during the next week or so I am not in a position to say. It appears necessary to use the formalin *before* making the bromide print, and not at later stages, when it has not proved successful in my hands.

## New Books.

"A Study of Splashes." By A. M. Worthington, C.B., M.A. F.R.S. (London: Longmans, Green, and Co.) 6s. 6d. net.

This is a well-printed and finely illustrated record of a remarkable photographic achievement. Mr. Worthington, with the assistance of Mr. R. S. Cole, Dr. E. B. Bryan, and Mr. G. F. Page, has for long time been engaged in the investigation of splashes, his method being that of photographing the splashes at intervals differing by about two-thousandths of a second, with exposures of less than three-millionths of a second. Naturally, no attempt was made by cinematographic methods. A drop or ball was allowed to fall into a basin of liquid and photographed at a certain interval of time after it commenced to fall. A second precisely similar drop was then caused to fall in exactly the same manner, and this was photographed on another plate after an interval one-thousandth of a second longer than the previous one. In this way a whole series of photographs was produced, giving practically the life history of the drop and its splash. The photographs illustrate the phenomena that occur both above and under the surface of the water, and the investigation covers the behaviour of liquid drops falling into different fluids, and that of polished and roughened spheres falling from various heights and at differing velocities into sundry media. From the physical point of view the work is most admirable, and though the subject may seem a trivial one to the uninitiated, yet the importance of the results obtained will be manifest to the reader.

Possibly the photographer will take the greatest interest in the manner of obtaining the records, and those unacquainted with the methods of practised scientific workers will perhaps be astonished at the comparatively simple arrangements that sufficed to produce the required results. Many valuable hints can be gathered from the chapter describing the apparatus. The catapult method of releasing the falling ball and the device for making the exposure at a predetermined time are both suggestive of ways of arranging shutter-testing apparatus. In regard to the photographic work, the results are beyond cavil, but still, considering that exceptionally sensitive plates were required, it seems curious that those mostly used were Thomas's A 1 ordinary, the Watkins number for which is only 13. Much faster plates were available. Then, again, we rather regret the fact that none of the results published are stereoscopic, as it appears to us that in work of this description the stereoscopic camera should be invaluable. Its use would not have added to the labour in any way, and the results might have given rather clearer records of some of the more doubtful details. The work done is, however, so admirable that we have no wish to criticise it, and we merely express a hope that the stereoscopic camera will not be quite ignored in further work done on the same lines. We refer on another page more fully to some of Mr. Worthington's expedients.

**OUTINGS FROM PLYMOUTH.**—Visitors to Plymouth and the West Country, more particularly those who carry a camera, will find the wants in reference to excursions, etc., anticipated for them and a quantity of useful information set forth in small space by Mr. Charles R. Rowe in a booklet bearing the above title. Mr. Rowe, in addition to being a photographer, has lived in the West Country for many years, and is, therefore, well able to advise those visiting the neighbourhood as to the best photographic localities and the best means of reaching them. Supplementary to brief topographical details, the cost of cheap day tickets by rail and steamer, with times of departure for both the outward and return journeys, are attached to each paragraph, thus relieving the visitor from the

ssity of consulting time-tables, etc. The little book is well  
trated, and may be obtained for the small sum of 3d. from the  
s of the "Western Morning News" Company, Limited, 31,  
rge Street, Plymouth.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### SATURDAY, SEPTEMBER 12.

deen Photo Art Club. Excursion to Parkhill.  
a Camera Club. Excursion to Bolton Woods  
and Stereoscopic Society. Outing to Wimbledon Common.  
pool Amateur Photographic Association. Excursion to Mount Wood,  
Moreton.  
a Suburban Photographic Society. Excursion to West Wickham; A. E.  
Bache.

#### TUESDAY, SEPTEMBER 15.

chester Amateur Photographic Society. "Amongst the Lakes and Fells of  
Lumberland with a Camera." J. Hayward.

#### WEDNESDAY, SEPTEMBER 16.

y Photographic Society. Excursion to North and South Kilworth. G. B.  
Morgan.  
h Middlesex Photographic Society. Lantern Slides. G. E. Williams.  
a Suburban Photographic Society. Portfolio and Print Competition.

#### THURSDAY, SEPTEMBER 17.

on and Provincial Photographic Association. Business Meeting.  
end-on-Sea Photographic Society. *Photographic News and Photography*  
Prize Slides.  
sworth Photographic Society. Exhibition of Home-Made Apparatus;  
T. W. Goulding, K. G. Collins, and A. E. Cope.

LEEDS PHOTOGRAPHIC SOCIETY.—The members of this Society had  
most enjoyable excursion to Knaresborough on Saturday last, the  
inst. Although the weather was dull, there was a large muster  
members and friends. The party were met at the station by the  
Canon Hancock, M.A., Vicar of Knaresborough (an old member  
the Society), and under his guidance a most delightful afternoon  
spent. Through the kindness of Canon Hancock, permission to  
ograph had been obtained from the various owners of property in  
district.

The new lecture hall of the Leeds Photographic Society is at the  
Institute, Cookridge Street, and members of the Institute are  
admitted to membership at 5s. per annum, ladies 2s. 6d. The meet-  
ings are held on the Tuesday evening throughout the session, the  
Institute lectures being held on the Wednesday evening. The winter  
programme of the Society is now completed, and intending members  
will apply for a copy to the Hon. Secretary, Mr. R. MacKay, 69,  
on Street, Leeds.

## Commercial & Legal Intelligence.

DISSOLUTION OF PARTNERSHIP.—The partnership between Messrs.  
er Edward Jeffery, Campbell James Beckwith Edwards, and  
us Morison McLeod, carrying on business as photographic artists  
5 and 56, Mattock Lane, Ealing, under the style of "Jeffery,  
ards, and McLeod," has, by mutual consent, been dissolved as  
June 1. All debts due to, and owing by, the firm will be  
ived and paid by Messrs. Jeffery and McLeod.

BEXLEY HEATH BANKRUPTCY.—George Robinson Harris, trading  
s. R. Harris and Co., at 22, The Broadway, Bexley Heath, as a  
ographer, picture-frame maker, and wholesale stationer, has  
been adjudicated a bankrupt, and his public examination took place  
the County Court, Rochester, on Monday, September 7.

#### NEW COMPANIES.

MUENZER, LIMITED.—Capital £25,000, in £1 shares (12,500 prefer-  
). To take over (1) the business of a manufacturer of, and dealer  
all kinds of, photographic reproductions, photographic apparatus  
chemicals, picture frames, etc., carried on by M. Muenzer, at the

"Helios" photographic works, 336-340, Chester Road, Cornbrook,  
Manchester; and (2) the business of a photographic artist, photo-  
grapher, dealer in photographs, etc., carried on by the said vender  
at 71-5, Grosvenor Road, Manchester, and elsewhere, as the "Great  
Britain Fine Art Company." No initial public issue. The number  
of directors is not to be less than three nor more than seven. Max  
Muenzer is one of the first. Qualification (except Max Muenzer), £250.  
Remuneration as fixed by the company. Registered office, 336-340,  
Chester Road, Cornbrook, Manchester.

NOBLE'S DRUG STORES, LTD.—Registered August 27. Capital  
£1,000, in £1 shares. Objects: To adopt an agreement with W. D.  
Noble, and to carry on the business of chemists, druggists, dealers in  
photographic requisites, etc., as formerly carried on by him at 2,  
Wells Street, Cable Street, E., as Noble's Drug Stores. Private  
company. Registered office, 2, Wells Street, Cable Street, E.

## News and Notes.

BLACKBURN AND DISTRICT CAMERA CLUB.—The hon. sec., Mr.  
Arthur Clayton, advises us of the change in his address, which is  
now Wycollar Road, Revidge, Blackburn.

BOLT COURT CLASSES IN PROCESS.—The winter session of the Bolt  
Court School of photo-engraving and lithography will open on  
September 21, and intending students may now obtain the prospec-  
tus and time table by applying to the Principal, at 6, Bolt  
Court, Fleet Street, E.C. The popularity and excellence of these  
classes is attested by the numbers who attend them and the  
results achieved, and the small fees required bring them within  
the reach of all who are employed in or qualifying for trades or  
occupations upon which the instruction given at the school has  
a distinct bearing. The following is a list of certain of the  
evening classes for students in process work.

Section I.—*Photography for Reproduction Processes*.—The pre-  
paration of originals for reproduction; teacher, F. W. Brookman.  
Mondays or Fridays, 7 to 9.30 p.m.

Line and continuous tone negative making (beginners); teachers,  
A. J. Bull and W. J. Smith. Tuesdays, 6 to 8, or 8 to 10 p.m.

Advanced line and continuous tone negative making; teachers,  
the Principal and W. J. Smith. Wednesdays, 7 to 9.30 p.m.

Technical photography for catalogue illustrations.

Screen negative making; teachers, the Principal and A. J. Bull.  
Mondays, 7 to 9.30 p.m.

Tri-colour block making; teacher, the Principal, assisted by  
A. J. Bull and A. Anning. Thursday or Friday, 7 to 9.30 p.m.

Section II.—*Processes for Relief Printing*.—Line blocks on zinc,  
brass, and copper. Mondays or Fridays, 7 to 9.30 p.m.

Tone blocks on zinc, brass and copper. Tuesdays or Thursdays,  
7 to 9.30 p.m.

Fine etching. Wednesdays or Thursdays, 7 to 9.30 p.m.

Mounting process blocks. Mondays and Fridays, 7 to 9.30 p.m.

SCIENTIFIC PHOTOGRAPHY.—The Calendar of the Imperial College  
of Science and Technology for the session 1908-9, just issued, contains  
particulars of the instruction in scientific photography given in the  
chemistry department by Mr. Chapman Jones. A course of four  
lectures will be given during the first term. These lectures will  
be repeated if necessary in the second term. The syllabus includes:  
The aims of photography and a consideration of the elements of truth  
in pictorial representation; the functions of the camera or its equiva-  
lent; the production of images; the practical use of lenses; their  
focal lengths and apertures; the aberrations of lenses, especially  
chromatic aberration; their correction and their effects on photo-  
graphy; the principles of the operations concerned in the production  
of negatives and prints; the relationship between the original object,  
the negative, and the print.

A course of about twelve lessons in practical work will be given  
during the second term. This will include: The measurement of  
the focal lengths and apertures of lenses; the production of nega-  
tive from solid objects, diagrams, engravings, line drawings, book

illustrations, etc.; experiments on the effects of colour in photography; the preparation of lantern slides, silver prints by development, platinum prints, and carbon prints.

MR. C. A. G. BROWNE, having sold his interest in the lease of Nos. 53 and 54, Wych Street, to the London County Council, he has removed his advertising offices to No. 20, Wellington Street, Strand, W.C.

At the British Association Congress, Professor Wager, according to the "Manchester Daily Guardian," credited plants with certain photographic functions. His theory is, that by means of a peculiar property of their outer layers some leaves act as lenses. "Convex formations," the Professor said, occurred practically in all leaves, but were most strongly marked in plants grown in the shade. He suggested that their function might be to promote a more effective distribution of the light, upon the absorption of which by the chlorophyll, or green substance of the plant, depends the food supply of the plant; or they might bring about the stimulus by which the plant moves its leaves so as to receive the maximum amount of light. By means of the lenses the plant could perhaps to some extent perceive the difference between light and darkness, and the movements of the plant might be modified accordingly. Moreover, as excess of light tends to destroy the plasma chlorophyll, it is of great importance that such should be evenly distributed from a point within the cell instead of acting injuriously by excess at the surface and failing to reach the deeper layers." It is further stated that remarkably clear photographs were shown upon the screen taken through the lenses of leaves—photographs (reproductions must have been meant) of Huxley and Darwin, of the author's niece, of landscapes, and so on. Plants that grow in the shade appear to be mostly gifted with these wonderful capacities.

## Correspondence.

\*\* We do not undertake responsibility for the opinions expressed by our correspondents.

\*\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

### THE HYPO BAG.

To the Editors.

Gentlemen,—Noticing your paragraph, "Frilling," in your "Answers to Correspondents" of September 4, we think it possible your correspondent is using hypo solution too strong. Some years since we had a complaint from an operator that some plates would not fix, and found this to be the reason.—Yours faithfully,

Southgate,

September 7, 1908.

WELLS AND CO.

### SOCIETY PROGRAMMES.

To the Editors.

Gentlemen,—Noticing your paragraph in to-day's "British Journal of Photography" re "Society Arrangements," as our secretary is from home, I send you the above society's prospectus for the coming session, and will be glad if you will include our fixtures in your "Societies" column. Your remarks re the Liverpool Amateur Photographic Association's fixture-list has made me curious to see it, and I think there would be many others like myself in this way. Do you not think it would prove of interest to a great many of your readers if you would publish one or two of the best fixture lists sent? I am sure it would give some societies a few hints which would be useful at this time.—I am, yours truly,

Edinburgh Photographic Society,

13, South St. David Street, Edinburgh.

J. F. DUTHIE.

[We hasten to do our Edinburgh friends the justice of saying that their season's programme reaches us with a full list of fixtures up to June, 1909. We reprint the Liverpool programme in another column.—E.N.S. "B.J."]

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO. 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street Strand, W.C. undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

- J. Yeoman, Bedale, Yorkshire. Photograph of the Bedale Cricket Club.
- A. R. Siddals, Wood Lane, Newhall, Burton-on-Trent. Photograph of a View of Burton-on-Trent on a Cask.
- The Rev. J. Ward, St. Mary's, Lanark. Photograph of Proposed Church of St. Mary's, Lanark, with Plan. (From a Drawing.)
- G. C. Smith, The Studio, Giffnock, near Glasgow. Photograph of Geo. Gray, Junr., King's Prisoner.
- C. E. Willis, 92, Newport Street, Bolton. Photograph of the Bury Football Club, Season 1908-1909, with Names.
- H. R. Edmonds, Trading as Whitfield Cosser & Co., 3, High Street, Devizes. Photograph of the Picture Gallery and Photograph of the Drawing-room of Devizes Castle.

CHANGING-BAG.—Would you kindly tell me through "B.J." the cheapest way to make a 1-plate changing bag, what material should have to get, and about the price I should have to pay?—OLD READER.

When you can get a changing bag of excellent make and pattern, such as Beresford's, for 7s. 6d., it is hardly worth your while to make. "Ruby Christia" (from any large photographic dealer) used with one or two thicknesses of best thin silesia lining are suitable materials.

BUILDING CAMERA.—Will you kindly inform me where I can obtain a copy of a book on stand camera (1-plate) building, one about 6d. or 1s.?—G. W. B.

We know of no such book. At the present price of half-plate camera sets, we cannot believe there is any demand for such a publication.

TIME DEVELOPER.—Please quote in your next issue a formula for a pyro-soda non-staining time or stand developer for portraiture to use at 65 deg. F., development to be complete in 6 minutes suitable for the development of contrasty subjects, such as camp photos where the subjects have sunburnt faces taken against white tents?—PYRO.

The pyro-soda developer advised by Messrs. Wratten and Wainwright for their plates just about answers to the conditions named in your query.

LENS QUERIES.—1. I shall be greatly obliged if you will inform me on the following points. If a lens at  $f/8$  gives a correct exposure in 1 sec., what exposures would be right for same lens at  $f/4.5$  and  $f/6.2$  respectively? 2. If a  $9\frac{1}{2}$  in. lens at its natural focal distance gives a correct exposure at, say, 1 sec., what exposures will be necessary for same lens and aperture at, say 8 ft. and 10 ft. respectively from the object?—H. KENNETH.

The exposure is proportional to the square of the aperture number, that is, if  $f/8$  requires 64 secs.,  $f/4.5$  requires 11.25 secs. and  $f/6.2$ , 38.44 secs. Dividing these times by 64 we get .18 secs. for  $f/4.5$  and .6 sec. for  $f/6.2$ . 2. In the case of the object 8 ft. distant the exposure compared with that at normal extension is  $1\frac{1}{4}$ ; in the case of the object 10 ft. distant, the ratio is almost exactly  $1\frac{1}{2}$ .

SULPHIDE TONING.—I am enclosing two prints, which I have tried to tone by the sulphide method. I have done a good many before but have never had this trouble before. The prints were made on Barnet extra rapid bromide paper, developed with Mequin, then fixed for fifteen minutes, and well washed and dried. I used the toning formula given on page 325 of the "B.J.A." After bleaching

shed them from ten to fifteen minutes, and then alumed for three minutes, rinsed, and toned. I might say the black white prints were excellent beforehand. Also, can you tell me how to prevent blisters on prints during toning?—PRINTER.

The only suggestion we can make is that your sulphide solution is stale. Hypo has evidently been at work on at least one print has nearly destroyed the image. Sulphide solution that has deteriorated always contains hypo. Blisters in sulphide toning are always formed if the prints are left in the sulphide too long, than five minutes is always risky. The best precaution is to immerse the prints with a formalin bath before toning. Also be sure all solutions are of about the same temperature. When the prints come out of the sulphide bath they should be soaked in water for a few minutes before washing. If put immediately under a stream from the tap blisters are almost certain to appear.

CAMERAS.—I am much struck with the remarks made *re* small cameras in this week's "Analecta," as it strikes me that it is just what I want. Can you give me the name of the firm that supplies cameras referred to, or the name of a similar camera, and where I can get it? I think that if the lens was a modern anastigmat it would be a plate about 1½ inches square, say, quite crisply, and with a depth of focus at, say,  $f/4$ , which would be very convenient. Don't you think that the grain of the plate would make the prints look rotten if enlarged to 15 x 12?—OTHELLO.

Messrs. Jules Richard, 23A, Albemarle Street, London, W., supply the best camera of this class. There are plenty of plates which will enlarge satisfactorily to the dimension named, but the price must be thin and full of detail.

T.—If the goods sent were not according to pattern you would have returned them at once and not have used them. With reference to the broken frame, you must bear in mind that most of those who enlarge for the trade announce on their circulars that they are not responsible for damages in transit. With regard to the enlargements, we can express no opinion whatever, we have not seen them, or the originals from which they were made. You must keep in mind, however, that you must not expect first-class and artistic work for a small price. If the case reaches County Court the judge will have to decide if the work is fair for the price paid for it. He will also have to decide who should bear the cost of the warehousing at the railway station. If you refer the matter to the Professional Photographers' Association they will probably get the matter settled for you quickly, and to your satisfaction—that is, supposing you are a member of that association.

ENLARGING LENS.—When using enlarging lantern I find the objective becomes covered with condensed moisture and opaque as ground glass. Can you tell me the reason for this, and the remedy?—BEWILDERED.

The cause is evidently bad ventilation of the enlarging lantern. An arrangement for air to circulate in the lantern body and the part through the lens the trouble should cease.

ON PRINTS.—Would you be kind enough to let me know in the case of the cause of spots appearing on the prints when being developed. I toned about 300 prints in the same bath; 250 I developed on cards which were quite free from spots after going through the hot roller. The twenty that came from the enameller were covered in spots like the one enclosed.—SAM BRICK.

The spots are evidently due to particles of iron rust. Where they come from it is impossible for us to say definitely; but they appear to come from the enameller, as upon close examination we see that some of the larger ones have really indented the surface of the plate. Possibly some parts of the enameller had rust upon them when it was used.

RE.—For a special purpose I desire to convert the developed image on a lantern plate into a substance which shall appear pure white by transmitted light, and which shall remain unaffected by exposure by daylight. I have tried converting into ferrocyanide and iodine, but both show a distinct tinge of colour. I fancy the cyanide might do, but I cannot succeed in converting the image into cyanide. If you can in any way assist me to bring about the desired result, I shall esteem it a favour.—TRANSPARENCY.

We do not know of any silver compound that is white by transmitted light and insensitive. The whitest we know is silver iodide developed with ammonia. We should think that the only way of pro-

ducing a white image will be by either the carbon or dusting-on process.

A WATER-RATE QUERY.—I am writing to ask your advice on the following. I have always paid a water-rate of 5s. per half-year, until last December, when some meddling person made it their business to complain to the Water Committee that I used a large quantity of water for my business, and that I ought to have a water meter fixed. So the Council sent their men to fix one, and the water is charged at 6d. per 1,000 gallons. During the six months that the meter has been fixed I have used 17,000 gallons, thus making my water cost 8s. 4d. for the half-year instead of 5s., and then they are charging me rent on meter 3s. 6d. for the half-year, making it 11s. 10d. altogether. This is not what I mind so much, but that I cannot see it is fair that I am made to pay in this way, while there are two other professional photographers in the town who are not compelled to have a meter fixed. If I am to be made to pay, why not they as well? This I pointed out in a letter I wrote to the Water Committee soon after meter was fixed, and it was laid before their next meeting, but I never received any reply to it. I enclose you a copy of letter I sent to them. What I want to ask you is: Can the Council make me pay in this way if the other two do not? and what would you advise me to do in the matter?—UNFAIR.

All water companies and water boards have their own laws and by-laws, and one of them is, usually, that when the water is used for business purposes they can have a meter fixed so that the consumer pays for the actual quantity used. They can also charge a rent for the meter. The meter clearly shows that hitherto you had been using more water than you were really entitled to do. All you can do is to pay the account, and economise the water as much as you can in the future. That your neighbours have not been compelled to have a meter is really no concern of yours, and a matter in which, so far as we can see, you cannot directly ask for interference.

DISCOLOURED OIL-COLOURED PHOTOGRAPHS.—Enclosed two silver prints, painted thickly in oils, were taken to Ceylon. You see the condition they were in when opened. You will see on one I have removed some of the coating with a little turps. Both were in perfect condition when they left this country. I have known silver prints to fade a little, but never paint. If you could throw any light on this matter you will greatly oblige.—T. BRUCE.

The appearance of the pictures is certainly strange. Paint, even oil-colour, will not prevent a silver print from fading, and the fading, or staining, will show through the colour. Without knowing how the prints were toned, and the pigments actually used in the colouring, it is impossible to say the precise cause of the appearance. It would seem, however, that the final colour or glazing laid on the lights contained a lead compound which has darkened by exposure to some sulphurous emanations. Is it possible that the prints were "sepia," toned with sulphur? The photographs have been returned as requested.

H. C. L., J. A. C., E. A. RAYNER, AND OTHERS.—We will reply to your queries in our next issue.

ACID SULPHITE.—I was greatly interested in reading M. Balagny's article on the use of acid amidol as a developer for plates. Unfortunately, I have not been able to give it a trial owing to my inability to procure the soda bisulphite lye he mentions. Could you let me know through the medium of your paper: (1) Whether potass metabisulphite would be as suitable, and (2) what strength of solution would be equivalent to the bisulphite lye of 35 deg. Beaumé suggested. M. Balagny, I believe, mentions that a 5 per cent. solution would be about right, but as far as I can see 25 per cent. would be nearer the value. If I knew the strength of the bisulphite lye in regard to its percentage of pure salt ( $\text{NaHSO}_3$ ) I would, perhaps, be able to calculate the rest for myself.—GEO. L. STEVENS.

(1) We use potassium metabisulphite with perfect success, our formula being: Soda sulphite, 1 oz.; potassium metabisulphite, 1 drachm, and amidol or diamidophenol 40 grs. to every pint of the developer. This is not equivalent to M. Balagny's formula, but it works well with bromide paper. Sometimes we use bromide with it about ½ grain per ounce. (2) The commercial solution of bisulphite mentioned by M. Balagny can be obtained from the Lumière Co., 89, Great Russell Street, and your dealer can get it for you without any difficulty. We understand it to be

about a 50 per cent. or saturated solution, in which case it is impossible to make a metabisulphite solution of the same strength. The equivalence in development processes of sodium and potassium salts is so doubtful a matter that we prefer to use the actual solution recommended when testing the formula.

**ROYALTIES.**—Can you please give me the percentage usually asked for patent royalties, or direct me to the information.—H. F. T.

There is no regular scale; it is a matter of contract.

**NON-ACTINIC DYE.**—I want to stain gelatine films, so as to stop the passage of all actinic light. Could you recommend me a dye to use?—A. W. B.

Use a pair of films, one dyed with a mixture of tairazine and rose bengal; the other with methyl violet.

**P.O.P. STAINS.**—Will you kindly inform us what is the cause of stains appearing on backs of P.O.P. cards, as on the enclosed? You will note that on one the stain is appearing on the front as well as the back.—DIOCLE.

We cannot definitely suggest the cause of the stains without details of method of working. Possibly you are treating too many cards at one time, and so some do not get full benefit of the washing, etc.

**DUPLICATE NEGATIVES.**—Will you please let me know, through the "Journal," the best way to get good duplicates from negatives? I prefer a method of contact, with slow plates if possible. What would be the exposure at a given distance from a 16 c.p. electric lamp? What would be the best plate to use and what developer? Is it possible to produce really good duplicates?—DUPLICATE.

A very satisfactory method is that given on page 838 of the "Almanac," 1908.

**THIRTY YEARS' SUBSCRIBER.**—The A pattern has been most used, and has given the best results, partly, no doubt, because it has been longer on the market. Both are certainly good lamps, but B is not so convenient in use.

**PORTRAIT GAS LAMP.**—Could you tell me, through the medium of the "Journal," the makers of a gas lamp for portraiture with inverted mantles?—M. A. B.

The Tress Company, 4, Rathbone Place, Oxford Street, W.

**FIGURES IN GROUPS.**—Can you tell me the method of removing a figure from one negative and inserting in another, by means of hydrofluoric acid?—FLUORIC.

The negative with the figure to be introduced is first stripped from the glass. This may be done by the method given on page 498 of the volume for 1907, or by that given on page 391 of the current volume "for the repair of broken negatives." When the film is removed and washed it is dried between blotting-paper, which will keep it flat. When dry it is placed on the negative (laid on the retouching desk) in the position it is to occupy, and, with a sharp penknife, it, together with the film on the negative, are cut cleanly through to the glass. The film is then neatly scraped off the glass, and the film one, which will accurately fit the space, introduced and secured into position with a few touches of a clean solution of gum.

**AXAX.**—The four prints sent, focussed on different points of the newspaper, show that the lens has a very much rounder field than the generality of lenses of this type. You would be quite warranted in returning it to the dealer from whom you had it, for exchange.

**GROUP IN CONFINED SITUATION.**—We have the interior of a workshop to take, with the workmen at their benches and lathes. The workshop is fairly well lighted, but it is very long and narrow. The owners want all the figures good. The size of the picture is to be 12 x 10. Some of the men will be very close to the camera, as that cannot be placed very far back, while those at the far end of the shop will be 60ft. or 70ft. away. We have a R.R. lens (12 x 10), of 17in. focus, and a 10 x 8, which, when well stopped down, will cover the 12 x 10 plate. These are the only two lenses, except portrait ones, we have. Which would you advise us to use?—COMPY.

If you can get far enough back to include the whole of the subject required by all means employ the larger one. But in either case, in order to get the nearest and most distant figures in fairly good focus, a small stop must necessarily be used. The best way will be to focus with a middle size stop at nearly the centre of the

picture, and then stop down until the image is fairly sharp over.

**LENS QUERY.**—I have a large portrait lens offered to me and I think is a very low price. It is about 4½ in. in diameter and is said to take a 12 x 10 portrait. It bears the name of "Paris." I have not yet tried it, but I have misgivings, as the glasses has two or three small air bubbles in it, and slightly chipped at the edge. What I am in doubt about is Will the air bubbles and chip very materially interfere with quality? The price I am asked for the lens is four guineas.

The chip will practically in no way interfere with the view of the instrument, if it be covered with a touch of black varnish. As regards the air bubbles they are also of no consequence. Of the newest and most costly anastigmats have several air bubbles in them, but they are of no moment. Jamin had a good reputation as a maker of large lenses, and we should say that the value you have offered to you will be good value for the money.

**COPYRIGHT BLUFF.**—I have opened a business at the above address, and while the studio was building I filled up my time in the views of the neighbourhood for postcards, which I am now selling. Another photographer in the place, it now seems, has taken the same views, and made them copyright. He is now threatening me with a lawsuit, saying that he had already copied those views. Can he do so, as I took the views direct? He is "sore" at my starting business in the place, as he had had all the trade to himself. I know also he will do me no injury he can.—COUNTRYMAN.

Your neighbour can, of course, do nothing—but bluff making his views copyright he did not make the scene itself right. That is impossible. You have surely noticed the frequent instances of this sort of thing mentioned by our readers.

**J. C. AND CO.**—By all means adopt the dark blue fabric. It would prove very unsuitable as curtains for a photographic studio. It would be all right at first, but would not last long. The fabric would probably fade with the strong light in the course of a few months.

**R. C.**—It is quite outside our province to give directions for faded studio curtains, but we should not recommend you to do so to do the work yourself. Your best and cheapest way will be to send the curtains to a dyer. But we would advise you to satisfy yourself that they are worth dyeing, for in many instances when curtains have faded to the extent you say yours have, the fabric has become so rotten that it will not bear dyeing. The dyer will advise you upon this point.

**R. BORROWS.**—The reason the matt varnish, made according to formula in the "Almanac," is so coarse and granular is that too much benzole was added. The preparation of benzole depends on the coarseness or fineness of the grain. With a small proportion it is very fine, and with a large one it is coarse, as in the case sent. The only thing you can do is to make a fresh lot. At the same time we should advise you to add the benzole in small quantities at a time, coating a trial plate after each addition.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received to the approval of the Publishers, and advertisements are accepted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

### THE TWO EXHIBITIONS.

R.P.S. EXHIBITION at the New Gallery opened yesterday, and may be visited every weekday from 10 to 10 (excepting from p.m.) until October 24. We give on pages 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840, 841, 842, 843, 844, 845, 846, 847, 848, 849, 850, 851, 852, 853, 854, 855, 856, 857, 858, 859, 860, 861, 862, 863, 864, 865, 866, 867, 868, 869, 870, 871, 872, 873, 874, 875, 876, 877, 878, 879, 880, 881, 882, 883, 884, 885, 886, 887, 888, 889, 890, 891, 892, 893, 894, 895, 896, 897, 898, 899, 900, 901, 902, 903, 904, 905, 906, 907, 908, 909, 910, 911, 912, 913, 914, 915, 916, 917, 918, 919, 920, 921, 922, 923, 924, 925, 926, 927, 928, 929, 930, 931, 932, 933, 934, 935, 936, 937, 938, 939, 940, 941, 942, 943, 944, 945, 946, 947, 948, 949, 950, 951, 952, 953, 954, 955, 956, 957, 958, 959, 960, 961, 962, 963, 964, 965, 966, 967, 968, 969, 970, 971, 972, 973, 974, 975, 976, 977, 978, 979, 980, 981, 982, 983, 984, 985, 986, 987, 988, 989, 990, 991, 992, 993, 994, 995, 996, 997, 998, 999, 1000.

Without any pictures of prominently outstanding character. The process is naturally somewhat fully represented, and practically every exhibitor not pledged to a given exhibition is represented. There is a large proportion of work from those who made their debut at the R.P.S. (P. 714.)

The scientific and technical section is largely made up of record photography, chiefly of natural history subjects. (P. 718.)

There are some notable three-colour prints, including one made in Autochrome. (P. 719.)

Autochromes form a separate section, and are shown in the Room. They include certainly some of the finest work yet in this process. (P. 719.)

Professional photography is represented by W. Crooke, H. Walter, and Furley Lewis. (P. 719.)

There is also a collection of photographs of celebrities exhibited in connection to the proposed collection by the Royal Photographic Society of photographs of eminent persons. (P. 721.)

The trade section a display of apparatus and of results obtained with photographic plates and papers is made by a number of the makers. (P. 721.)

The full programme of the lectures to be given, one on each day, during the run of the exhibition, is given on page 724.

THE PHOTOGRAPHIC SALON admits of convenient review owing to the arrangement of the exhibits into a comparatively small number of cases, each representing the work of one man. Autochromes, by E. J. Steichen, A. L. Coburn, and Baron de Meyer, are a strong feature of the Salon. (P. 725.)

PRINTING NOW AND TO COME.—Mr. F. C. Tilney, in discussing the place which the oil process is likely to occupy in the future, says that it will range itself with such methods as gum and platinum, which enable the photographer to exercise a large degree of what constitutes art. (P. 711.)

YEAR'S PHOTOGRAPHIC PICTURE-MAKING.—Mr. Snowden Ward says that the pictorial harvest of 1908 is containing "not too much of the very highest class." The output of the thirty or forty who may be acknowledged as in the front rank is closely followed by a large volume of pictorial photography which comes up to the standard of the leaders. (P. 710.)

## EX CATHEDRA.

### Congress, Gala, Tea, and Fireworks.

A prospectus which is not without a vein of unconscious humour reaches us in respect to "the great congress of photographers" to be held on Saturday, Sept. 26, at the Franco-British Exhibition. On this day, we learn, special concessions will be granted by the Exhibition authorities in the way of reduced charges for admission to the grounds and to the side-shows, and of free permission to photograph. These are obtainable through the organising secretary of the "congress," Mr. E. R. Human, 43, Whitta Road, Manor Park, E. To what extent the "congress" will bear out its dictionary meaning of "conference or friendly meeting for discussion" must be judged from the fact that the function is limited to about one hour's duration, during which time four addresses are to be delivered personally or by proxy. Mr. T. E. Freshwater is announced to take the chair at 7 o'clock in the Congress Hall at the head of the Court of Honour, though the prospectus leaves us in the dark as to the precise purpose of the meeting. There is the expressed anticipation that it will be the largest meeting ever held in connection with photography, but, so far as we can discover, no reason is assigned, beyond a possible economy to the amount of 3s. 5d. (what you save on the side-shows), why it should not quite appropriately be the smallest.

\* \* \*

### Backed Plates for Reproduced Negatives.

The importance of backing plates in reproduced negative making, whether the same size or enlarged or reduced, can scarcely be over-estimated. In a camera exposure the use of an unbacked plate may result in a little degrading of the shadows, and this may pass almost unnoticed, or in certain cases may be actually an improvement. But when this degradation is doubled between the original and the final reproduced negative, a loss of quality is sure to become apparent. The backing is so easily applied and so easily removed a few minutes later, when the exposure has been made, that no excuse can possibly be found for omitting the application. Where a negative is being made by contact from an enlarged positive, a printing frame being used, it is necessary to protect the pad of the printing frame from the wet backing, and for this a piece of plain black or dark brown paper should be used, free from any printed matter or attached labels. If the backing is applied very thickly this unevenness of tone on the protecting paper might be unimportant, but should there be only a thin coating, or thin patches on the coating, the light passing through the plate will be unevenly reflected, and an image formed of whatever there may be of pattern or printing on the sheet of paper used. The experiment may be tried by placing an unbacked quarter-plate behind a fairly soft negative, and then

between the plate and the back of the printing frame a piece of ordinary bold type newspaper. The proper exposure given and the plate developed, it will be found on examining the resulting transparency that the type will be distinctly legible.

### Enlarged Negative Making.

We recently came across a worker who complained that he could not get good enlarged negatives when working in the dark-room with a projection lantern. His negatives made in the camera by daylight were quite satisfactory, but his condemnation of the alternative method, which he found a satisfactory method when using bromide paper, was strong, and it seemed to us quite, unreasoning. An almost momentary investigation revealed the reason of his non-success, and afforded an excellent example of that lack of thought which so often characterises workers who have, unfortunately for themselves, been trained by rule-of-thumb methods, or in the so-called practical way. The easel was covered with white paper for convenience in focussing, and to this the bromide paper had always been pinned. When the enlarged negative was being made the plate was fastened up in the same way, resting on large drawing pins. Had this worker bought a dark slide, the metal division of which was painted white, he would have immediately realised that his plates would be degraded by

reflected light, but the familiarity of the white easel vented his giving the matter a thought. As soon as the paper was substituted for white, the focussing being on a white card resting where the plate was to be subsequently placed, the trouble ceased, and the negatives as clean as could be desired.

### Receptacles for Alum and Other Solutions.

A correspondent who, as a camera worker on a considerable scale, employs fairly large quantities of alum solution asks our advice as to the most suitable vessel in which such solution may be stored. Per other readers as well as he may be glad of a hint as to convenience in this respect of the so-called "acid jars" made by Doultons, of Lambeth. They are stone pitchers, are cheap, and very strong. They are made in different sizes, holding from half a gallon to three or four gallons, and have a handle, so that they can easily be carried about without spilling the contents. These vessels do not seem to be very generally known amongst photographers, but they are very excellent for all solutions, as hypo, alum, bichromate of potash, and the like. They are also very useful to those who save their silver residues on a small scale, as, being tall, the residue settles perfectly at the bottom, and the supernatant liquid is easily poured off without disturbing it.

## THE YEAR'S PHOTOGRAPHIC PICTURE MAKING

[The following short general review of the work of the year in pictorial photography gains in importance from the fact that it is by Mr. H. Snowden Ward, who, as editor of "Photograms of the Year," enjoys quite exceptional opportunities of seeing work which may or may not reach the exhibition walls. Mr. Ward, in his annual miscellany of photographic pictures, makes a selection more comprehensive and more catholic than perhaps any committee can make and hang, and, therefore, while awaiting the publication of the reproductions produced under his care, it may be useful for the reader to compare his general impression (described below) with the collections which obtain publicity at the Royal and Salon.—EDS. "B.J."]

THE Editor asks me for a forecast of the season's pictorial work, and in many years, writing at this time, before the first Press view, a forecast would have been fairly easy. This year there are distinctly disturbing circumstances. Thousands of the year's pictures, including hundreds intended for the shows, have passed through my hands; and without much doubt I might name a number that are pretty sure of being accepted. But much of the most interesting work of the year is beyond the ken of "Photograms of the Year," because it consists of Autochromes which we do not attempt to reproduce. Every one knew that these wonderful one-plate natural-colour transparencies were to be special features at the Royal, and now we have discovered that the Salon had an Autochrome sensation up its sleeve. Without much doubt the entry of the colour-record into the arena of art is to be the great feature of this year, as its triumph in the technical field marked the season of 1907.

To a very small extent the Autochrome show at the Salon has been discounted, for those who are in the centre of photographic activity, by certain private and semi-private exhibitions (as at the Lyceum Club) and by the reproductions in "Camera Work." The reproductions in the special number of "The Studio" have been open to the general public, but have not been quite good enough and striking enough to give an idea of the full achievement of the best colour men. The very fine Autochrome show at the Franco-British, again, is too technically triumphant to prepare one for what has been done and what is being shown at the Salon and the R.P.S.

While the Autochromes that should be shown this year will answer completely the argument that they must be hard, mechanical transcripts, they will also show to the critical observer that photographers will need to take up the study and the close observation of colour, for most of them are

floundering in dissonances and crudities that are just as hurtful as the monochrome falsities of tone and awkwardnesses of line and mass that were almost universal until a very few years ago. Probably the greatest real benefit of the Autochrome for the time will be its influence upon the tone-rendering of our monochrome prints, for many a man who does not seem affected by the harmonies in the natural landscape he photographs will be able to learn much more studying colour-transcripts.

Multi-colour gum has produced some startling work, and it will be interesting to note how much has been accepted. Instead of it, hung as most wonderful experimenting a year or two ago, should be rejected nowadays. The work that I have seen this year shows little advance in colour value, and the time will soon come, if it has not already arrived, when we must find that a picture in colour shall be at least as harmonious, pleasing, and true as it would be if executed in monochrome. The "house exhibition" of the Hofmeister and Müller work, from the point of view, will be more interesting than the great Salon, and many of its things can only be justified as magnificent experiments, not as pictures.

In monochrome the very wealth of material presents an enormous difficulty. There is not too much work of the very high class—in fact, photography has still far too little of original observation and spontaneous effort. But coming close to the thirty or forty men who may be considered great individuals, there is a mighty press of people doing good scientific work—even inspired with a modest inspiration—much must be rejected that will be quite as good as what is accepted.

The Americans, who are submitting largely, and who are joining the selecting committee of the Salon this year, may be expected to be largely represented—too largely, I fear, for the real good of photography. But that is politics beyond

Arbuthnot has more than maintained his position; Bland has done one thing—a great picture; Craig Annan, Keighley, Mummery, Furley Lewis, E. O. Hoppé, the Warburgs (especially Miss), H. Walter Barnett, and Speight, Frederick H. Evans, Mrs. Barton (more varied longer than ever), E. G. Boon, Mrs. Jeanne E. Bennett, and Mrs. Bracewell, A. H. Blake, Walter Benington, the Archibald Cochrane, F. H. Cliffe, Demachy (tackling complex problems than ever), Dührkoop, Dan Dunlop, Meyer, Gear, Dr. Grindrod, Aubrey Harris, Hensler, Ing, Inston, Charles Job, Kimber, Dr. Lynam, Marshall, Mer, Mahéo, Ward Muir, Miss McKeggie, Puyo; Miss Ford, Fred Radford, W. Rawlings, W. A. Stewart, H. Y. ons, Ward-Thompson, Mudie Thomson, W. Thomas, E. B. es, Percy G. R. Wright, Miss Willis and John M. White—amongst those whose names occur to me as being pretty acceptance if their work be submitted, for the old ones will well maintained their positions, and the new names some who have well proved their quality.

There are many who, a day or two before the receiving days, were uncertain or were not sending. Mrs. Käsebie and Percy Lewis are submitting nothing. Mrs. Caleb Keene, whose work is magnificent this year, just missed the Royal, I believe, by a misadventure at sending-in time.

Beyond our own shores, Germany stands still with grand achievement, but no notable new work or workers. France is much the same, save for a few Autochromes. Australia, Spain, Canada, and the Americans outside the Secession are unusually strong, and full of further promise, but much of their work will not go to the exhibitions. The Secession itself, after an absence of a year from English galleries, has much to show; and if political strings pull as I anticipate the Salon should be one of the very strongest for many years, but with a slaughter of some German, French, and British work which even so strong an exhibition can ill afford to lose.

H. SNOWDEN WARD, F.R.P.S.

[The above was written before the opening of the exhibitions. —Eds. "B.J."]

## OF THE FUTURE OF OIL PRINTING.

STION has been raised as to the legitimacy of classing oil—amongst photographs in an exhibition. It has been t by some that the people who are able by extraneous is to carry pictorial effect beyond the limits of a purely graphic image enjoy a somewhat unfair advantage over who are limited to the older and narrower resources. There ibly a righteous grievance here; but, for my own part, I it to be theoretical rather than practical.

The first place, no one can expect the promoters of exhibi- to cast out attractive works upon such a score, for it is st concern of a hanging committee, artistically and finan- that a roomful of pictures shall stimulate the emotions se who come to see it. In the second place, it may be d whether oil prints or "bromoids" can be invariably ed, especially when they are what is known as "straight." is less and less tendency to describe in catalogues the al variety of prints: the custom is more than ever to ll such technical matters in the larger consideration of al efficiency. If pictorial photography is to advance urther there must be no objection to the growth it custom. Moreover, it is practically impossible to the line at a point where control begins, for its work may nce at any stage in the making of a negative, and be car- n to the last touches upon a print. The only point n "pigmenting" differs from any other kind of control ere handling of the brush, which to some is easy and to embarrassing.

war I should be inclined to wage on behalf of non- uters would be in the cause of their reputation for artistic t should not come to be thought that one who develops age by the brush is necessarily possessed of more artistic e than one who does not. The idea should be combated ver it occurs. A man who can pigment well can do so in nce of the very ABC of photography; yet if he were a photographer he could use any other method of control, s gum-printing or local development in platinum with success. I do not imply that such methods would require than a few moments' instruction to the average intelli- t; but still, they do come within the pale of photographic calities, whilst pigmenting does not, and therefore the nter may be—as in my own case—no photographer in the r definition of the term. If I were a photographer I e I could make a show with gum; and, indeed, I have y amused myself with glycerine upon a platinum print.

Mr. Inston and Mr. Sinclair are clever pigmenters; but they are clever photographers also, and their successes are not due to any power denied to a photographer as such. If a man has artistic feeling he does not need a brush and pigment to demon- strate the fact. These arguments I adduce to substantiate my opinion that if there is an objection abroad as to pigmenters having an unfair advantage, it is purely a theoretical one with- out practical confirmation.

I know of one or two pictorial photographers who have attempted oil methods and discarded them after a short trial. Probably countless others have done the same with gum. What does that imply beyond some purely physical difficulty in the means of expression?

The "extra rope" that oil-printing affords may certainly be found in the capacity for repairing the misfortunes caused by unhappy conditions in a negative; but the older methods are not closed against such reparation, and at the worst who shall say that the destruction of an unsatisfactory negative and the making of a better is not as artistic a course as the vamping up of a print from it?

From examples that occur with more and more frequency one must admit that, as often as not, oil-printing is a delusion and a snare to many who dabble with it for the sake of some imagined distinction it carries. The force of its colour sometimes obsesses the aspirant who produces stodgy tracts of printer's ink that give the lie to all the delicacies and subtleties of real artistic work. Oil printing is not a magic process; it is not a short and easy cut to art. He who has not observed and learnt and given himself artistic polish will find it of less use to him than the methods he has become accustomed to; but to him upon whom art has laid her blessing oil-printing offers more convenient ways of arriving at a desired effect than do the other methods of control, and that is all about it.

Its future is probably that of gum-printing, glycerine-platinum, and all the rest. It will be a favourite with such as it suits, but it will never hold the field pre-eminently.

I do not believe that any body of men organising an exhibition will regard it as a class of work outside the pale of photography. There is no place for a distinct class between photo- graphy which is reproductive and dependent upon applied science and the graphic arts which depend only upon the eyes and the brain of the artist. That is the ultimate classification. Fingers and apparatus do not count for much in the matter after all.

F. C. TILNEY.

## THE ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

YESTERDAY the New Gallery opened its doors, and daily, from 10 to 10 at night (closed, from 6 to 7), until October 24, the public can see for itself a really great and comprehensive exhibition of many important branches of photography. A description of its four sections makes rather large demands on our space, but this year we have nevertheless departed from our usual practice of treating one section only in an issue. Instead, we present a complete review of the whole exhibition, together with some photographs of the selecting committees, and a portrait, taken on selection day, of the untiring secretary, Mr. J. McIntosh, to whose Scottish persistence and judgment a very large share of the success of the R.P.S. enterprises at the New Gallery must be ascribed. Perhaps the portrait conveys more of the "holy calm and quiet of faith's serene repose" than one looks for in an

organiser such as Mr. McIntosh, but then the harvest of what had on that day been gathered in, and the secretary might have had a justifiable breath before passing to a breathless fortnight of hanging and cataloguing.

Our review of the exhibits follows almost exactly a tour of the rooms, made as follows:—

Pictorial Section—West Room.

Technical and Colour Section—Gallery and North Room.

Professional Work—South Room.

Trade Exhibits—Court and North Room.

Not only so, but in each section we have endeavoured to make the hanging arrangement, in order that the reader may be able to mark any items which he thinks will specially interest him and inspect them conveniently on visiting the New Gallery.

W. R. Bland. Furley Lewis.

J. McIntosh (Secretary).

E. I. Holding. C. F. Inston. J. C. S. Mumery. G. A. Storey. R. Gay Wilkinson.

### THE SELECTING COMMITTEE IN THE PICTORIAL SECTION.

*Photographs by T. C. Turner and Co.*

SOME brief, and, for the most part, perfectly accurate particulars of the members of the selecting committees may be jotted down in telegraphic fashion for the sake of those who may not know the men personally. They may assist readers and exhibitors in estimating the factors which have made the exhibition.

Whatever may be said of the committees—and such honorary bodies are always a target for the malcontents—they cannot be accused of pushing themselves forward. Their individual support of the exhibition is rendered as private members. They,

like previous Royal committees, command the confidence of the exhibiting world for their single aim at producing a show which, in their judgment, is the best possible material submitted.

### The Pictorial Committee.

W. R. BLAND.—By nature, as by name. Slaved for years for straightforward photography; as probably done less work than anyone of equal record, average about two p

ar. Has confessed to a reverence for moorland scenery and  
ro-ammonia.  
E. T. HOLDING.—Strenuous, quixotic in ethics. Only five  
ers a photographer, but has kept to home portraiture:  
grand piano, his forte: prints in platinum, and though not a  
downer, is an advocate of small holdings.  
CHAS. F. INSTON.—A Northern light of unusual brilliance  
perfect aw roarer); of anti-American persuasion. Gets all he  
n in the negative: has hitherto printed in bromide or platinum  
the latter sepia by a method of his own), but now champions  
for its richness of quality more than for possibilities of  
fake." A lover of the fine arts and something of a collector.  
FURLEY LEWIS.—Formerly crucified his artistic tastes in three-  
four photo-engraving. Now maker of photographic portraits  
ini-privately. A photographer of men chiefly. Picturesque,  
ebane, accomplished, "He held three lilies in his hand."—  
ossetti (with apologies).  
J. C. S. MUMMERY.—*Suaviter in modo, fortiter in re.* Chair-

DOUGLAS ENGLISH.—Represents natural history photography  
at home; friend of wee tim'rous beasties, and moves a good  
deal in the upper circles of reptile society.  
C. E. KENNETH MEES.—Scientific director of Wratten and  
Wainwright, and author with Dr. S. E. Sheppard of some light  
reading, entitled, "Investigations on the Theory of Photographic  
Processes." Under 30, but a recognised authority on photo-  
chemical and sensitometric matters. Frankly critical but  
enthusiastic, and babbles of panchromatics and isocyanines in  
his sleep.  
A. J. NEWTON.—Principal of the Bolt Court School of Photo-  
engraving established by the L.C.C. Almost the only indepen-  
dent authority on modern photo-mechanical processes. A severe  
critic of ways and processes put forward as new or intended to  
be practically better, yet quick to appreciate genuine progress.  
JAMES A. SINCLAIR.—Apparently on the committee in the  
interests of technically good photography, of which years ago  
he was an exhibitor. He now pins his faith to "straight" oil:

E. J. Wall.

A. J. Newton.

J. McIntosh (Secretary).

Jas. A. Sinclair

Douglas English.

J. Waterhouse.

Conrad Beck.

C. E. K. Mees.

THE SELECTING COMMITTEE IN THE TECHNICAL SECTION.

At the hour of taking the photographs Messrs. Sinclair and C. P. Butler could not be present. A portrait of the former is inset on the right.

man of the Hanging Committee by virtue of his presidency of  
the R.P.S.; also of his personal labours in the West Room.  
has not forsworn gum for oil.  
B. GAY WILKINSON.—Friend and pupil of the late Colonel Gale  
and a member of the ancient and exclusive "Field Club," in  
which Colonel Gale was a moving spirit. A landscape photo-  
grapher, chiefly of pastoral scenes, and a consistent exhibitor at  
the Royal for many years.  
G. A. STOREY.—Associate of the Royal Academy and painter of  
cabinet pictures of the old school, genre, and latterly chiefly of  
mythical and legendary subjects.  
**The Technical Committee.**  
CONRAD BECK.—Scientific head of the optical firm which bears  
his name, and lecturer and writer on both popular and recondite  
sides of optics.  
C. P. BUTLER.—Of the staff of the Solar Physics Observatory,  
South Kensington, and a specialist in optical and photo-chemical  
methods in solar and astronomical research.

holds the record of four successive R.P.S. medals, and has only  
now returned to exhibition activity. A connoisseur of Auto-  
chromes, of which he has made some of the best examples.  
E. J. WALL.—A living encyclopædia of what has been done  
and published in technical photography, and in particular in  
colour photography. Supposed to know the greater part of  
Eder's "Handbuch" by heart, and to be able to quote  
chapter and verse respecting anticipations of alleged original  
work.  
MAJOR-GENERAL WATERHOUSE.—A unique experience and  
knowledge of photography and photo-mechanical work for civil  
and military purposes. The authority on obscure phases of  
photographic history and on half-explored fields of photo-  
chemistry.  
We may now pass to a detailed review of the exhibition, after  
again reminding the reader that, with the exception of the  
hour from six to seven p.m., the New Gallery is open every week-  
day from ten to ten, until its closing date of October 26. The

gallery, it may be added for the benefit of country visitors, is numbered 121, Regent Street, stands almost exactly opposite to the premises of the Stereoscopic Co., and is about equidistant

between the Oxford Circus Station of the Central London and Bakerloo Tubes and the Piccadilly Circus Station of the Bakerloo and Piccadilly Tubes.

### THE PICTORIAL SECTION.

THE Exhibition of the R.P.S. presents very much the usual appearance. There appear to be more pictures on the walls than usual, though we believe there are really fewer than last year. At the risk of disappointing still more aspirants we should advocate a more rigorous selection. It seems to be beyond the occasion that men having two or three excellent works should be further represented by others of less merit. Even if the space were not filled up by such omissions, the gain in the general effect would be very considerable. We notice a tendency to the old white mount of earlier days; the effect of this is somewhat disquieting when they are mingled, as they often are, with close-framed works of a dark appearance, or with dark mounts. A classification according to colour would, in our opinion, give the Gallery a finer effect.

We shall review the work strictly in order of the catalogue, but it will be impossible to adopt any method of grouping by subjects, names, or titles. For the sake of convenience in comparing our notes with the actual works, we shall paragraph this critique according to the panels which are quite easily recognised in the Gallery.

Entering the West Room by the left-hand door, we come first to

#### The East Wall—Right-hand Panel.

From this group No. 13 stands out as the most effective and most pictorial. It is entitled "The Salmon Leaps," and is by Mr. Louis J. Steele. The rushing of the water over the rocks is given with fine movement, and there is a sort of vaporous atmosphere over all, combined with an effective lighting natural to an over-shadowed stream, making this picture both naturalistically and pictorially a remarkable work. "Dovedale" (1), by Mr. C. F. Stuart, has a good deal of grace of composition and a nice effect. The portrait of the famous "Walrus" (2) by Mr. J. Smith, will be recognised with pleasure by those who know the sitter, and with great satisfaction of curiosity by those who do not. It is an excellent portrait, giving the man to the very life, and is treated throughout with fine taste. Miss Maud Geraldine's "Chillon" (5) is a very pleasing version of a somewhat hackneyed subject. "Swarthy Cheeks and Bold Black Eyes," etc., is the title of Mr. H. E. Corke's triumph (8), which we remember to have seen at Birmingham last year. It has the somewhat slight defect that we pointed out on that occasion, namely, a bright spot on the left wrist where the flesh is in juxtaposition with the garment. Possibly this is the identical print. "The Girl and the Kids" (9), by Miss Kate Smith, has a very charming pastoral feeling. It is not often we see the nude figure treated so ideally. "Soliel Couchant" (16) is remarkable for a wonderful sunset sky; in fact, this must be supposed its chief motive, for the landscape in other respects lacks several qualities. The whole effect, however, is distinctly pleasing. In "Vita Antica" (17) Count von Gloeden gives another of his classical compositions. He is to be congratulated upon the skill with which he employs the figures of undressed Italian boys, posing them in a setting remarkably free from incongruous factors. This picture, however, is greatly in need of simplification and concentration. In "The Old Squire" (21), by Mr. C. Friend Smith, we recognise old Mr. Riches, the famous artist's model. The photographer has done remarkably well with him.

#### South Wall—Left-hand Panel.

A new name to us is that of Mr. W. V. Goulstone, and we think his picture, "Calm" (31), takes first place in this group. It appears to be quite pure and "straight" photography and is an excellent example of what pictorial charm can be secured

by such means alone. The relative tones of this, though subtle as almost to result in flatness, give, nevertheless, the utmost relief, and the aerial perspective is one of the charms of a very beautiful picture. The portrait of Frederick Hollyer (35), by his son, F. T. Hollyer, leaves nothing to be desired. It is full of character and fine qualities. "A Still Sea" (39), by Frank W. Becken, has many of the charms of "Calm" of which we have just spoken; but its subject is no means so pictorial, its tones being too equally disposed from right to left, and it lacks atmosphere. "The Wool Washer

The Man behind the Exhibition.  
Mr. J. McIntosh, Secretary of the Royal Photographic Society.

(38), by Mr. F. J. Mortimer, is a capital subject, but surely much overloaded with dark pigment. The tones are probably in perfect relation; but why should they be taken in such a low key? "The Old Garden Gate" (33), by Aubrey Harris, a piece of outdoor genre work, is charming in subject, but, usual with most photographic pictures, too much is included. The figures and the gate, with their pretty, sunny effect, we all that was wanted for completeness, and the tree on the right, together with the accent it makes, is quite redundant. Miss Hilda Stevenson, in the title "Veiled Sorrow" (29), has, we fancy, been making a virtue of necessity. We do not find the subject of this excellent portrait more than interesting and mournful. It appears to be an oil print. If that is so, it is an excellent one. We like very much the "Village Evening" (26), and we should do so still more if the square patch of sky at the right-hand top corner had been lower in tone.

**South Wall—Centre Panel.**

Mr. James C. Batkin's picture, "While the Daylight Lasts" (0), quite deservedly occupies the place of importance in this group, and its title gives satisfactory occasion for the general darkness of the print. The immensity of the great hull overhanging the men has a fine impressiveness. Beneath it hangs "Slow Blush the Breaking Clouds" (51), by B. Ward Thompson. This is very charming, as most of these things are by this careful worker. We are just a little doubtful whether he is wise in limiting his methods and subjects so rigorously. His works in this particular manner have a very strong family likeness. In this we note with pleasure an increase of feeling and a more artistic treatment of edges than in former examples. "La Sereade" (40), by A. and M. E. Bracewell, represents a damsel peeping out of her bedroom window in order to recognise a renader. It is quite evident that the action takes place in twilight, which is not according to the traditional custom of renaders, but undoubtedly suits photographers better. The tin rug at the dressing-table would have been better omitted. It gives the lady the appearance of standing on a hassock, and entails awkward lines parallel with the picture edges; otherwise, the work is quite a pleasant pictorial achievement. Mrs. A. Barton has adopted a new style in "Morning" (54), and we are very happy to see it. Is this charming little figure who is putting on her slipper the same little lady whose head and bust we have so often seen? If so, we are glad to make her further acquaintance. She stands at a chintz-covered dressing-table, in a pretty dress, in a quaint bedroom with leaded lights in the windows. We could have wished there had been more strength of effect, and we have an idea that the nebulous chest drawers and the awkward piece of ceiling above it would have been advantageously trimmed off. Dr. A. R. F. Evershed's "Rochester" (45) is a view across the Medway with a barge in the foreground. It has the makings of a fine composition, but is not perfectly satisfactory as it stands. The sail breaks harshly across the surface of the river, which is in any case too bright. "Sunlight and Flowers" (46) Mr. Ernest G. Boon gives us a similar motive to his pretty diabolical subject at the Salon. This perhaps not quite so charming in action, but its sunny brilliance is distinctly refreshing. "The Tug" (49) by Mr. B. C. Dickson, is a good instance of concentration of dark and light to make a good effect. Dr. Schrakamp's "Rothenburg" (56) is a highly picturesque old German doorway. It appears to have attempted at pictorial treatment, but its intrinsic charm and sympathetic rendering make it quite interesting as a picture. "In the Moselle Valley" (58) is a highly pleasing view with mountains in the background instead of sky. We can see the sky line by reflection in the water, and this sky line has been used by Mr. Wastell to great advantage and with much cleverness to complete the plan of composition in the foreground. "The Dock" (60), by Mr. C. F. Inston, shows the photographer's five town to the best possible advantage. This little oil painting has all the delicacy of a platinum print, and a degree of richness and feeling mostly beyond the powers of that method. It might suggest that the buildings and ships on the left could have been a trifle lighter in tone, so that the barges on the right might have had their own way more distinctly.

**South Wall—Third Panel.**

The portrait of Mr. G. A. Storey, A.R.A. (73), by Bertram Park, is in every way satisfactory, quite rich and strong, but with great delicacy of modelling, and the figure is nicely posed. "A Woodland Pool" (64), Miss K. Smith must be highly congratulated upon having used the nude in open air in a way more charming than it has been our fortune to see in photography for many years—if at all. As a matter of fact, the nude on the figure is so diaphanous as to justify our description of the figure as nude. In itself the figure is highly pleasing in its pose and lighting, and is in perfect balance with its woodland setting. The print is well defined, yet without a

touch of hardness, and no pictorial law appears to be violated. "The Inn of Cervantes" (72) is a very delightful oil print by Mr. James A. Sinclair. We cannot imagine the process in its "straight" method being used to better effect. Of course, the scheme of light and shade in this picturesque courtyard gave Mr. Sinclair fine opportunities. We might say much the same of "Waterside, Chesham" (66), by Mr. Mummery, which is an example of gum printing. Quality is here in liberal measure. The distance is charming, but we think the sky might have been livelier in character. "In the Park" (68) is by Mr. Frank E. Roope. We always welcome subjects of this character, because we consider it a field for which the camera is well suited. We see three nursemaids advancing towards us with perambulators, and a few figures of secondary interest walking or sitting about. The near and distant trees combine to a pleasing lacey effect. The shadows on the ground are helpful in the composition, and the distant classic architecture of the park gateway is also highly pictorial. These things may be found the ingredients of hundreds of similar views lying at the very doors of the amateur photographer, who may often go further and fare worse in the way of excellent subject matter. "In Sympathy" (70) is a curious title for a very bold and effective print of a little girl carrying a baby. The simplicity and force of this capital little study by A. R. Webb give it a highly decorative character. "Sullen Water" (69), by Dr. Pooler, is gloomy and sober, but beautifully composed and highly romantic. "In the Precincts, Exeter" (77), shows a narrow lane and a gateway to good effect. The two figure subjects of W. and J. Parrish and W. Parrish respectively are a little "high falutin'" in the "arty" sense. We prefer "Donna Isabella," because it is less open to this objection.

**West Wall—First Panel.**

"Dispersing the Gloom" (85) is not so effective by a good deal as Mr. Batkin's other work. The gloom does not disperse exactly: but in the matter of composition the picture is quite beyond reproach. "Sunlit" (81), by E. Marks, is effective, but a little hard. "Where Clouds do Nestle" (84) has some excellent points. We like Mr. Taylor's selection, but we feel that the clouds are rather low in tone for the natural effect. "A Glimpse of Dovedale" (90), by Mr. Inston, is better in this respect. It has the effect of daylight, which many a photograph of nice quality and picturesqueness utterly lacks. The bright spot of light upon the mill in "The Mill, Ypres" (86) is quite an inexcusable defect in an otherwise charming subject. Why this accent has been allowed by Mr. James Gale it is difficult to see. No. 87 is a very pretty sunlight effect upon the sea as it rolls into shore. Its title is "As the Sun Throws O'er the Sea a Floating Bridge of Light," and its author is M. Eardley-Wilmot.

**West Wall—Second Panel.**

Of this section we must confess to a predilection for (94) "The Fountain," by A. H. Blake. The old-world grandeur and romance of the fountain and other stone ornaments make a strong appeal. The selection, which has been made with nice discrimination, secures the utmost advantage afforded by the architectural lines. A portrait of Mr. Furley Lewis (95), by E. O. Hoppé, is excellent so far as the face is concerned, but we do not think the pose of the figure has been sufficiently considered with ideas of composition. The two hands, suppressed as they are, are a little obtrusive. There is a nicer pose in "A Wintry Grace," etc. (99), by J. Moffat, where, however, the hands might have been a little less in evidence also. "The Sisters" (101), by E. T. Holding, is a print of very nice quality, boasting a pictorial motive, although it would rank merely as a portrait. "A Bend of the River" (102) is very sweet. Mr. Inston will have to guard, nevertheless, against over-softness in his working of the oil method. In No. 105 we recognise Mrs. Furley Lewis, photographed by her talented husband.

The lady sits in a characteristic pose, and the charm of the print is delightful in every respect. Dr. Evershed's picture "The Young Nun" (107) is a lovely face in a becoming nun's robes. It is a pity that the print is mounted all askew. "In Normandy" (108), Mr. Bale Rider has given us a highly picturesque subject, with a very pleasing variety of tone, rich and bright.

#### West Wall—Third Panel.

This section is full of good things, one of the best being "Isabella en Jan Wilden" (114), by Oscar Hardee, a Dutch man and woman of fine character, and on a large scale. "A Woodcutter's Team" forms the subject of No. 113, by Mr. C. F. Stuart. It is not so successful in composition as many of the works we have seen by Mr. Stuart. Mr. Blake's figure subject "The White Bowl" is a new departure for him, we believe, and he deserves much congratulation upon it. We only object upon principle to the trepanning of the figure, and confess to being unable to see the artistic advantage of such a drastic measure. "Homewards" (117), by Mr. Jas. A. Sinclair, shows two old ladies with white caps crossing the road of a Continental town. The figures are capably placed, and, ordinary as the subject is, its treatment has secured quite a highly pictorial result. Two ladies of different ages compose the "Portrait Group" (124). Herr Dührkoop, its author, understands better than most photographers how to make his sitters intensely interesting, whatever their personalities may be. The elder lady's hand is perhaps not quite a happy item in a print of great charm and quality. "Wedded" (125), by Aubrey Harris, is a very pretty subject, treated in a rather commonplace way. It is perhaps a little too reminiscent of a famous picture which figures on pictorial postcards on the Continent. In "Away Aloft" (126) we have quite a remarkable picture of rigging and men clambering up it. We suppose nothing quite like this has been done before, and Mr. Mortimer has certainly secured the charm of newness and quaintness. No. 132 is another work of Mr. Mortimer's. In this subject the chief feature is the sparse silver birches that straggle across the front. It is called "The Grook Kerk, Veere." The women in cap and bib that figure in it give life to the scene. No. 127 is another of Mr. Ward Thompson's efforts, possessing all the beauties and conventions of his work. No. 133 is a pleasing picture in Bruges, with a sunlight effect, by S. G. Kimber.

#### West Wall—Fourth Panel.

"An Olive Grove" (135) is a very sunny sylvan scene, by T. D. Ralli, full of good points, but a little uniformly grey in the vista. "In Old Caudebec" (146) a view of old houses and shops at the meeting of two streets has been nicely given by R. E. Weeks. It has a pleasing variety of tones. Three ducks in bright sunshine against an old stone wall constitute the whole of the subject of one of the most remarkable prints in the exhibition. If they had been most thoughtfully designed, instead of "snap-shotted," they could not have been more exquisitely posed. The fine quality of the print is eminently noteworthy. One of the best of Mr. Holding's prints is "The Lesson" (144). A lady sits at one end of a small table, and a child stands at the other end. The pattern of the wall-paper and the demure uprightness of the figures combine to give quaint character to a most pleasing arrangement. "Homeward Bound" (146), by R. E. Weeks, is a capital snow scene, the cart in which appears to have runners instead of wheels; a fact that may add an interest to the picture for the average Britisher! "Wareham Bridge" (149), though a trifle woolly in texture, is a capital print by Miss A. B. Warburg; the rich shadows under the arches and the whitewashed gable of the house are fine points. There is a true winter aspect in Mr. Johnston's picture (151) "Winter from Calton Hill, Edinburgh." The monument is impressive and well placed.

#### West Wall—Fifth Panel.

The "Family" in 169 is one of the most charming Dührkoop we have seen. It represents a lady and two children at a piano. The faces are full of interest and charm, and the picture quite spontaneous, though composed with the utmost care. The "Lady in Black" is somewhat similar to the fine example at the Salon, and only a little less good. "A Moorland Hairs" (160) is another of Mr. Whitehead's grey and pleasant landscapes. They always have "mood," but, as in this case, they are rather a little wanting in truth of relative tone. Nos. 161 and 165 by Mr. Inston hang side by side. Both are admirable, and our remarks upon Mr. Inston's other works apply equally to them. The former is a little wanting in strength of effect. In "The Thames" (175) Mr. Gear has quite succeeded in catching the smoky and misty air of London. His view shows a barge passing by the Customs House. "The Kitchen Door" (174) is remarkable for having a rectangular patch of black almost in the geometrical centre of the picture. Still, the work has considerable charm, and the foliage of the trees is managed with much taste and skill. This comes from Arthur B. Clarke.

#### West Wall—Sixth Panel.

In "The Shrimping Ground" (183), by Mr. F. J. Mortimer, we have first of all to take for granted a thick mist having the unusual power of not obscuring the detail. When we have granted this phenomenon, and have approved the central position of the boat, we can then see a deal of nice feeling in the effect presented and in the treatment of the water surface. Nevertheless we are of opinion that a couple of inches off the right-hand side would have eliminated an arid passage of the pigmenting, and would have improved the composition. "The Neighbour" (184), by J. C. Warburg, is a picture of little girls talking to a boy through a window. It has a very pleasing pattern of tones, and the treatment of the print is delicate and firm. A very successful oil printing of an elderly lady reading comes from Rufus E. Evans, who calls it "The Testament" (188). For a foreground study of a nebulous dance, "Weeds," by W. T. Greatbatch, is highly successful. Good romantic feeling and agreeable composition is given by Thomas D. Graly in his "Grey Ghosts of the Past" (185). It depicts a ruined castle with a most effective scheme of light and shade.

#### North Wall—Left-hand Panel.

We like the tone of J. F. Wilde's "Solitude" (170). It is truthful, and none the less pictorial for that. Miss Mary Allan appears in a new rôle in the picture "A Study in Tones" (195), by E. O. Hoppé. She is represented at half-length, and, playing a piano, the lighting of the figure being most effective. Mr. Stuart's "January" (197), though distinctly pleasing as a whole, includes one or two anomalies in tone that rather worry the critical. We think the lights in the sky should have been allowed first place in value, and certainly the high-light on the house are aggressive, though the composition is pleasing enough. An unusually fine quality and effect of light and shade characterises the small print "Misty Morning" (198), by Licinio Farini. In its way it is scarcely beaten amongst the landscapes here. "The Convent Well" (200) shows Mr. Gear at his best. The subject is highly picturesque. We think Mr. Hoppé's portrait of Herr Dührkoop (203) is rather dark and uniform in tone, and the action of his left hand is not well explained. In other respects we like the portrait exceedingly, for we consider that it catches exactly the alert bearing of the famous portraitist. Mr. John McWhirter, R.A., who has likewise proved a splendid subject for Mr. J. Moffat, who, in turn, acquits himself with equal success to his task. Lighting and modelling are excellent. In "A Ray of Light" (206) Mr. S. G. Kimber repeats an old success.

### North Wall—Centre Panel.

picture "Si vis pacem, para bellum" (217) represents a ship coming full steam ahead in what appears to be a night, with the moon somewhere behind the clouds. That is how it appears to us, though we have not Fortimer's word for the actual fact. It is certainly impressive, and well suited with a frame. "Gleam and Grime" is a good picture of some squalid manufacturing town. by James C. Batkin. It is a pity that the chief accent group of figures is so exactly central. Mr. Harold's picture "Evening" (211) is a nicely managed effect of meadows seen through trees overshadowing a brook in foreground. The print is pleasant in colour, and well free from flatness of effect. The high-lights in the "Temple" (215), by Mr. Gear, are almost too liberally equally distributed. Though there is not much evidence of subject in the title of "Radiant Morn" (213), yet it only has the mysterious quality of morning light, and communicates the mood of the effect portrayed. "A Sunny" (218), by the President, gives with a good deal of truth the softness of the light due to clouds rapidly passing. The of dark trees on the right has a good steadying effect on parts that might otherwise be wanting in simplicity. Lay upon words in "Seeing the World" (220) is due to the of a little girl examining a school globe. A point overlooked is here well secured. That is to say, the of the solid article is well insisted upon, and combined with the charming looseness of texture of the fabric of the girl's dress. A reader unacquainted with technical art would find in this fine thing by Mrs. E. Peake ample illustration of that indefinable thing "quality." Simply much mixing together of black and white in various shades, now firm and now melting, this print is an object in the charms of chiaroscuro. "When Johnny Comes Home" (221) shows an animated group waving greet- at a window. This is by Mr. David Murray. The of the coal barge on the mud-flats of Broadstairs given Mr. W. H. Kirkland, the photographer of "Low" (225), a fine theme. A little more gleam upon the shore would have been advantageous. Another excellent print, by Mr. Jas. A. Sinclair, is "Dust and Sunshine, and" (227). The effect implied in the title is well shown. Mrs. Barton understands eminently well how to make a picture. We think, nevertheless, that a little less light in the shadows would have made "Summer" (226) more charming. The hand appears to suffer from enlargement of scale.

### North Wall—Right-hand Panel.

We have no doubt in giving the highest praise in this group to "Sun and Mist" (234), by A. E. King. It is dead true, and could scarcely be more charming as a picture of a "mood." The reticence of its treatment is highly commendable. "Chartres—la basse ville" (233), by Miss Margaret Miles, and "Many Cargoes" (241), by F. W. Jackson, are prints that suffer from an unreality of effect due not so much to a want of power in using the method as to a want of imagination of Nature, and a knowledge of certain unwritten laws in art. Mr. William Pringle gives us a capital scene in "The Arrest" (232), a title which can only apply to the figures that are no more than mere accessories. Mr. J. Meyer, in "Making Friends," has made a picturesque of a boy sitting and watching some hens. He has not more regard for truth of effect in lighting than many others in whom we have deplored the absence of those essentials, yet his picture is agreeable nevertheless in those other things that defy analysis, but which we can only vaguely judge as design and quality. A convincing effect is seen in

"Thaw" (245), by G. Haranghy der Nagyrév, and the imported colour is less objectionable in this case than it usually is. We must not pass over "Ritratto in pieu aria" (238), by Giuseppe Castruccio, which is an extremely charming picture of a lady leaning against a wooden railing. Here again there is design and unusual quality in the sky, added to a breadth of treatment in the light and shade of the figure. "The Kiln" (244), by Sydney J. Taylor, is most effective and romantic.

### East Wall Panel—to left of door.

The most important work in this group represents a sculptor pausing in his work of cutting a life-size figure of a mother and child, and we may say, parenthetically, that the sculpture appears to be an extraordinarily fine one. The artist himself is rather too obviously pausing while the operator does his business. The picture is by Frau Grete Dorrenbach, and is entitled "Im Atelier" (254). Our next favourite is Miss Brenda Johnson's delightful landscape, "A Summer's Day" (256). As upon a previous occasion, Miss Johnson has added much to the charm of her work by the inclusion of a precious little figure, quite small in scale, but efficient in making its due effect. Mr. A. H. Piddington's "Corn Ricks" (250) shows that he has mastered the elusive *sine quâ non*, quality. "Poaching" (249), by Miss Dorothy Ritchie, depicts a dog making off with what appears to be a rabbit. Miss Ritchie has very cleverly enhanced the sensation of movement in the animal by showing more space behind him than in front. This invokes the idea that he is running out of the picture. It is a pity that Mr. George Hilderley has placed his figures so immediately under the mill in his picture "Sunday Evening" (257). This leaves rather an empty space at the left. Another mill of very dramatic portent occurs in "The Harvest that is to be" (259), by Oscar Hardee. The designing of this subject leaves nothing to be desired, unless it be less murk in the foreground; but we are unable to understand what effect of night or day the photographer wishes to depict. "A Paddler" (261), by Percy G. R. Wright, shows us a girl standing on the sands in an inch of water. The picture has a nice effect. The small and single dark accent of the girl's hair gives it a piquant decorative note.

### Between the Doorways, East Wall.

Delightful action of a baby girl holding a sprig of seaweed will be found the irresistible charm of H. W. Rennie's "Water Baby" (263). Miss A. B. Warburg's "Church Parade in Dalecarlia" (264) is lively and interesting. We have next a couple of prints by E. T. Holding, which we feel sure will be highly popular, as they deserve to be. "The Song of the Lark" (265) is the title of the first, and is well borne out by the action of the lady and child, who stand upon a common listening. The other is an interior, showing a window-sill with a couch before it, and about these objects two pretty children are clambering in order to reach each other a kiss. The girl particularly is very charming. The picture is named "Sunshine and Kisses" (266), and is technically beyond cavil. The costly luxury priced at £30 by Cavendish Morton is called "Motherhood," and though beautiful in subject is rather crumbly in texture. "Finis" (268) represents the last remains of a wreck on a romantically dreary shore. This is by Harold Moore. Next we find another variety of the work of A. H. Blake, who has certainly surpassed himself this year. He gives us a young lady making tea at a table flooded with light. Its title is "Early Morning Sunlight" (269). "Etude en Rouge" (271) is a prettily posed back view of a lady's head and shoulders. The fierceness of the effect in "Crescendo" (273), by W. H. Porterfield, reminds us of one of the Plagues of Egypt. We welcome J. C. Warburg's large and important "Notre Dame de Vie. Among the Cypresses" (283) because the exhibition is lacking.

this year in those fine and impressive landscapes of large scale that have in former years lent such distinction to the walls. We believe a slightly different point of view might have obviated the somewhat symmetrical disposition of the church and the trees that flank it, and we do not quite like the light triangular patch at the left side. A clear and bold photograph of a head, entitled "Rosamond" (293), comes from Cavendish Morton, who has seized in this work a choice pose, and given full value to the beautiful hair of the sitter. Another nice pose in a good subject is presented by George Hilderley's "Nelly" (300). No. 303 is a second portrait of Rudolf Dührkoop, F.R.P.S., this time by Furley Lewis. It exhibits this photographer's method of keeping nearly all the light from his sitters' hands—a good plan in principle; but in this case we feel that they do not sufficiently tell apart from the rain cloak that Herr Dührkoop is wearing. As usual, the print is beautifully harmonious. We finish our review of the monochrome prints by noticing two more by A. H. Blake. "In the Court of Honour" (308) he has secured more beauty of lighting and better composition than Mr. Coburn has done in his Salon view of the same subject, although he has not worked in so grand a manner. "Road Up" (309) is artistic to the last degree. We admire the way in which an asphalte boiler, with its great circular lid and issuing steam, has been advantageously made the chief feature of a characteristic London view.

### THE SCIENTIFIC AND TECHNICAL SECTION.

THIS section must be admitted to be somewhat disappointing. There are no exhibits that can be described as of a specially novel character, no apparatus, and no astronomical photographs, with the exception of a few lantern slides. Foreign exhibitors are confined to three, and work of a research nature is practically absent. Indeed it might almost be described as an exhibition of record photography, for nearly all the work shown is of the nature of simple records of facts. An unusually strong and representative selecting committee was appointed this year, and want of confidence in their ability could not possibly be the cause of the abstention of many prominent workers. No doubt the abolition of medals is the real reason, for work of a very important, but probably somewhat obscure nature, has little or no chance of recognition in a public exhibition unless attention is drawn to it by means of an award, and the prospect of one's work receiving no notice beyond the compliment of hanging is not encouraging. It is to be hoped that the R.P.S. will before long see their way to again offer medals in this section.

#### Feathers and Furs.

This is, as usual, the most prominent feature of the technical section. It contains nothing very conspicuous, and the subjects are not exactly new, but some very excellent technical work is shown. Mr. Douglas English is well to the fore with five first-class exhibits (310-314), his representations of stoats, moles, marten cats, and snakes being exceptionally good. These are of very distinct scientific value, since such shy creatures as moles and stoats are seldom to be seen in the wild state, abundant as they are. Mr. Martin Duncan has a fine study of a caged "Crested Harpy Eagle" in 320, and also one of "The Little Owl" in 321, and Mr. William Farren shows his usual skill in tackling very difficult subjects in his studies of the Woodlark and Song Thrush (322 and 323). His sitters are shown in their natural surroundings of bewildering masses of twigs and foliage, and yet somehow he contrives to show us the birds clearly. As he evidently does not descend to any heretical photographic tricks to accomplish his purpose, the only possible explanation of his success is the exercise of great skill in selecting and arranging his view point and in making his exposure at the right moment. Nos. 327 and 328 are very excellent studies of thrushes and owls by Mr.

#### Colour Work.

There are three or four photogravures printed in colours which recall very charmingly the tinted mezzotints of bygone days. These are by C. Percival Small and Co. They will be overlooked, for their colour is attractive in its limited and in no respect violates the hues of Nature. They are all traits, the finest being "Miss Lawless" (278) and "Mrs. Alexander" (282). Certain other prints in coloured oils, with one exception, no advance in photographic matters, feeling after effects that can only be moderately successful—a gigantic tour-de-force. The exception is the "In Spinner" (298), by J. C. Warburg and F. T. Hollyer, which has been achieved by a purely photographic process of which the details are as yet undivulged. This is in some parts highly successful. We cannot say as much for the other colour examples—mere oil prints in multi-colours. To our mind they are turgid and stodgy, and absolutely without truth to Nature. Whatever there may be that is pleasant to some in the colour of these attempts (and we find nothing) must be attributed to accidental admixtures of pigment, having no logical connection with the subject matter. The topographical obligations of certain well-known views, and the obvious requirements of natural phenomena in certain other landscapes, stultify, if they do not make ridiculous, the colouring of these over-ambitious works.

Alfred Taylor, and next this exhibit Miss E. L. Turner "Ruff" fame, once more distinguishes herself by some remarkably good studies of Stonechats, Whinchats, and a Wren, some way or other she contrives to use or form a background that throws up her sitters to perfection. Mr. William Bidton shows an equally successful selection of backgrounds in his very fine set of photographs of the "Roseate Tern" (324). In the rest of this part of the technical section, Mr. O. Pike shows some good studies of foxes and badgers, while Neville Kingston has secured some exceedingly well-lighted representations of polar bears. None of the other exhibits for special comment, though all are of a high standard.

#### Miscellaneous Subjects.

We next come to the photographs wrongly described as micro-photographs by one exhibitor. Mr. W. F. Cooper's low-power magnifications, shown in 349 are exceptionally good, while Mr. Martin Duncan's frame, showing the insects responsible for the transmission of sleeping sickness and other diseases, is both good and interesting. There is some fine technical work among the examples of photomicrography, but the subjects in many cases are hardly popular ones. There is, however, a considerable amount of interest attached to Mr. A. E. Smith's photomicrograph of Genuine Mushroom Ketchup (362), for in a footnote he informs us that the minute spores, or seeds, found in the genuine article are selected to be seen in commercial samples!

The radiographs are very few, but those of Messrs. Wilson and Blackall, in frame 363, showing the osseous development of the bones of the hand, are of great value and interest. Near by we come to some very fine photographs by Mr. J. Finlayson, illustrating Typical Wheat Ears (365), and Poisonous Plants and Seeds (366). These are not only good technically, but of considerable educational value, while in 365 the author has adopted the truly scientific method of photographing a scale alongside his subject. It is to be regretted that this expedient is not more universally adopted; but fear that some workers attach undue importance to the appearance of things, and look upon plain matter-of-fact scales as intrusive.

The flower studies require little notice, as they are particularly strong. Nos. 370, by Mrs. Dunlop, and 385,

Mr. Ed. Seymour, are the best, while 377, showing "The Pride of Table Mountain," is very interesting.

Dr. Vaughan Cornish exhibits an historically and scientifically valuable series of photographs of Panama Canal in Nos. 393 to 402, and Dr. Tempest Anderson shows some similarly valuable records of the Craters of Santa Maria, Guatemala, and Montagne Pelée. These are to be found in Nos. 403 and 404.

Captain Owen Wheeler, in Nos. 413 to 416, very fully illustrates what an experienced worker can do with the telephoto lens. Very fine definition is secured, even though complete photographs, made with a magnification of 9 diameters, have afterwards been further enlarged four diameters.

No. 420 is an exhibit of rather special interest, as it is a cardboard model of a "Lens Calculator," designed by Mr. A. Lockett. It is very simple in design and easy to use, and should prove useful, especially to those who dislike or do not understand mathematical formulæ.

Another exhibit of special interest is that of Dr. R. A. Reiss, Nos. 425 to 431, illustrating the detection of forgeries and the value of finger prints. No. 426 is remarkable, as it shows that the litho stone used for the manufacture of some forged notes retained, even after regrinding, records of the notes that could be photographed, and also equally definite records of a catalogue subject, printed on the stone twenty years previously.

An interesting feature in the monochrome portion of this section is an autographed portrait of His Majesty the King, by the Swan Electric Engraving Company. This is to be found at the opposite end of the balcony and among the portraits belonging to the R.P.S. portrait collection.

### Colour Work.

In this year's exhibition the Autochromes and colour transparencies are in a section by themselves, and do not form part of the technical section. It still, however, includes the colour prints, and first among these we meet with No. 431, a direct photograph in colour of the solar spectrum by Mr. C. P. Butler. This is a Uto print, remarkable for the fact that it was made in July, 1907, and shows no perceptible degradation even though mixed. The colours are brilliant, and even though the result may be deficient in the pure red, pure green, and pure blue portions, yet as a whole it is really a very good representation of the spectrum. Nos. 432 and 433 are very good though rather small tricolour carbons by Achille Carrara, while Nos. 434 to 445 are pinatypes by Messrs. Meister Lucius and Gruning, Ltd. Among these we may specially notice Nos. 434 and 435, both portraits, and No. 437 is also worth mention on account of the good blacks shown in it. The rest of the pinatypes are all very good specimens, though they indicate that pure whites are not very readily produced. They generally tend to an ivory tint, which is by means displeasing in some cases, but not always desirable. No. 446, by Mr. W. Rayner,

is very well worth study, as a reproduction of Autochromes by Mr. Warburg. Mr. Rayner has been very successful with such reproductions, though it is by no means easy work. Mr. Samuel Manners shows excellent examples of the process that he alone works with such success. No. 449, "Roses," is a good example, while No. 450, "Peaches," is certainly the most realistic piece of colour work that we have seen.

### Lantern Slides and Transparencies.

Some verascopes in the balcony contain specimens of stereoscopic transparencies in monochrome and colour by Mr. Leo Finot, but the most interesting exhibit is No. 687, which contains a series of stereoscopic radiographs of molluscal shells by Dr. G. H. Rodman. These are novel, and some of the results show very beautiful complexities of structure. The rest of the transparencies are downstairs in the North Room. Those in the base of the lantern stand are rather few in number, but of good quality, Miss Kate Smith (Nos. 456-459) and Ellis Kilsey (Nos. 460-466) showing some excellent pictorial lantern slides, and Walter Plomer Young a valuable series (Nos. 467-484) illustrating monuments of all ages. A few astronomical studies by C. W. Barlow are in this stand, together with some which illustrate natural history subjects by Arthur Frost and John T. Roberts. Some stereoscopic transparencies of microscopic subjects, by Arthur C. Banfield, are worth attention, but perhaps the exhibit of most interest is the series of balloon photographs made by Dr. Lockyer. These are all London subjects, and are all worth careful study, especially the one showing the Tower Bridge and the series of waves produced by a passing steamer.

### The Autochromes.

Unfortunately the stand on which the Autochromes are to be shown was not quite finished at the time of our visit, and it is impossible to fairly criticise a number of transparencies when each has to be inspected separately in the hand. We must therefore postpone a full notice of these, but we have seen enough of them to convince us that the collection, as a whole, is remarkably good. Mr. H. O. Klein has a very fine set, including portraits, scientific subjects, and in particular a study of jewellery, in which the lustre and beauty of the precious stones is most perfectly rendered. Messrs. Walter Barnett, W. Partridge, Ellis Kelsey, J. C. Warburg, Imre Belhazy, Rowland S. Potter, and U. M. Jones show some very fine pictorial subjects that will appear to much greater advantage in the proper viewing frames. Very interesting and perfect Autochromes are also exhibited by Dr. G. Drake-Brockman, his series illustrating the evidence given in a murder case being unique and interesting. Scientific and Nature subjects are strongly represented, Messrs. E. J. Bedford, Arthur C. Banfield, J. Inderwick Pigg, and F. Martin Duncan being prominent exhibitors.

### THE PROFESSIONAL SECTION.

owing to the fact that the number of exhibitors is smaller than in previous years, while the number of prints shown by each exhibitor is greater, the walls of the South Room present a more homogeneous appearance than in former years. In the purely professional portrait work shown by Messrs. Furlay Lewis, William Crooke, and Walter Barnett, we touch, of course, the high-water mark in commercial portraiture. Nor does the use of the word *commercial* be taken as implying work which is saleable without being artistic. Any detailed account of each exhibitor's work would be purposeless, and the interests of those professional workers who visit the gallery with serious intent will be better served if the general characteristics of the three displays are outlined, and then possibly one or two individual works more particularly referred to.

The work of Furlay Lewis is marked by strong characterisation of the pose of the figure, the set of the head, the expression and

the occupation of the sitter in almost every case showing distinct individuality. It is fairly easy to produce a number of portraits dissimilar in pose, and so on, but Mr. Lewis does much more than this; his portraits are not only different when compared with each other, but they are like when compared with the sitter. Look, for example, at the portrait of the Right Hon. John Burns, M.P., and notice the way in which the photographer has suggested, by the slightly forward position of the chin, the head slightly on one side, and the squared shoulders, the thoroughly fighting character of the man. In the picture of Cavendish Morton, too, we have that suggestion of the mysterious which is associated with Morton's pictorial expression of himself. Portraits of Nelson Dawson, the well-known artist and enameller, and F. M. Halford, the authority on fly-fishing, gain individuality by the use of what has been called "the attributes"—in the one case the easel and canvas

and in the other the artificial fly which has just been mounted. The kindly gleam of the eye in Prince Kropotkin's portrait—an old favourite this—again shows that Furlley Lewis has no set formula which he follows in his work, but that he is ready to seize the salient features of each and every sitter. Who would think, to look at the portrait of this kindly old man, that he is still regarded by Russia as a most dangerous revolutionary? One would unhesitatingly accept Lewis's version of his character before that of the bureaucracy. For magnificent composition and strong modelling, the portrait of Oscar Arndt stands out almost pre-eminently. There are one or two portraits of ladies, of which we unhesitatingly prefer those of Tina Lerner. Here we realise quite clearly that the photographer has had a graceful, *petite* sitter to deal with, and though it would be more than a miracle if, with such a sitter, the cleverest photographer got more than a shadow of the sitter's charm and personality, we are made to feel something of those characteristics.

One feels inclined to ask on leaving Lewis's display how much of its character, its homogeneity, and its thoroughness, without that stodginess which thoroughness often bears along with it, is due to the "one-man" method of working. When the finished portrait owes its existence, not only to the operator who saw the sitter for ten minutes, but to the developer, the retoucher, the printer, and the trimmer and mounter, how can it show any continuity of effort? The method of Furlley Lewis is to carry the work on throughout himself, and the consequence is that every touch right up to the placing of the print upon its tinted papers and the position of the signature or embossed initials is but one step further in the direction of the preconceived ideal. We could have wished that, instead of using ordinary black ink for titling some of the prints, a fine black-lead pencil had been employed; but one can realise the pressure under which such a show of work is prepared by a busy man, and our readers should feel glad to have an opportunity of seeing so fine an exhibit of Furlley Lewis's work.

In his method of treatment, H. Walter Barnett differs considerably from either Lewis or Crooke. The strong point in his portraiture is the constant evidence of his power to seize the essentially feminine characteristics of his feminine sitters, and to represent them as charming, graceful, refined, and beautiful women. Apart from the point already referred to, the visitor to the gallery will be most interested in the technical methods employed. The red chalk carbons on canvas grain transfer paper, plate-marked, and framed in narrow polished

wood beadings, are very effective, while other carbon print on a pyramid grain transfer paper, also plate-marked, have much of the effect of fine quality photogravures. The coloured work is exceedingly dainty and delicate, and shows how much more effective such tinting is than more full colouring.

William Crooke has somewhat marred the *ensemble* of the south wall by too equal spacing. The work shown is very similar to that seen in previous years, notable on account of its size, its fine quality, and the way in which each picture holds its own, though simply mounted with a cream margin of about a couple of inches and a *passepartout* binding. The large head and shoulders picture of the Earl of Wemyss is particularly fine, and "carries" well. It at once strikes the eye as one enters the room from the doorway opposite. Strength and simplicity are perhaps the keynotes of Crooke's work, and he quite evidently thoroughly understands how to get those qualities in his small original negatives which will tell well when these impressive enlargements are made.

The small display of Mattype must be sought just to the left of the entrance in the North Room. The work is curious, uneven, the coloured portrait of the back of a lady's head being a fine thing, while its companion, a profile of presumably the same sitter, is very commonplace.

Frederick Hollyer again shows a number of his irreproachable platinotype reproductions of various old masters.

The whole of the west wall is occupied with the exhibit of Raines and Co., of Ealing, consisting of prints and enlargements from negatives by Herbert G. Ponting, F.R.G.S. I go without saying that here we have perfect technical work both as regards the original negatives and the contact or enlarged prints. These prints are mounted with precision, and there has been shown considerable taste in the selection of the tinted papers. The framing has been carefully and substantially carried out. Yet the show as a whole irresistibly carries the mind back to the photographic exhibitions of fifteen years ago, and one realises, on comparing this wall with the work in the West Room, how far pictorial photography has advanced during the past few years. This is, of course, no condemnation of the work of either the photographer who produced the negatives or the firm who enlarged them and framed the pictures. The work was not done chiefly from a pictorial point of view. The excellence of this work will no doubt suggest to the professional photographer how varied are the accomplishments of the exhibiting firm.

## THE PROPOSED GALLERY OF PHOTOGRAPHIC PORTRAITS.

Nos. 688 to 789 in the exhibition, arranged on the balcony between the heads of the two staircases, represent a selection of portraits of eminent British subjects recently acquired by the Royal Photographic Society. A considerable number of these are portraits made by Frederick Hollyer, mostly of artists and literary men. To these have been added a large number of Woodbury-type prints, which form a series of "Men of Mark," arranged by Mr. G. C. Whitfield. We learn from a note in the catalogue that it is the intention of the society to index and store all portraits entrusted to it under such conditions that they shall be available for reference.

It would, however, appear advisable for this decision, supposing it to be official, to be revised very considerably, otherwise we can see the Royal Photographic Society pledged to a task of storage and indexing which could only be undertaken by somebody having a commercial interest in such work, such as a press agency or an illustrated newspaper. As we originally understood the scheme, which is now

illustrated in the exhibition, a collection was to be formed of portraits which while being masterpieces of photography were also portraits of persons of undeniable eminence. On these lines the nucleus of a collection might be formed the existence of which would be demonstration of the argument that, in the absence of a painting, good and permanent photograph of a celebrity might appropriately be included in a national collection. The strict letter, however, of such a scheme appears to have been widely departed from, if we may judge from the names which figure in the present collection in which we find persons with very slight title indeed to be regarded as eminent, or even celebrated. While we quite sympathise with the Royal Photographic Society in its request for assistance in this scheme, we would ask that due consideration may be given to the possibility whether donations to such a collection may not be imposing a load on the society which it is unable to bear.

## THE WAYS OF SELECTING COMMITTEES.—SALON AND ROYAL.

VISITORS to the two exhibitions can hardly avoid making a comparison between the representation on the walls of the respective selecting committees. In past years the Salon has balked such comparison by withholding the names of those responsible for the work of selection, or by leaving the visitor

to assume that the whole membership of the Linked Ring acting together or in irregular "shifts," enjoyed equal privilege in the matter of selection. However, this year the names of the selection committee appear on the catalogue—surely now we hope, from any desire on the part of other less close

red Links to disavow responsibility for their acts?—and before the visitor can obtain, at any rate, a glimpse into modern art of Salon-making by the latest methods. The following are the figures:—

SALON.		ROYAL.	
Total number of pictures, 203		Total number of pictures, 309.	
Craig Annan .....	10	W. R. Bland .....	none
Colon Arbuthnot .....	8	E. T. Holding .....	5
Alfred Benington .....	5	Charles F. Inston .....	6
Langdon Coburn .....	21	Furley Lewis .....	3
George Davison .....	none	J. C. S. Mummery .....	2
Robert Demachy .....	7	G. A. Storey .....	none
Frank Eugene .....	10	B. Gay Wilkinson .....	none
Ernst Friedrich Kühn .....	none		
Ernest de Meyer .....	28		
Edward J. Steichen .....	39		
Ernest Stieglitz .....	6		
Frederic H. White .....	10		
Joseph T. Keiley) .....	4		

Total (=72.9 per cent.) 148      Total (=5.2 per cent.) 16

The above figures are obtained by taking the whole of the Salon exhibits (Autochromes as well as prints) and the pictorial section only in the case of the Royal. As the technical committee select Autochromes at the New Gallery, it is impossible

## THE TRADE EXHIBITS.

### Wellington and Ward.

Messrs. Wellington and Ward occupy their accustomed Walton most effective stall on the left of the entrance. Here, as in previous years, they make an excellent exhibition of negatives on the famous Wellington plates, including the new "Extra Speedy Special," together with lantern slides and transparencies on the bromide and light lantern plates. Prints and enlargements on the Wellington slide, S.C.P., and P.O.P. and self-toning papers are also excellently arranged, and include the work of S. E. Fincham and W. L. F. Stell, in addition to that of Mr. Wellington himself, and the visitor may also see specimens of the work of the light-filter now issued by the Wellington orthochromatic plates, as well as examples of the "exposure calculator" recently reviewed in our columns.

### Raines and Co.

The Raines and Co. exhibit occupies the whole of the wall on the left upon entering the South Room. It is divided into seven panels, the background being natural colour canvas with dark oak for the divisions.

The display consists of thirty-four enlargements from negatives by H. G. Ponting, and many of the subjects will be recognised by the visitor who visited the exhibition at the Little Gallery of the "B.J." spring. Where Messrs. Raines' present exhibition differs from the previous is in the diverse treatment of the subjects; the numerous print-processes and varying mounting and framing schemes adopted, are serving to admirably demonstrate the many-sidedness of the photographic service (by the catalogue we are led to understand that the display is arranged with that purpose in view), at the same time give Ponting's superb negatives additional distinction by the evidently fully thought out treatment accorded them. For example, the tiny Japanese damsel who attracted so much attention under the titles, "O Tsuné San" and "A Study by the Shoji," now reappears in two "red chalk carbon enlargements in all the glory of wide-ranging multiple mounts. The price at which these, and other fine carbon enlargements, including four views of the Matterhorn, are marked, viz., 25s. each framed complete, seems so absurdly low when compared with the prices to which one is accustomed at other exhibitions that it would prove of interest if Messrs. Raines would make the usual custom of affixing the red labels denoting the number of copies disposed of.

The taste displayed in the preparation and arrangement of the exhibit should serve to dispel the prejudice still existing in the minds of many against the so-called "trade-work," and much benefit will no doubt accrue to Messrs. Raines and Co. as a result of their enterprise.

### Dallmeyer, Limited.

The Dallmeyer exhibit is much on the lines of previous years, and includes a series of the Stigmatic lenses with examples of work done

to include both these latter and the prints in the above calculation; but it may be added that none of the pictorial selecting committee exhibit work in the Autochrome section.

In regard to the Salon committee, it is understood that the actual work of selection in London was done by those whose names appear in italics. Others, perhaps, of the committee performed similar duties in the countries of their residence. The name of Mr. Keiley, of New York, does not figure in the Salon catalogue, but as he is believed to have taken part in the selection we bracket him with the others.

It may be interesting to add to the above table one or two figures as to the pictures shown by other members of the Linked Ring who for years past have contributed prominently to the exhibition:—

A. H. Blake .....	1	Reginald Craigie .....	1
Will Cadby .....	1	Fredk. H. Evans .....	1
Mrs. Carine Cadby .....	1	Alex. Keighley .....	1

A further numerical example of the altered conditions at the Salon this year is in the fact that, while usually sixty of the seventy members of the Linked Ring are exhibiting, there appear in the present list of "Links" the names of forty who are unrepresented at the present Salon.

In regard to the composition of the pictorial section of the Royal Photographic Society's Exhibition, the total of 309 pictures represents the work of as many as 182 photographers.

with them and with the popular "Adon" cameras made, or recommended, by Messrs. Dallmeyer also figure in the exhibit, and special attention may be directed to the triple-extension model of the "Correspondent's" camera.

### "Sanger-Shepherd and Co.

The customary stall of Messrs. Sanger-Shepherd contains a fine selection of this firm's apparatus for colour photography, the chief item of which perhaps is the quick-change adjustment for plate cameras, serving to give three successive exposures through three filters. These latter are now made to give a ratio of 1:1:1, and the attachment is conveniently made in black Russia leather to match leather-covered reflex and other cameras. Among the examples of

work which are shown are transparencies by the Sanger-Shepherd process by Colonel Lysaght, Mr. Savile Kent, and Mr. Harry Grylls, who shows a coloured photograph of some stained glass windows taken for him for the purpose of preparing a duplicate window. Some excellent examples may be seen of the work of the graduated light-filter, the various forms of which Messrs. Sanger-Shepherd are prominently showing.

### O. Sichel and Co.

The well-known "Sickle" reflex camera and a series of specimens of the lately introduced "Fulmenar" lens occupy a large portion of Messrs. Sichel's space. Some striking examples of rapid work by the lens are shown. We would draw attention to the very convenient "Finsbury" head-rest and screen, recently noticed in these columns. It is an accessory which can really be best appreciated when examined by the photographer. There is a new model of the "Sickle" mercury-vapour lamp, which should also interest professional workers. The outfit is complete with two tubes, which are tilted simultaneously, with one resistance, and the price complete is to be about £16 10s. The outfit may also be fitted with the two resistances, and for this the price is about £20 complete. The prices include two of the K type of lamp, 45 in. long, each with a candle-power of 700, with resistance suitable for burning singly on 100 volt, or two in a series of 200 volt. The firm naturally exhibit a full line of specimens of the work of their "Ideal" P.O.P., C.C., gaslight, and bromide papers.

### C. P. Goerz, Limited.

Striking enlargements of the work done with Goerz cameras and shutters are, as usual, the feature of this firm's exhibit. One most remarkable piece of work is a large flashlight photograph of a

dinner from a negative taken in America. Among the apparatus will be noticed the latest model of the pre-eminent Goerz-Anschutz folding camera, and of the later introduction, the "Tenax" double extension folding camera. These, with specimens of the various mountings in which the Goerz positive and telephoto lenses may be obtained, together with examples of the equally high-class "Sector" and other shutters, complete the collection exhibited by this leading optical firm.

#### W. Watson and Sons, Limited.

A new model of the "Argus" reflex camera is a leading item at Messrs. Watson's stall. The camera is built with a revolving back, a new pattern of finder, and with the cover hinged so that the ground glass is readily accessible for cleaning purposes or for replacing.

The camera front has a continuous rackwork movement actuating the extension which provides for the use of the single combination of the "Holistigmat." The combined finder, level, and telemeter, recently introduced by Messrs. Watson, is also shown, as is also a new tripod stand, which is very light and rigid, and has an ingenious method of fastening which permits of its being very quickly erected and folded up.

We may also mention an improved "process" camera with central screen gear, provided with micrometer stop graduated in millimetres. The dark slides are inserted by a novel method, by which all danger of wedging is obviated and the convenience of the operator increased. It has also an improved rising motion to the front actuated from the rear of the camera, so that the operator can centre his copy without moving from his position.

#### Burroughs Wellcome and Co.

The advantages provided by the many varieties of "tabloid" photographic chemicals are demonstrated in Messrs. Burroughs Wellcome's exhibit by a number of illuminated transparencies among which is an Autochrome slide developed with "Rytol," a selection of negatives and positive transparencies which owe their quality and range of colours to several of the "tabloid" preparations. Tabloid stains and dyes are also illustrated in the same way, and attention may also be directed to the results obtained by the firm's modified method of sepia toning, in which thiostannous is used in place of sodium sulphide.

#### Adams and Co.

The hand-cameras for which Mr. Adams has made his firm famous form a small but most interesting exhibit. The "Videx" camera, which first merits attention, is now made in two models. The "De Luxe," providing triple extension, rack and pinion rising front, pro-

"Videx" De Luxe Model.

vidually controlled slow speeds of the focal-plane shutter, and its adjustable working parts metal working upon metal. The price of this model is more than the previous standard pattern of "Videx," but, on the other hand, the price of the "Popular" model, which is quite as efficient as the previous standard pattern, has been reduced. We hope to refer to these instruments more fully shortly, but

"Videx" Popular Model.

should certainly be seen by those interested in the reflex type camera. The other hand cameras shown are the "Idento," a portable instrument with the valuable feature that the finder does actually show the alteration in picture produced when the front is raised, and the still more portable "Vesta" with its rise of front each of the plate.

### Wratten and Wainwright.

Colour in various forms exudes from the dark corner in which Messrs. Wratten have taken their space. We doubt if the firm's artistic director would admit the verb as descriptive of the phenomenon of colour; nevertheless upon the sides of a case, which resembles in size and shape an overgrown cottage piano, they strive to convey much information in a demonstrative way. In addition to exhibiting by means of Osram lamps, colour-filters for colour work and photo-micrography, and the Wratten filters for colour work, they display examples showing the use of panmatic plates with the Wratten K screen for portrait work and outdoor photography, the latter example being a photograph of "Mauretania," in which the vessel appears curiously small. Perhaps the most interesting part of the exhibit is a transparency giving the renderings of a series of coloured strips on a panmatic plate used behind a six-times screen, on an ortho' plate six-times screen, and also on an ordinary plate. The way in which the ortho' plate fails to render the green strip is quite noted. Messrs. Wratten also invite the visitor to set in motion a wheel containing segments of red and green, the combination of which by the rapid motion produces a sensation of yellow.

### Kodak, Limited.

Perhaps the chief novelty among the many which are shown at the stall of the Kodak Company is the new model of the ingenious "stereograph" reflex camera. The pattern introduced during the present summer was of a fixed focus variety, and while it gave a

size image of the subject, it obviously suffered in comparison with the stereotyped patterns of reflex. This the Kodak Company remedied by introducing a modification in which a focussing movement is provided. The new pattern, complete with rack

ing, R.R. lens, and variable shutter speed, is sold for four shillings. It provides for focussing up to within about 5ft. Another Kodak is the "1A Folding Pocket Kodak Special," which takes a picture 4½ in. by 2½ in., and is provided with a very ingenious automatic focussing lock, by means of which it may be used simply

as a fixed-focus camera, or the fine focussing adjustment instantly brought into use when required. Though differing little in construction from previous Kodaks, it allows of larger lenses being used. The compactness and neatness of the apparatus may be warmly commended. Kodak tanks for the development of plates, films, and film packs naturally occupy a good share of the space, and those contemplating tank development of plates should not omit to see the ingenious device by which each plate is certainly and quickly loaded into the Eastman tank.

### The Platinotype Co.

In regard to this exhibit, we can only repeat the good things which have been said of platinotype prints and platinotype papers in past years. The company are masters of the art of displaying their wares to good advantage, and are equally fortunate in demonstrating the process, as they do each afternoon at 4.30, and on Tuesday, Thursday, and Saturday evenings at 7.30. Among the prints hung in the miniature exhibition behind the demonstration table are some excellent photographs by Histed, and by Goldensky, of Philadelphia. One canvas-effect portrait of a lady should be specially noted, as also the charmingly coloured platinotype by Drummond Young, of Edinburgh.

### Ilford, Limited.

The centre stall of the Fountain Court is this year held by the Ilford Company, who will distribute from it free samples of their plates and papers, together with specimen prints on the various descriptions of the latter. There are also transparencies illustrating the use of the Ilford "Alpha" gaslight and bromide lantern plates, and some excellent stereoscopic transparencies shown by M. Richard from Verascope negatives, for the printing of which the Alpha plates are employed by the French firm. We were also shown some copies of an interesting book just published by Methuen—"The Lore of the Honey Bee," illustrated throughout by the author, Mr. Tickner Edwardes, from negatives on Ilford "Monarch" plates, printed (from originals for reproduction) on the firm's glossy bromide paper.

### Paget Prize Plate Co.

Though not occupying a great space, the exhibit of prints on Paget papers makes a fine display. The panel filled with bromides shows the excellent effects obtained, both with and without toning, in the case of landscape and portrait subjects. The self-toning papers show a very pleasing sepia tone, whilst the Platinoid (platinum-toned) P.O.P. is shown to good effect in the case of a number of portrait negatives. "Gravura" paper is represented by a series of prints of cold tone, very soft and charming in their effects.

### Kodak Printing Papers.

In the North Room there is a separate display of the Kodak papers, including a series of prints on self-toning collodion paper; a fine selection of work, entirely portraiture, on white "Velox"; some of the big exhibition results which are obtainable on Royal bromide, sulphide-toned; and in the fourth and fifth panels some of the more delicate work in landscape and portraiture to be done with Velox, and examples of the work of the Kodak Velvet Solio printing-out paper.

### Ozobrome, Limited.

Mr. Manly's exhibit is not a large one, nor can a wall display give a proper idea of the practical facilities of the Ozobrome process. However, the prints, which are of various subjects, are interesting on account of affording inspection of the excellent colours which characterise Ozobrome tissue. Among the prints can be seen the green-black, marine-blue, sepia and warm sepia, warm black and blue-black, and Italian green transferred to papers of various tint and texture.

### Leto Photo Materials Co

The whole of the end wall in the North Room is filled with a large collection of both amateur and professional photography printed in one or other of the Leto papers. These include the "Seltona" (self-toning), also the recently introduced "Antique" grade, together with "Tintona," which gives excellent tone effects without special

toning, Leto "Platino," specially amenable to platinum toning; and Leto gaslight paper, the varied results of chemical toning of which are shown in a series of excellent examples. The Leto Company also exhibit a collection of professional work produced on their papers.

### The Autotype Co.

The whole of one long wall of the North Room is, as usual, taken by the Autotype Co., who, in addition to exhibiting a number of their well-known reproductions of works of fine art, make a striking and, in some respects, novel display of carbon printing. It will be noticed that a good many of the prints are of quite small size, and are therefore of interest as contraverting the view, which is perhaps held by some amateur photographers, that carbon printing is only for large work. One very interesting picture is a panoramic view of the Alps (from three separate negatives by A. L. Mumm), which are pieced together by the carbon printer in a way which almost entirely baffles detection. Very close examination will show the wavy lines of the joins, but the picture shows that for work of this sort the carbon process may be successfully worked. One or two prints on the Autotype tissues from negatives taken inside and out of the "Mauretania" and "Lusitania," by Bedford Lemère, should

be of popular interest, whilst fine examples of Royal portraits of the Prince and Princess of Wales, are shown from negatives of Langier, of New Bond Street.

Professionals should not miss the examples of a new specialty, the Autotype Company's, called by them "stained drawings," whilst retaining in some respects photographic quality in the process. The examples are the first to be exhibited, although the Autotype Company have been making them for the profession for some time past. (Nos. 30, 31, 32, and 42.)

Naturally, the introduction of Autotype oil-printing tissue should be represented in the exhibit, and one or two examples of work upon it by Mr. John H. Gear and Mr. Bertram Park fully endow the good things that have been said of the tissue, which, as well pointed out in the past numbers of the "B.J.," possesses great strength and toughness under the pigmenting brush.

### Sciopticon Lantern Plates.

A large number of slides by the Woodbury process in various colours are again shown, and demonstrate the excellent brilliancy results obtainable by this now little-used process.

### THE PROGRAMME OF

THIS year, as already announced, the New Gallery is to be opened every evening of the week, and the visitor who pays his shilling at the turnstile will not only have the right to inspect the various photographic collections but, on whatever evening he makes his visit, will be able to hear a lecture, in almost every instance by someone who has made a subject or a district his special photographic study. The following is the full list of the lectures, which commence each evening at 8 o'clock:—

- Saturday, September 19.—"Protective Devices in Nature." By W. Farren.  
 Monday, September 21.—Autochrome lecture, "The Thames from Cirencester to Maidenhead." By J. McIntosh.  
 Tuesday, September 22.—"The Romance of London Streets." By A. H. Blake.  
 Wednesday, September 23.—Autochrome lecture, "The Thames from Windsor to Richmond." By J. McIntosh.  
 Thursday, September 24.—"The Path of the Eagles: Elba as it was and is." By Rev. T. T. Norgate, F.R.C.S.  
 Friday, September 25.—Autochrome lecture, "The Thames from Kew Gardens to the Sea." By J. McIntosh.  
 Saturday, September 26.—"Afar in the Fatherland." By W. L. F. Wastell, F.R.P.S.  
 Monday, September 28.—Autochrome lecture, "The Thames from Cirencester to Maidenhead." By J. McIntosh.  
 Tuesday, September 29.—"Wanderings in Zooland with Note-Book and Camera." By F. Martin-Duncan, F.R.P.S.  
 Wednesday, September 30.—Autochrome lecture, "The Thames from Windsor to Richmond." By J. McIntosh.  
 Thursday, October 1.—"Savage Architecture in British New Guinea." By A. H. Dunning, F.R.C.S., F.R.P.S.  
 Friday, October 2.—Autochrome lecture, "The Thames from Kew Gardens to the Sea." By J. McIntosh.  
 Saturday, October 3.—"Some Glimpses of the Green Isle and its People." By C. H. Oakden, F.R.P.S.

**THE PLATINOTYPE ANNUAL OUTING.**—On Wednesday in last week the annual excursion of the employees and staff of the Platinotype Company was held. Eastbourne had been fixed as the destination of the party, and the early hours of the morning saw a company numbering only one or two short of a hundred embarking by train from Penge. The arrangements for the day had already been made by Mr. W. H. Smith, the manager of the Platinotype Works. Mr. W. Willis and his brother, Mr. John Willis, arrived by motor, and the whole party breakfasted at the Grand Hotel, their headquarters for the day. The morning was spent in an excursion to Pevensey Castle, and one o'clock saw the whole company assembled at luncheon, when Mr. W. Willis welcomed his guests, Mr. P. R. Salmon, Mr. S. H. Wratten, and Mr. George E. Brown. It is characteristic of the friendly reception accorded to visitors by Mr. Willis and his colleagues that their health should be drunk by the company. Mr. G. E. Brown, in briefly responding, referred to the admirable relations existing between the employees and staff of the company, and to the

### EVENING LECTURES.

- Monday, October 5.—Autochrome lecture, "The Thames from Cirencester to Maidenhead." By J. McIntosh.  
 Tuesday, October 6.—"Wild Birds and their Ways." By Bickerton, F.Z.S.  
 Wednesday, October 7.—Autochrome lecture, "The Thames from Windsor to Richmond." By J. McIntosh.  
 Thursday, October 8.—"The Gorges of the River Ardèche." By G. E. Thompson.  
 Friday, October 9.—Autochrome lecture, "The Thames from Kew Gardens to the Sea." By J. McIntosh.  
 Saturday, October 10.—"Southwell Minster." By E. W. H. Piper, Hon. M.S.A.  
 Monday, October 12.—Autochrome lecture, "The Thames from Cirencester to Maidenhead." By J. McIntosh.  
 Tuesday, October 13.—"A British Touring Ground." By A. Marshall, A.R.I.B.A., F.R.P.S.  
 Wednesday, October 14.—Autochrome lecture, "The Thames from Windsor to Richmond." By J. McIntosh.  
 Thursday, October 15.—"Picturesque India." By Ernest R. Atkinson.  
 Friday, October 16.—Autochrome lecture, "The Thames from Kew Gardens to the Sea." By J. McIntosh.  
 Saturday, October 17.—"Some English and French Gothic Churches." By Henry W. Bennett, F.R.P.S.  
 Monday, October 19.—Autochrome lecture, "The Thames from Cirencester to Maidenhead." By J. McIntosh.  
 Tuesday, October 20.—"Flower Photography." By E. Seymour.  
 Wednesday, October 21.—Autochrome lecture, "The Thames from Windsor to Richmond." By J. McIntosh.  
 Thursday, October 22.—"Life and Work on the Panama Canal, 1908." By Vaughan Cornish, D.Sc., F.R.C.S.  
 Friday, October 23.—Autochrome lecture, "The Thames from Kew Gardens to the Sea." By J. McIntosh.  
 Saturday, October 24.—"The Camera and the Sea." By J. Mortimer, F.R.P.S.

proud position occupied by the firm as the manufacturers of the product unexcelled throughout the world. Mr. Wratten simply expressed his satisfaction at being present. Mr. W. H. Smith, calling upon the company to express their thanks to Mr. Willis for the entertainment of the day, instanced as an example of the feeling existing in the firm that the terms of service of those who are sent, if added up, would represent a period of 1,000 years. Mr. Willis appeared almost to deduce from this fact that the manufacture of platinotype paper dated back to somewhere near the Norman Conquest. Mr. Willis briefly replied, expressing the pleasure it gave him to be among them. Under the leadership of Messrs. Smith and E. A. Salt, a most enjoyable afternoon was spent, and when tea, the time came to take the train for London (and particularly when a solitary, but happy, journalist detained at Cannon Street it was felt that one of the most pleasurable festivities of the year had passed, and that fortunate are they who may look forward to the hospitality of the Platinotype Company another year.

## THE PHOTOGRAPHIC SALON.

The gallery of the Royal Water-Colour Society at 5A, Pall Mall East presents an agreeable aspect as furnished by the "members of the Linked Ring who conduct the Photographic Salon," and if one could stroll round with a cursory glance and be out again in ten minutes one might be disposed to call the exhibition a distinctly interesting show of unhackneyed things. But the critic who has to creep round and come again and again before the same works loses a good deal of that pleasurable impression. There is a style of work that does not pay for scrutiny or logical thought or critical analysis, but begs a sort of happy-go-lucky indulgence from minds more emotional than philosophical, and this is the sort that finds its way largely to the Salon. There are scarcely three works here that satisfy intellectually as well as emotionally. One has to forgo much—very much—for the sake of "feeling" and "mood," or the frantic strivings after those qualities. In these days men build reputations on those weak and shiftier soils. It is the way of the worldly, and to resist it would be the vainest of struggles. The critic must bottle his notions and try to get at the picture maker's point of view, if there is one, lamenting, in his heart, that so many people of culture should interest themselves in the mere top froth of the artistic deeps.

As the gallery is very conveniently divided into groups of work by the different exhibitors it will be easy to treat the show strictly in the order of the catalogue. We may say that this method of hanging is highly advantageous, and we congratulate the hangers upon having adopted so sensible a course. Nos. 1 to 8 are by Malcolm Arbuthnot. The first is called "The Pool." It really shows part of a horse, which may be supposed to be drinking at a pool, if not cropping grass. The semi-animal merely shows to what lengths Mr. Arbuthnot can carry his old trick of flat silhouette without being able to tell when it becomes stale and unprofitable also. By far the best of the group is "The Beach" (2). This, being fortunately in quite the opposite method, is distinctly a charming view of a seashore from a high point of view, and having a nice arrangement of figures dotted about near the top of the picture. "The Labourer" (3) and "The Topsail Yard" (4) are cheerless things, the first ill-judged in its trite composition, and the next having none of any sort. The clouds in "The Hillside" (6) are unnatural, and the figures reach the lowest depths of the commonplace. There is a feeling of atmosphere in "The River" (7), but to our unlucky eyes the bald-looking ribbon that fills up the distance might more easily be a road. Visitors on the look-out for the "new point of view" will find the very thing in "The Bathers" (8), where two tiny distant heads rising out of the water are seen through the spokes of a near and consequently huge wheel of a bathing machine, which is out of focus, and a flat silhouette, as usual.

### Demachy.

The oil prints by Robert Demachy which come next show that finer feeling which relies upon the more approved traditions of art and does not seek a bubble reputation at the camera's mouth, if we may so express the photographic process known as "selection." These prints have each an honest and sincere impulse towards the securing of artistic qualities. They are beautifully rich in colour, neither rusty nor varnished, and the portraits show remarkable skill in the most difficult of all branches of work when a method of control is adopted. We believe that M. Demachy has made a better show on previous occasions, but all who have attempted oil printing in portraiture will acknowledge the cleverness of "Portrait of Mlle. G. M." (9) and "Portrait of Mlle. B." (11), the latter most luscious in the quality of the black costume. In "A Head" (15) the expression is a little mournful, but the "Portrait of M. C. D." (16) is certainly the finest portrait in oil printing we have ever seen. Here the expression is animated and the face well modelled. It is entirely free from a peculiarity of M. Demachy's work—namely, the over-accentuation of the dark markings that sometimes occur in his faces, however they are lit. This is observable in No. 9, and also in "Blanche" (18). A nice subject of girls in white dresses who frolic amongst majestic poplars, combines a worldly gaiety with the dignity of nature quite in the manner of French art traditions.

### Lagarde, Emanuel, Molesworth.

"A Young Girl" (10), by Céline Lagarde, is rather too obviously composed to be quite comfortable; her "Road to the Cemetery" (12)

is pleasing, in spite of its title. "Curiosity" (14) is C. H. L. Emanuel's only little gem here this year. It shows some little children crowding round a doorway. It has not quite the smallness of scale that we are accustomed to from its maker. Bagot Molesworth, M.A., sends "Pompeii" (19), an excellent subject of the Temple of Apollo, and possessing considerable quality, some of which is no doubt obtained at the expense of true tonal values.

### De Meyer.

It is not incumbent upon us to dwell at very great length upon the works of the Baron de Meyer, fine as they are, since most, if not all, have already been reviewed by us when dealing with a previous exhibition in London. In view of that fact and of a rule which forbids the hanging of works previously exhibited in London, we are rather surprised to find them here at all. To our minds the "Portrait of the Painter Favai" (21) is by far the best, and of the still-life groups we prefer "After Lunch" (24). The "Baroness de Meyer" (27) suffers from a hard dividing edge between the bright tone on the bust and the low tone of the sitter's right arm. There are eight examples in all.

### Benington.

Five works by Walter Benington are a disproportionate display compared with the single works shown by other Links of more firmly established reputation, or to the absence of works by others whom we know to have submitted work not below their usual standard. Moreover, we cannot honestly say that we think Mr. Benington is striding rapidly towards a high position among pictorial photographers. His prints are uniformly dark and unpleasantly granular, and his subjects too often follow the latest craze of camera workers for taking at close quarters some wretched object of no intrinsic beauty—a thing which can only be beautiful under certain conditions of light and colour which usually manage to elude the photographer. This criticism applies more or less to "The Bridge" (28), "On the Top of the Hill" (29), "Night" (31), which is intended to represent moonlight, but does not, and "After the Storm" (32). The landscape subject, "The Rainbow" (30), is much more pleasant in subject, but how Mr. Benington can think that this murky picture suggests to the mind the glorious effect of a rainbow, with the conditions of purified air and bright sunshine that should go with it, we are quite at a loss to know. The low passage of light in the sky appears to be rather too bright for the rest.

### Coburn.

It is a real joy to see that, in his monochromes at least, Mr. Coburn is developing a finer sense of subject than he displayed a year or two back when the girder obsession was heavy upon him. Even the sham and trumpery pavilion at Brighton is made to look imposing. But heaven help the publisher that should be persuaded, against his judgment, to use such a subject as an "Illustration for the 'Arabian Nights.'"! As well illustrate "Odyssey" by photographs of the classically derived buildings in "The White City," "The Court of Honour" (34) has good colour and quality, except where the domes and pinnacles disintegrate into the air. "Saltwood Castle" (35) is hard and black. We wonder that Mr. Coburn should have thought his original under-exposed plate worth enlarging. "Rainy Evening at the Franco-British Exhibition" (36) is one of the best of its series, and gives well the melancholy of that pleasure resort when bodily comfort deserts it, and electric arc lights flaunt their icy beams where the mellow daylight lingered. But the best of all is "Fireworks" (40), highly effective in its bright splashes of light from rockets, and the illuminated towers in the middle distance. These towers, dimly lit without and brightly within, are beautifully tender in their tones. We are not quite satisfied about the colour of the print. We think "The Flip Flap" (42) ugly in every respect, and the vamped-up clouds behind it increase our disappointment. There are two views of St. Paul's, widely different in treatment, but interesting if only upon that account. "No. III." (37) shows the edifice as seen from a housetop or window at Ludgate or thereabouts. Steam from a train in the foreground does much for the subject pictorially. It is a dignified view, and, considering the hundreds of times the same aspect of the cathedral has been photographed, Mr. Coburn's may be said to escape a charge of being hackneyed. We could have wished more life and movement, more flicker and variety

in the street, which now is dull and monotonous in tone, near and far alike, and more befitting a city of the dead. In "No. IV." (38) the general effect is brighter, because of the bridge and water over which the fane towers. But here another sort of monotony occurs. A stodgy, sticky uniformity of tone smothers detail and stands in the way of aerial perspective. The others of Mr. Coburn's ten examples call for no special remark.

#### A Batch of Single Examples.

Next we deal with Mrs. Keene's "Der Bauer" (44). He is an excellent type, and sits with pipe and beer in truly characteristic manner. His wrinkled old face is a fine study. Mrs. Coburn's "Portrait of My Son" (46) does not exhibit him in a dignified aspect exactly, and he looks rather over-weighted at the hands and head. "Le Moyen Age" (47) is undoubtedly the finest photograph as such in the show. We would willingly have forgone many of the works of men so much over-represented here this year if we could have had instead more of the solid merit that the works of Fredk. H. Evans never fall short of. In this case he gives us not only perfect photography, but a delightful romantic mood in his picture of a hoary old French castle, the architectural features of which are a pictorial theme in themselves. The sunshine that plays across the front of the building is in every way admirable. "The Medallion" (48), by A. H. Blake, represents another architectural motive, for the medallion is a sculptured circular relief of life-sized Cupids, upon the head of one of which a little girl rests her hand as she gazes at the stone babies. The animate and inanimate are prettily apposite. Mrs. Cadby has been allowed to show a three-quarter length figure portrait of "Mrs. R. C. Thomas" (49). We much prefer it to her bits of grass and so forth. Mr. Will Cadby's "Camilla" (50) is another of his little children in faint tones. She is very charmingly seated upon a stool. "The Swing" (51), by Dr. A. R. F. Evershed, is a snapshot of 'Arrys in a boat swing. It has nice lines, but one cannot call it choice in subject.

#### Johnstone, Mrs. Brigman, Miss Bland, Keiley.

J. Dudley Johnstone's "Snow in the City" (43) is now such an old favourite that we are surprised to find it here. We have admired and described it before. We need only say that the high-lights appear to us too mechanically similar, as though they had all been "breaded out" with the same touch, regardless of textures and distances. His other work we think a much finer thing in every way. In the foreground is a fountain in dark tone, and beyond certain municipal buildings stretch away into the misty distance with excellent effect. The design and composition of this could not be better, and the whole thing is quite harmoniously classic in feeling, in spite of its being "In a Northern City" (45). Three nondescripts, bearing the title "Cock Fighting" (53, 54, and 55), by Miss Bland, do not interest us. Mrs. Brigman uses the nude figure in an outdoor setting, but in such a nebulous and shamefaced sort of way that her allegories are elusive to our understanding. "The Brook" (52) displays a lady undressed and squatting in a trout stream, but if she is there for any pictorial reason at all she should have been treated with more frankness and decision; she is too big to be merely an accessory to the brook. "The Thaw" (56) is another case of a model used under painful conditions, we should think, and for what literary or artistic reason we cannot tell. American pictorialists seem to think that the mere photographing of a nude person gives their work the indisputable cachet of high art. The nicest thing of J. T. Keiley's is the "Study in Grey" (58), which is a good portrait of a man. "The Man in Armour" (57) does not call for remark. Neither does "The Spanish Dancer" (59), though both are nice. It is difficult to see that these little things are of so much artistic value as to be sent across the Atlantic that a London public may admire. As for "The Spirit of Flame" (60), with its awful dabs of white in the eyes, we withhold remark.

#### Eugene.

The ten works by Frank Eugene vary considerably in merit. The portrait of "Prof. Emanuel von Seidl" (61) and "Prof. Rudolf von Leitz" (69) are fine in most ways, though the first is distinctly heavier in tone than it need have been, and the latter is over full of fussy accessories, which rob the face of its due importance. "Music" (62) is a pre-Raphaelite sort of lady playing with a violin; "A Profile" (67) is more in a Pompadour style; "Rebeckah" (63) is utterly satisfying. A charming model has been photographed in a beautiful pose and in a tasteful manner, with a tapestry background

of delightful quality. "H.R.H. Prince Luitpold of Bavaria" (64) is a child seated upon a chair. When we say that his socks are dead white and his shoes dead black our readers will understand how much technicalities count for at the Salon. "Minuette" (65) has certain nice qualities; but why it should be so called and represent a lady at back view sitting on the ground, to all appearance, Mr. Eugene best knows. "Girl with Flowers" (68) is good in arrangement; "Man in Armour" (70) shows too much hand at the bottom of the print, otherwise it is good.

#### Steichen.

Another group of ten represents Mr. Steichen. Something has happened to his "Portrait, Miss Watson" (71), which is all gone away to nothing, and is without any natural strength in the shadows. The lady has also been made to look disagreeable. "Jean Van Biesbrock" (73) is a gentleman who is posed as though he were avoiding a draught in the ear as he cowers below a piece of sculpture that would have made a better picture without his presence. Mr. Steichen has developed an unpleasant trick of making strong accents of black and white, which often come upon some unimportant part of his pictures. In the portraits, "Mrs. Dr. Williams" (74) and "Mrs. Algernon Keene Boyeson" (77), this fault plays havoc with the faces. In "At the Steeplechase" (79) and "After the Grand Prix" (80), the same high-lights, which are further inharmonious by their being of an utterly different colour to the rest of the print, give a most disquieting and unnatural effect. A man's coat and head may be black, but his collar is rubbed or faked some how into a pure white. The bright light that is forced up upon the figures is allowed to be entirely wanting in other places where it would also fall of necessity, as on the ground, for example, which is represented as dark, though a foot touching it is bright with light. These anomalies are unpardonable on any score in open daylight subjects. The limelight sort of effect of this forcing is not only untrue, but unlovely also. It is less objectionable in "Portrait, Lady Ian Hamilton" (75), where it gives a sort of "ghost of the tapestry-chamber" effect. It is seen likewise in "Venice" (72), and in "Nocturne Versailles" (76), where, however, there are other charms of subject and mood which impel us to forgive the vulgarity of the forced effect for once.

#### Stieglitz and White.

These two gentlemen have worked together to produce six pictures in collaboration. Four of them have no title, and are simply numbered. The first, "No Title, No. 2" (81), is a nicely posed lady in a partially clothed state, sitting on something low in a darkened chamber, and holding the handle of a door as she looks round apprehensively. It is the nicest of the nameless series. The next best is "No. 4" (85), where all is lost in murk but a nice face prettily lit. "The Torso" (83) is, as its name implies, a half-length female nude. It has much agreeable quality of tone, but is not effectively lit. Two more nudes flank a central mournful figure crouching over the inevitable globe—the American photographer short cut to allegory. What does it mean? What reference has to the rather hard and edgy nudes on either side, and what are they there for? We should not ask if we could find in this ambitious attempt any art of the sort that exists for its own sake, apart from subject matter.

#### White.

It is a fact that no American or German exhibitor at the Salon has permitted himself to show more than ten examples in monochrome! In Autochrome it is otherwise. Clarence H. White is one of the favoured ones who have reached the full complement of prints as well as the extra six in collaboration; but as his work is quite well known, having been before the public for many years, and as, further, his favourite model, better known still, figures here in good deal, we shall not dwell at very great length upon his group. The best of all, we think, is "The Arbour" (87), which presents a lady standing under trees in a garden or orchard—it is scarcely an arbour. Her head is in shadow, and a faint sort of sunlight falls very prettily upon the lower part of her skirt. "Portrait, Mrs. Schubart" (88), is also well worthy of note. It is a back view, and is in good style. Nos. 90 and 94 are called "The Fountain, Morning" and "Evening" respectively. The title rôle is supported by a little garden pool about the size of a large tea-tray, and having a single jet in the middle. In this a boy contemplates floating a toy boat, in the morning; and in the evening Mr. White's model kneels beside the pool.

ious scrutiny. The latter is the better picture, but neither are remarkable, the former being distinctly below what any intelligent amateur might be expected to produce. "The Young Calf" merges from a nebulous gloom after patient watching, and might all have stayed in obscurity for all the pleasure he gives when he arrives. "Head of a Girl" (96) is very pleasing, however. "The Boy" (92) is another example of the Transatlantic craze to which we have already alluded. Why is this undressed boy posing against rocks? What is the good of such things, except to impress a simple world with notions of the intensity of the art that lies in White's photography? We pass in silence the two landscapes in this gentleman.

#### Dührkoop, Anderson, Schütze, Mortimer.

A Dührkoop there is generally a combination of the qualities that exist singly in the works of others. "Study" (97) has quite a lot of points. It is, in the first place, charming in subject; secondly, is a very fine and simple style, resembling the grand manner of old master; next, it is strong and rich in tone and colour, and without any mere adventitious blackness; the face is beautifully modelled, and gradation could scarcely be more tender; all its force is gained by fair means, and harmony is nowhere violated; it is planned, fills the paper faultlessly, and is in every way a beautiful thing, besides being first-rate photography. All but a few of qualities exist also in the "Portrait of Richard Dehmel" (99) "The Sisters" (103). John H. Anderson's "Steam Trawlers off South" (98) is in such a crinkly state, and, for a print in that condition, so unfortunately hung that we are unable to form any just estimate as to its charms. His "Street in Rouen" (102) is presumably a print. It is rather overloaded and generally grubby. We cannot think that Sidney Carter has been fair to "Kipling" (100), whom it certainly has not flattered. We ask ourselves whether this portrait has been here if it had been of somebody less in the public than Kipling. Mrs. Eva Watson Schütze shows a pretty little scene upon a window seat as "Portrait of Anna-Lisa" (101). F. J. Mortimer, one of the newest of "Links," has been fortunate in having three excellent bromoids hung where the works of so many old masters have been ousted. His best is perhaps "Peace" (107), a fine arrangement of Dutch boats and their reflections. In "The Mill" (105) there is more of reflection than of mill, a rather over-photographic trick; but we have no quarrel with Mr. Mortimer at all score, since he has justified his selection so completely. The mill figures in the landscape called "In Arcady" (106). This it is in the middle distance, and seen through the branches of a tree. We do not care so much for the composition in this plate, but we should like to add that Mr. Mortimer handles the oil process more tastefully than many workers we can call to mind.

#### Craig Annan.

Next come to a group of five by J. Craig Annan, and are first noted by their harmonious appearance. Mr. Annan has a fine taste in painting. "Sunshine and Flowers" (108) is somewhat too flecked for perfect enjoyment, and we think that in simple portraiture a gifted worker shows to better advantage. His "Lady with a Fan" (114) combines just enough of a pictorial element to make interesting for other things besides a pretty likeness of the sitter.

Very Rev. Donald Macleod, D.D." (109), "A. N. Paterson, M.A., A.R.I.B.A." (110), and "Mrs. Grosvenor Thomas and Sister" (111) are three excellent examples of high-class portraiture in the professional stamp. More charm lurks perhaps in the profile and long slender neck of "The Lady Margaret" "Elsa and Rona" (113) is a prettily arranged portrait of two and "George Davison, Esq." (115), is powerful and fresh in

#### Some More Single Specimens.

Mr. Keene's second contribution comes next. She should feel in getting down on these hole-and-corner walls. Her "Plough" (116) is not quite so happy as "Der Bauer." The print is a little hot, and the high-lights are somewhat exclusively centred upon the right to the left. E. Warner's "Navvies" (117) suffers from an excessive retouching of high-lights in a medium that does not tolerate plate. "The Fantastic Pine" (120) is by Harold Jacob. We should have liked it to have more effective chiaroscuro. Reginald is never a prolific exhibitor, so we must not attribute the lack of his having a single picture here to his not being before his

time at the tryst when the hanging was performed. Nevertheless, this fine example should increase his reputation. It is called "After-glow in London" (124), and is at once delicate and strong and highly pictorial. Eustace Calland's "Harvesting" is a vignettied print with parts of much charm—the loaded cart, for example; but there is a general down-hill-look that is more attributable, we fancy, to mounting askew than to the "lie of the land" in the view. The clouds are too much like the accidental forms of free and easy local development of platinotype. Another staunch Link who is cut off with one print is Alex. Keighley. It is "Beech Sprays" (131), and we wonder why it was the chosen picture. "Diabolo" (132), by Ernest G. Boon, is extremely charming, showing a full-length front view of a young girl with bright sunshine behind her, tossing the toy into the air. Full of grace and with abundance of light and air, it should rank as one of Mr. Boon's perfect successes. We cannot say as much for E. Warner's "The Dolphin Inn" (133), a sort of oil in colours arranged with tones utterly false, full of sun-made shadows but devoid of sunshine. The background of A. R. F. Evershed's vigorous workman at half length, called "The Return from Labour" (134), is not sufficiently retiring from the figure. Another attempt at colour is "Cedars in the After-glow" (135), by B. F. Haywood Shreve. It cannot be said to be dead true to nature, but it certainly has a charm of opalescent colour, and is delightful in its way.

#### Cochrane.

Four pictures by Archibald Cochrane prove him to be in good repute with the wire-pullers at the Salon. They make no strong appeal to us, however. "The Builder" (123) is presumably a joke. The names of the others are "Havoc" (125), "Horses Drinking" (127), and "The Lost Piece of Silver" (129).

#### Hofmeister and Müller.

It only remains to speak of a few multi-colour gum prints by the brothers Hofmeister and by Müller. The latter's "Schwerin Lake" (104) is a fine large print, and is highly decorative, as all work of this class is, and must be. We dare not allow ourselves to judge it by the standard of nature without courting disappointment, but the approximation to natural colour in large fields of flat tint is certainly capable of artistic effect in the hands of such clever men as these gentlemen of Hamburg. Nevertheless, we think that breadth degenerates into emptiness in the foreground rushes of the Schwerin Lake. In Herr Müller's "Elegie" (119) the subject is much better fitted to the limitations of the method, hence the impressiveness of the theme is not discounted. The stencilling look comes again, however, with "In the Hartz Mountains" (137), an appearance that is quite in place in works of a distinctively decorative cast. What applies to the works of Müller is equally applicable to those of Th. and Oscar Hofmeister. "Landscape near Rothenburg" (118) is somewhat more dull in colour than it need have been, but its subject has the fine expansiveness that characterises all this class of work. "The Old Mill" (128) is interesting, but "Near Dachau" (136) suffers a good deal by the chilliness of its colour-scheme, especially in the greens, which are what is known as "rank."

#### Autochromes.

The show of transparencies is a very great feature of this year's Salon; we can only lament that it is not more equally representative of the members. J. Craig Annan's "Blue Gown" (138) would be one of the best portraits we have seen in this method were it not that the sitter's movement has hopelessly spoiled the face. The colours of the dress are firm local colours of good quality. With the Autochromes of A. Langdon Coburn one feels that something has often gone just a little wrong. There is no sense of perfect mastery as there is with Baron de Meyer's still-life studies. The "Portrait of G. Bernard Shaw" (140) (how this man's face dogs us wherever we turn!) looks as though the sitter had just emerged from a bath hotter than he could stand. There are eleven in this group, and those that strike us as most successful are the snap-shot "Bavarian Landscape" (142), "Portrait of Lady Ebury" (145), in a garden—a plate that pleases us highly, both for subject and colour—"Still-Life" (147), and "Self-Portrait" (150). The inordinate number of plates by Baron de Meyer says much for his enthusiasm and enterprise, but not much for his forbearance. They are all good, we admit, and we grant him taste and skill, as well as an inexhaustible resource in the way

of setting-up still-life studies of fruit and flowers; but surely twenty examples are much more than enough when all are so similar. The bloom upon "Grapes and Peaches" (162) is happily caught. In "Pink Roses" (164) we are not charmed by the cast of purple over all. A certain looseness of focus seems to have given the Baron a great advantage, and we are convinced that the larger scale upon which he works is the best help to breadth and naturalness of effect. But his score sinks into absolute modesty compared with Edward J. Steichen's twenty-nine. We have more blue globes and green globes, and blue hours and Nocturnes, and all the rest of the catch-penny high art jargon—lead soles to make the art go down. We do not know why the "Lamplight" (173) should also be called "The Blue Hour," since there seems to be none of the blue that comes by contrast out of the windows when the lamps are lit. "Portrait—Mrs. S." (175), is a good example, one of the best, in fact, though "Red Nasturtiums" (182) and "Red Geraniums" (183) are also nice schemes. "Studio Arrangement" (185) shows Mrs. Steichen seated

in a sort of marine store or old curiosity shop. The most pleasing colour of all is perhaps in "The Black Shawl" (186). It is so and rich, and the face becomes a luscious spot of colour, really by the breadth of the beautiful black garment. "Sunlight—M. and Baby Mary" (189) (these domestic scraps of information doubtless another kind of lead sole), shows a lady with disordered robes feeding an infant in nature's way. It boasts of a delicate sunshine effect. The faces of "Mr. and Mrs. Patrick Bruce" are unpleasantly hot in colour. Something good should have of "Towards the Sunset—the Wheat Field" (197)—a lady and gentleman walking through the wheat—a splendid open-air subject, of fine possibilities; but, alas! it misses the mark. In "Man with Palette—Spectral Colours" (198) the spectral colours appeal us. Warburg exhibits three Autochromes, which are very good straight sort of way, but are completely swamped by the "arrangements" and "globes" and other sports of the wholesale German and American contingents.

### THE LAY PRESS ON THE SALON.

The "Daily Telegraph" says:—"These essays in colour do not in any way advance the claims of photography to be reckoned among the fine arts for the purpose of picture making, although many of them are passably interesting as convenient colour notes which require liberal correction before they can be accepted either as realistic or impressionistic records. . . . The prints upon the walls are for the most part of a depressing and uninteresting character. In many instances the first impression they convey is that the maker has been concerned to produce a startling rather than a pleasing or interesting result, and that truth of tone—undeniably the first essential basis of all true pictorial effect—has been lost sight of."

A "Times" contributor writes:—"The selection this year has been carried out by a very small committee of most advanced views, and has been most rigorous. The result is the almost complete disappearance of the more orthodox and humdrum photography, and a Salon which is more like the Salon of a dozen years ago in its relative freshness and modernity than any that we have seen of late years. The Linked Ring, like all elderly bodies, had been settling down into somnolence and respectability. The work which it had admitted was the work which the Royal Photographic Society would itself have been glad to accept, and the justification for a second exhibition contemporaneous with the first was fast disappearing. The departure which has been made this year ought to change the state of things, and, if the organisation is able to stand the strain which such drastic action on the part of a few puts upon it, should revivify a body which was very much in need of something of the sort. . . . The Photographic Salon of 1908 is more fully representative of the most modern side of photography than these exhibitions have been in the past; and if it will promote thought and arouse discussion, . . . pictorial photography at large can only benefit by the process."

The "Daily Graphic," after naively remarking of the Autochromes that are "exhibited under conditions of lighting which render them transparent," proceeds:—"For the part of the exhibition devoted to monochrome photography there is a great deal on both sides to be said. Many photographers are still beaten by the problem of the effort to correct the false relative tones of a subject often less exaggeration and to a kind of spurious impressionism. A good deal of ingenuity is displayed none the less, but it is ingenuity of a kind that may lead to entirely erroneous notions of what the photographer should seek in his art. M. Eduard J. Steichen's "At the St. Chase" displays an extraordinary contrast of light and shade, and seems to suggest too much effort, and, consequently, a tinge of vulgarity. His work on the whole, however, is some of the best exhibited, including some superb specimens in the best taste showing the most correct technique."

The "Morning Post" writes: "As regards monochrome prints the present collection is notable in that it represents the choice of what may be termed the advanced wing of the society, which happens to consist mainly of American 'Links.' It results that the exhibition is far more harmonious in its expression of how the lost type of photographic pictorialism should make its appeal, and it naturally follows that many of the prints will be beyond the comprehension of the average visitor. A yet further result of this concord of opinion is that the Selection Committee have found it almost impossible to put full effect to their ideas as to the lines on which pictorial photography should advance except by hanging their own photographs. It is therefore quite natural that we find, in round numbers, that, while eleven members of the Selection Committee between them show about a hundred and forty prints, the rest of the world has to remain content with but sixty."

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### SATURDAY, SEPTEMBER 19.

Chelsea and District Photographic Society. Excursion to Golders' Green.  
Manchester Amateur Photographic Society. Excursion to Mere Clough.  
South London Photographic Society. Leigh and Benfleet. W. L. White.

#### MONDAY, SEPTEMBER 21.

South London Photographic Society. Tour in Holland. Stanley Fincham.  
Southampton Camera Club. Photography as an Educational Force. F. G. Ryder.

#### TUESDAY, SEPTEMBER 22.

Blackburn and District Camera Club. Fishermen versus Photographers. J. P. Howe.  
Manchester Amateur Photographic Society. Discussion on Mr. J. D. Berwick's "One-Man" Show.

#### WEDNESDAY, SEPTEMBER 23.

North Middlesex Photographic Society. Landscape in Painting and Photography. Horace Mummery.  
South Suburban Photographic Society. Committee meeting.

#### THURSDAY, SEPTEMBER 24.

London and Provincial Photographic Association. The Printing, Developing, and Toning of Velox. W. F. Slater.  
Liverpool Amateur Photographic Association. "Gorges of the River Auldèche." George E. Thompson.  
North-West London Photographic Society. Mounting Methods.

## News and Notes.

OWING to the space occupied by the reviews of the Salon Royal exhibitions a number of articles, paragraphs and customary features of the "Journal" are unavoidably held over until next week's issue.

**SUICIDE OF A PHOTOGRAPHIC MANAGER.**—The dead body of C. Rudd, aged fifty-nine, of Dobie Street, Barnsley, a photographic manager in the employ of Messrs. A. and G. Taylor, of Ship Road, Barnsley, was last week found in the studio belonging to the firm. Near the body was a bottle which contained a quantity of carbolic acid.

"LOOK PLEASANT?" echoed the sitter to the photographer's "My dear man, I simply can't afford to look pleasant. I'm legged, and I'm trying to hold my knees together. When I forget all about my knees, and when I pay attention to my knees, I forget to smile."—*The Globe.*

THE HALIFAX PHOTOGRAPHIC COMPANY advise us that they have been awarded the first bronze medal and highest honours for excellence of "Lilywhite" papers and postcards and "Swiftex," "cex," and "Tradex" plates at the Royal Cornwall Exhibition at Canborne, Sept. 8 to 15. Forty of the competitive prints were "Lilywhite" papers, and two of these received silver medals.

## SUMMARY.

exhibition of photographs in colour by the Brothers Hofmeister H. W. Müller will open at the "British Journal" on Monday September 28, and remain open from 10.30 to 4.30 daily (Sundays, 10.30 to 12.30) until October 24.

Autochromes to be seen in the North Room at the R.P.S. Exhibition at the New Gallery include some very fine work. (P. 734.) "Election" at the Salon, exposure calculations, etc., occupy our "responsiveness" columns. (P. 745.)

recent lecture by Mr. James Shaw before the Manchester A.P.S. popularised some of the methods employed by this well-known maker. (P. 733.)

G. Hammer Coughton, an English photographer now on his way to this country after twenty-five years in America, contributes notes on the Conventions which are successfully held in many of the States. (P. 732.)

propose of Sir William Abney's recent reminder as to the reversing of red light, Mr. H. J. Channon contributes a review of the forgotten work on this subject. (P. 737.)

Photography of Colour.—The first portion of some notes intended to convey to the photographer some right and useful notions the use of screens and plates in the photography of coloured objects appears on page 735 from the pen of Dr. G. E. K. Mees.

one of the considerations which require to be taken into account in making a "like-size" portrait are mentioned on page 731.

recent German patent for a mixture including acid sulphate of is a reminder of the use which can be made of this substance as an acid component of dry mixtures. (P. 731.)

experience of a French worker with the little-known Benham process of copper printing process is translated on page 738.

uses for three-colour cinematograph work, dark-room safe-lights, portable print-washers figure among patents of the week. (P. 739.)

conviction of a photographer canvassing without a pedlar's licence took place last week in the Isle of Wight. (P. 744.)

## EX CATHEDRA.

### Photographic Pictures in Colour.

On Monday next there will open at the house of THE BRITISH JOURNAL OF PHOTOGRAPHY a collection of the recent remarkable photographic work of the brothers Theodore and Oscar Hofmeister and their friend H. W. Müller, all of Hamburg. The recent labours of these workers in the field of multi-colour photographic printing have been seen scarcely at all at recent exhibitions, and therefore particular interest attaches to the present collection, which represents the work of the past four or five years by these gentlemen, who are the most notable of the German pictorial workers, even though they have not been seen at exhibitions so prominently as the indefatigable Dührkoop. It should be said, however, that the large size of many of the pictures makes their circulation a great tax, and moreover the brilliant colour effects present difficulties as regards hanging with monochrome photographs. As in the case of previous exhibitions, the pictures will be open free to visitors to 24, Wellington Street, Strand, on signing an attendance book.

### Dark-rooms, Dog-kennels, and the Parliamentary Vote.

As reported elsewhere in this issue, the Registration Court at Gloucester last week was the scene of a comedy in which photography of the amateur-professional type played the leading part. It was claimed for two would-be voters in the city of Gloucester that their occupation of certain dark-rooms entitled them to places on the voting register. One claimant turned out to be an insurance agent, and the other a post office clerk, yet both were put forward by the Conservative agents as eligible for the vote in respect of their occupancy of the dark-rooms, since, like the Duke of Plaza-Toro, they added "large sums to their makings." The revising barrister, however, dissented from this view, disallowed the claims, and, with a grim humour worthy of the claimants' pleadings, proceeded similarly to disallow a claim put forward on behalf of an alleged huntsman in respect of the lease of some dog-kennels. The catholic Gloucester mind!

### Telescopic Views.

Mr. J. E. Gore, in "Knowledge," draws attention to a number of astronomical fallacies—amongst others, to the one that a powerful telescope gives a near view of, say, the moon. It has been stated by people who certainly ought to have known better that the practical effect of the great Yerkes telescope is to bring the moon within a distance of sixty miles from the earth, though, as Mr. Gore points out, if such a view could be obtained, we should see very much less of the moon's surface than we do now. The telescopic image is, of course, merely a magnified view of the moon as it

appears at its proper distance, and the only true analogy is that of a near view of a small replica of the moon. The same fallacy has often appeared in connection with high-power telephotography. Many look upon the result as representing a near view of the distant object, whereas it is actually a view that it would be impossible to obtain at any nearer point than that from which it was actually taken. A photograph of a small replica at a certain nearer distance would correspond exactly with the telephoto result, but in this case the analogy is imperfect, as the photograph very often conveys no suggestion of undue smallness. The case here is, of course, complicated by the varying conditions that govern our conceptions of apparent size and apparent distance.

\* \* \*

#### Electric Light Installations.

The average professional worker has the reputation of waiting till the last minute. Thus, during the present spell of fine autumn weather the November fogs and the short days of December, with the usual rush of Christmas work, all seem a long way off. Then, when they are actually upon one, the problem of artificial lighting is considered, and work is rushed on, and often imperfectly done, so that the illuminant selected may be at once available. Now is the time, of course, to give the matter careful consideration, and ten or fifteen pounds thoughtfully expended now will in most businesses be more than regained before the end of the year. Too many, we feel sure, rely on making another appointment when sitters come on a very dull or foggy day, failing to realise that in such a business as photography it is of vital importance to strike while the iron is hot. In other words, few people are photographed for some specific reason, most simply "taking it into their head." Reference to our advertisement pages will show the variety of systems for artificial lighting, and while we should hesitate as to pronouncing any one to be the best, we shall always be glad to give help to inquirers if they will put before us the special requirements of their business, and give us some idea of the size and arrangement of their premises. While electric light undoubtedly takes first place for cleanliness, coolness, and efficiency, much excellent work is done by means of gas installations, and where current is not available gas must, of course, be utilised, or some form of magnesium flash. In any event, we commend an immediate consideration of the matter to our readers, or to those who desire to keep up to date and to make the most of the autumn season, which in many towns is the most important portion of the year.

#### Counting Seconds.

A writer in the "Photographic Month" suggests that the best way of counting seconds is to hum a march air, at the same time beating time with the foot, and also counting time in the discredited fashion that killed so many promising musicians in the past. Passing over the fact that it is a little difficult to hum a tune and count the time aloud at the same time there is a very great deal in this suggestion, for it is certainly true that many people can beat musical time very accurately, though they cannot count seconds (as from the musical idea) with any approach to accuracy. The usual method is to count quarter-seconds in the same way that "rests" are counted in music. That is to say we can count 1, 2, 3, 4; 2, 2, 3, 4; 3, 2, 3, 4, etc., allowing one figure for each quarter-second. If, however, counting is effected regardless of musical time one person may be really counting fifths of a second while another is making thirds, or even halves. Bring the musical time into play, and at once the counting becomes automatically correct. We do not much believe in the utility of counting for quarter-seconds. The best way to make a quarter-second exposure is to set the shutter to bulb and squeeze and relax the ball as quickly as possible. Half a second can be given by a similar method, with the shutter set to time. We prefer to use counting for whole seconds and it is astonishingly easy to count almost any number of seconds if one counts simply in waltz time, letting the number fill a complete bar. This is a much easier method than the one advocated by the writer in our contemporary and it is also more likely to give accurate results, so that waltz time is not so variable as march time, and is familiar to everyone.

#### A Stereo Camera for Scientists.

In reviewing a recent scientific paper that is very freely illustrated by photographic plates, we expressed a regret that stereoscopic records had not been secured instead of simple single photographs. This was only one case of many in which the use of stereoscopic apparatus would be distinctly desirable, and the fact that scientists do not make greater use of it is perhaps due in a great measure to the fact that their requirements are not apparently considered by the camera maker. Of late numbers of stereoscopic cameras have passed through our hands, but we cannot say that one of them is of the type required for scientific purposes. In such work as this the object photographed is nearly always near; therefore the lenses must have an adjustable separation. This movement is usually lacking in the majority of cameras, even in the

### THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1909.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-eighth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of over 1,000 pages, and the entire edition of 25,000 copies was sold out immediately. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1909 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

#### REFLEX CAMERAS,

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1909 will be

modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1909 will appeal to photographers the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and, wherever practicable, features of an informative nature will be added.

**\*\* IMPORTANT NOTICE.**—The attention of advertisers is specially directed to the announcement that the 60th edition of the ALMANAC (25,000 copies) will again be put in the hands of dealers and the trade on December 1, as to be well in advance of the Christmas publishing season, and the co-operation of advertisers to that end will be esteemed by the publishers.

most expensive kind, and when it does exist there is sufficient latitude of movement. Sometimes it may be necessary to make the lenses almost touch one another in order to get the images on the plate, but it is seldom possible to reduce the separation to less than  $2\frac{1}{2}$  inches, though a separation of  $1\frac{1}{2}$  inch would be quite feasible. Experimental work asingle-plate binocular is essential. In very few cases can a one-lens camera be used, and the simultaneous use of a pair of cameras renders the separation difficult worse than ever. In addition to this, the duplication of two plates instead of one means an extra addition of time and trouble that cannot be thought of in such laborious work as scientific photography. A two-single-plate camera specially suited to the photography of near objects could easily be devised, and it would be just as serviceable for more ordinary work as a usual pattern.

\* \* \*

**Mounting Celluloid film on paper for any purpose, such as the making of multi-negative test-plates described in issue of August 21 last, some difficulty may be experienced in attaching the strips of film sufficiently firmly to stand the somewhat pronounced curl—we are referring now to cinematograph, not to the photographic film, which has been rendered non-curling by a coating of the cement on the reverse side. It may therefore be well to mention a cement which has been found sufficient for any purpose. This is a solution of gelatine in acetic acid, a mixture which we believe is sold as a commercial liquid. The solvent action of the acetic acid upon the cellulose no doubt the cause of the satisfactory adhesion of the film to the paper surfaces.**

\* \* \*

**Sulphate** A German patent recently taken out for a mixture of potassium permanganate and sodium acid sulphate as an oxidising or reversing bath is a reminder of the usefulness of the acid or hydrogen sulphate of soda as a substitute for sulphuric acid. Obviously the latter cannot be conveniently used as a constituent of preparations which are used in a dry state, and in such cases the use of the salt often forms the useful purpose of providing the required constituent of a mixture without necessitating recourse to a separate glass capsule. It should be borne in mind that only one half the sulphuric acid in the acid mixture is in the unsaturated state, that is to say, that 240 parts of the pure solid compound represent 98 parts of sulphuric acid.

## IS A LIFE-SIZE HEAD IN A PORTRAIT?

It may seem a little strange, not to say superfluous, to raise such a question as this. Many, without entering the matter, would at once reply that "life-size" should be the exact size of the sitter, whatever that happens to be. This answer would be literally correct, but in the case of a portrait it is not always a literal measurement will convey a correct idea of life-size in a painting or photographic enlargement. In conversation with a professional enlarger, whose business is chiefly among professional photographers, he said that he frequently received orders to make from the photographer a life-size enlargement on a given size plate; many instances he did not carry out the instructions literally, as he knew that if he did the result would not be satisfactory to the photographer or his customer. People seem to have strange ideas as to what is a life-size portrait when it is framed and hanging on a wall. For example, we have a portrait of an elderly lady hang-

ing in one of our rooms; it is a vignettted head and bust, about 18 x 15. Many persons on seeing it have remarked, "Oh, that is life-size," whereas, by actual measurement, it is nearly an inch and a half less than the actual size of the lady's head. It is the head-dress and the small area of the whole picture in this case which conveys the idea that the portrait is the size of life.

It is generally accepted amongst artists that the average size of a man's head is eight and a half inches, and that of a woman seven and a half inches—that is, from the point of the chin to the top of the head. By the top of the head the top of the scalp is meant, and not the top of the hair; such a measurement as that would, of course, be fallacious if it were applied to men who have a profusion of hair, or to ladies whose coiffure sometimes is some inches above the scalp. In such circumstances, if the head in the portrait were made true to life-size, the portrait would appear to be above life-size, more particularly if the picture were a comparatively small one, say 20 x 16. This brings us to another point. The size—or rather apparent size—of a head depends very much upon the size of the picture itself, and the frame it is put in, as well as the position in which it is hung. If the same enlargement be hung at nearly the top of a lofty room it will appear to be smaller than if it were hung about on a level with the eye. An artist, when he paints portraits, takes this into consideration, and if he knows they are to be hung in a lofty gallery he usually makes them something larger than that of life—that is, measured by the foot-rule. This point should be borne in mind by photographers when they have a commission for a life-size portrait.

An actual life-size head, we will say, in an 18 x 15 picture, which, by the way, will include but little of the bust, framed up close, and hung on about the level with the eye, will seem to have a common, if not a vulgar appearance, particularly if it is a portrait of a lady. Whereas if it were a 24 x 18 or 30 x 24, which would include very much more of the figure, it would appear as it should do and convey a good idea of an actual life-size portrait. This is due to the amount of figure included in the picture causing the head to appear in proper proportion.

Another point for consideration is that portraits of a husband and wife are frequently required as a pair to hang side by side. It may happen that the lady has large features and a round face, also a profusion of hair. On the other hand, those of the gentleman may be small, the face thin, and possibly he may have a bald head. In these circumstances if the two portraits were enlarged to correct life-size—by foot-rule measurement—the two when hung together will not appear to match. The majority of persons seeing them would say that the lady's portrait was too large, or, possibly, that the gentleman's was too small and insignificant. In such a case as this, if life-size portraits were ordered, a far more satisfactory result would be obtained by making the lady's head a little less than actual life-size and the gentleman's a trifle larger. If that were done the portraits would appear to be truly life-size and make a satisfactory pair when hung together.

In connection with this part of the subject we may refer, by way of illustration, to a case that came under our notice a year or two back. A photographer of our acquaintance had executed an order for an enlarged portrait of a gentleman. It was a vignettted  $5\frac{1}{2}$  in. head and bust. The gentleman was thin, had very thin features, and the original portrait had been taken three-quarter face, and three-quarter figure. The enlargement gave such satisfaction that another, same size, was ordered, but this time from a different sitting. In this the sitter had been taken full face and nearly full figure. When this picture was

received by the customer it was complained of as being smaller than the previous one. We saw both pictures, and the latter one seemed decidedly smaller than that first made, while a foot rule showed that it was really half an inch larger. We mention this case merely to show that in making enlargements judgment should be exercised as to what the finished picture will appear.

Comparatively few photographers make their own enlargements, but send them to professional enlargers with, frequently, very vague instructions. This often leads to disappointment when the picture is received. Enlargers will join with us in the suggestion that the photographer should give definite instructions, say, to make the enlargement so many inches between two given points marked on a print from the small negative. This can be easily decided upon in the following simple way:—A sheet of cardboard, or paper, is taken, the size the enlargement is to be. The negative is put into the dark slide of the camera,

which is then taken into a darkened room—not necessarily an actual dark-room. The shutters of the dark slide are then withdrawn and a light placed behind the negative; an ordinary paraffin lamp will suffice—the image projected on the cardboard, and the camera moved backward until the size of the image, that it is judged to look best in the finished picture, is obtained. Then the distance between two conspicuous points, say between a button on the coat and the extreme top of the hair, is measured. These points are then marked on a print from the small negative. If then the two together are taken to the enlarger with instructions to make the enlargement to measure so much between the two points marked on the print, there will be no disappointment when the picture is received. If this were always done the photographer, through seeing an actual enlarged image, will be able to judge whether its dimensions are actually those he requires.

## AMERICAN PHOTOGRAPHIC CONVENTIONS: AN ENGLISHMAN'S VIEW.

WHEN I left England twenty-five years ago for America I had never heard of an English convention; and, as all I have heard about them I gather from the pages of the English photographic journals, I cannot be expected to know much about them; but I do recognise a distinct difference between the two, which I will endeavour to explain.

### The American Convention is Professional.

In the first place, the American Photographic Association, known by the three letters P.A. of A., is distinctly an association of professional photographers; the membership is made up from all the States in the Union and a considerable number of Canadians. They meet in convention for instruction and information first, and second for fraternal intercourse and enjoyment. There is a floating membership of about two thousand. What I mean by a floating membership is this: If the convention is held in a large city where there is a large outside population to draw from, there will be a large attendance, and photographers from the nearby towns or villages will join the association, as no one can attend or have the benefits of the convention and its exhibition who is not a member. It follows, therefore, that if the next convention is held in a city far removed from his district, the photographer who has joined for the benefits to be had in the city near him will most probably omit to keep up his membership, till it is held again in some nearby city. In this way there is always a fluctuating membership, although the membership keeps about the same number year by year.

### "The Latest" at a Convention.

As I understand it, the English convention is mostly made up of amateur photographers, and the object is not so much information or instruction as amusement, more in the manner of a picnic to some noted place or some place where there is good material for the camera. This would not command anything like so large an attendance as the convention of a professional body who are brought together to see the work of others, and compare it with their own, who come to see the latest devices of the manufacturers as to cameras, backgrounds, and other appliances for the improvement or labour-saving part of their work. For the American conventions make greater provision for the exploiting of the manufacturing part of photography than is done at the exhibition of the Royal Photographic Society of Great Britain. I know, in my experience of photographic associations in Eng-

land from 1868 to 1880, the idea was to keep out all business and commercial influences; but from my experience of American conventions from 1884 to 1908, I know that if the manufacturers and dealers in photographic goods were debarred from the meetings or conventions of the P.A. of A., the Association would lose its membership and soon cease to exist.

### Conventions v. the Photographic Press.

America is such a large country, the cities so far apart, that in many cases the conventions are the only medium by which the small country photographer can get into touch with the latest improvements either in apparatus or methods of work. I do not think that the American photographers as a whole are readers of photographic journals, as are the English. It is within the last few years that we have had a weekly photographic journal. There are now two, but they are not nearly so large, and, to judge from the contents, find some difficulty in keeping up the interest week by week; so that it may well be that the information and instruction that the American photographer seeks in his convention the English photographer gets through his weekly photographic journal.

But it is even doubtful if one can call American conventions successful, if we judge by the number of photographers attending at the annual conventions of the P.A. of A. There are about fifteen thousand professional photographic establishments in the United States. Reckoning on the very conservative estimate of one assistant to each gives a total of thirty thousand. The average attendance at any convention is about eight hundred. It has reached one thousand, but that is exceptional.

### The Change in America.

The fraternal features of these conventions have increased with time goes on. When in 1884 I wrote for "The British Journal of Photography" about the convention at Cincinnati, I said that in America there was not the interchange of thought and experience among photographers that I had seen in England; when an American photographer worked out one thing that he thought was an improvement, he rushed off to the Patent Office to secure it for himself. It was so then, but now that is not so much of that sort of thing. Men found that by the interchange of experience both could gain without loss to either, so the fraternal spirit now dominates the conventions, and

(as we saw at Detroit last July) some of the best-known photographers giving up their time, and demonstrating their methods of work, both in posing and lighting, while in the case of Mr. Illips some methods of securing pictorial subordination by elopment were shown. These are some of the methods that the American conventions a success.

Another thing which I think deserves mention is the systemated, I think, by the New York State Association of sectional

clubs as feeders to the central body. Each city in the State has its section, which is affiliated with the central body, and includes the photographers not only in that city but all who wish to join within a certain radius of that city. This has proved such a success that other States—Pennsylvania and Virginia and others—are taking it up, and the system seems destined to further advance the social status of photographers and to greatly add to the fraternal feeling.

G. HAMMER CROUGHTON.

## “GOOD” SLIDES AND “FINE” SLIDES.

[An unconventional report of a lecture given by Mr. Jas. Shaw before the Manchester Amateur Photographic Society September 8.]

PERHAPS you have no personal knowledge of Mr. James Shaw (Rothenburg and Manchester). Let me tell you, then, how to be identified. You see a man upon the pavement in conversation with his friend. He pulls himself up straight, he raises his hand above his head, he lunges forward, dives to half height, and at the same moment brings the raised hand and closed first a thud into the open palm of the other. Now, if in addition to this you observe the said friends standing well back for fear of accidents you may know assuredly that this is Shaw. He talks with enthusiasm. He makes “fine” slides with the same material. Indeed, enthusiasm, experience, and a few things bought of a chemist’s are all he seems to use. If you suggest “you are not on slides” he would resent this, for, as a matter of fact, there is nothing for mere slides; he likes “fine” slides. The subject of his lecture before the Manchester Amateur Photographic Society was, therefore, only a clear reflection of himself—“the differences between good slides and fine slides.” Shaw has no aid. He is restless in the rut of other men’s wheels, and will do anything to attain his end, if only the end promise “fine.”

As already remarked, when Shaw talks to you he must have a sink. So it is when he works. His sink is a small swimming-bath on legs. There is Thomas’s formula to the right of him, Howard Farmer to the left of him, mercury in front of him, the slide which must be “fine,” or else be a cover-glass, is placed with a zeal worthy of French tirailleurs before Hougoumont. A portion of the slide seems to hang fire in development; you go, his finger into the dish; you expect to see the finger protruding through the bottom of the dish; but, no, it rests upon the slide, and now the warm ball of the finger is being gently pressed over the lagging high-light detail just to coax it into visibility. You think he is working in a haphazard way. He is not. He knows what he wants before he begins, and then he goes for it.

It is not to come to particulars.

Shaw has a slide—this has stood by him for years—which he uses as a standard gradation. There must be nothing in any slide higher or lower in tone than the lights and shadows of this slide. He seldom tests by means of the lantern. When a standard slide is projected upon the screen the shadow of the pointer, when held between the lantern and the screen, can be clearly seen as denser than the densest portion of the slide. This proves that light is passing through the densest portions, and that light should pass through is essential to the consistency of the shadows. In other words, when you can hold

your hand before the densest shadows of the picture upon the screen without being able to see the shadow of your hand distinctly, the slide does not belong to the order called “fine.”

If the slide be judged for density in the hand, then one must be able to read print through the densest parts, while the high-lights when laid upon a piece of white note-paper, must appear veiled.

It is quite needless to repeat Thomas’s formula, as it is to be found in every text-book. But Shaw never uses it at full strength. Fond of warm tones, he gives—for such tones—three or four times normal exposure, and lets the developer down to quarter, or even less, strength. Although he swears by this formula he is not wedded to it. He flirts with ferrous oxalate when he wants a pure black and very transparent shadows, but realises that for this developer his exposure must be just correct. When he has a particularly hard negative to deal with redolinal is his refuge.

Does he get a good slide every time? No, he does not, but he can afford fifty per cent. of failures, since for every slide he needs a cover-glass. If one slide is “good” and the other is “fine” he uses the “good” one to cover the “fine” one. No good slide-maker buys cover-glasses; these are made for and sold to beginners. That is Mr. Shaw’s aphorism—uttered perhaps in a vein of irony. As to toning, Mr. Shaw is generally satisfied with the colours given by the three developers named, but if he desires a blue he uses the gold toning bath rich in gold. This does not clog the shadows, and yields a good pure blue.

Uranium seems with him to have stood well. Some uranium-toned slides ten years old were shown, and these seemed to have remained in excellent condition.

Perhaps, however, he makes the greatest use of mercury. This he uses for three distinct purposes: (1) To change the colour of the slide, (2) to intensify a weak slide, and (3) to treat a purposely under-developed slide for the purpose of getting a quality which he cannot get in any other way. Slides treated with mercury he redevelops with the hydroquinone solution. Howard Farmer reducer he makes great use of to secure brilliancy; and to those who desire to get a good slide from a hopelessly thin negative he recommends the following:—After exposure develop the slide until it is so dense that no light, however strong, could project an image of it upon a screen, then reduce the slide in the above reducer till satisfactory.

The whole lecture was illuminating, and was greatly enjoyed by all who heard it.

HACKNEY PHOTOGRAPHIC SOCIETY.—The annual exhibition will be held at the King’s Hall, Hackney Baths, from November 4 to 7, inclusive. In the open classes silver and bronze medals will be offered at the disposal of the judge, Mr. A. H. Blake, a gold medal also offered for the best picture in these three classes. Entries

close October 19, and entry forms are now obtainable from the secretary, Mr. Walter Selfe, 70, Paragon Road, Hackney, N.E. It is stated that exhibits will be collected from the R.P.S. and Salon exhibitions, without additional charge, on receipt of the signed official card.

## THE AUTOCHROMES AT THE NEW GALLERY.

WE were not able to fully review the Autochromes last week owing to the fact that they were not arranged in the show-cases. A second visit, however, fully confirms our first impression that, as a whole, the collection is a remarkably good one. The method of showing is also very successful by daylight. They are fixed in frames inclined at an angle, and are viewed in horizontal mirrors placed underneath, the only defect being that a double image is sometimes apparent, especially when the slides are very brilliant. The quality of the mirror-glass no doubt has much to do with this. At night the result is not so successful as by day, owing partly to the want of sufficient light and partly to its yellowness. Faintly tinted blue filter-screens laid over the slides at night and removed in the day-time would no doubt greatly minimise the colour trouble, but the difficulty of obtaining sufficient light is obviously rather a serious one in the circumstances, and those responsible for the arrangements are certainly to be congratulated on the great improvement that is manifest in the present arrangements as compared with those of last year. We imagine that we shall not be far wrong if we attribute the success of the present arrangement to the efforts of Mr. McIntosh.

We have already referred to the jewel study, No. 519, by Mr. H. O. Klein, as representing the lustre and beauty of the precious stones very perfectly. Unfortunately, this example is in one of the worst positions for good illumination, but careful inspection will reveal the peculiar qualities to which we referred. This transparency is, however, seen to greatest perfection in the hand. Nos. 520 and 521 are by Mr. Walter Barnett, and the first, entitled "At the Old Leather Bottle," is a beautifully soft example, full of delicate colouring, but perhaps also rather too full of subject. The child standing in the doorway is quite charming, and we think this young lady deserved a plate to herself. "The Heart of the Forest" is rather more ambitious—full of strong colouring, with some beautiful sunshine effects, but rather too artificially classic in subject to be convincing on an Autochrome plate. Unfortunately, both Mr. Barnett's fine pictures are somewhat marred by double reflection. These are the three first pictures on the catalogue and on the stands, but after these three the numbering of the exhibits is very erratic. The catalogue order is apparently disregarded, and it is in consequence very difficult to preserve any particular sequence. From this point we, therefore, consider the slides in subjects. Taking the landscapes first, as we have already dealt with two of them by Mr. Walter Barnett, Mr. Imre Belhazy has in Nos. 543 and 544 some most delightful studies of light and shade. These are perfect little pictures, well selected and composed, and showing beautifully cool, soft shadows coupled with warm sunshine. Again, in 545, "A Pastoral," Mr. Belhazy shows us some beautiful effects of sunlight on foliage in a country lane, together with perhaps the best representation of a sky that we have yet seen. The subject is more familiar than in the other two, but the result is equally charming. In 547 Mr. Andrew Bacsa also rivets attention with a light effect that attracts one with its suggestion of coolness. This also is a very pleasing little picture, showing a quaint out-of-the-way corner that might not have presented any possibilities to a less observant eye. Both these exhibitors are from Budapest, and their work is new to us. We hope to see much more of it in the future. A very effective picture is Mr. W. Taylor's "St. Michael's Mount" (565), in which the distance and the strip of sea visible have almost a paint-like quality. No. 566, also by Mr. Taylor, is worth study. Mr. G. C. Laws has a very fine subject in "Bluebells" (No. 567), while in 569 to 572 Mr. U. M. Jones shows a beautiful little set of four landscapes. Mr. W. Partridge, in "The Gardener's

Cottage" (No. 578), has a pleasing study of greys and greens, while his "On Welsh Mountains" (No. 579) represents a sunlit Welsh valley. In 533 he shows us one of the old-fashioned types of country cottage gardens, with the wealth of blossoms that usually characterise them. Mr. Rowland S. Potter also deserves congratulations for his two exhibits, Nos. 668 and 669, the first of which is a study of autumn tints, while the second shows some Swiss chalets in a sunlit corner of a mountain pass, the whole forming a very attractive, even though very little, picture. Numerous other landscapes are to be seen, and they are all worth attention, though we have not space to mention them all. For some reason or other we failed to find in the show-cases some of the pictures listed in the catalogue, and we are therefore unable to refer to the productions of some well-known workers.

Figure studies and portraits are also fairly numerous, and Mr. Warburg is a prominent and very successful exhibitor. In No. 527 visitors will recognise a well-known character at the Franco-British Exhibition, where Mr. Warburg has also found several other excellent subjects. No. 536 is a good example, showing a bold and successful colour scheme. Dr. Drake-Brockman has some good portraits in Nos. 621 to 625. These are all excellent from the technical point of view. They are very true in their rendering, and the fur in No. 621 may be specially noticed. No. 540, "Field Flowers," by Andrew Bacsa, is a figure study worth close attention, as the figures themselves are very soft and delicately rendered, though, to our minds, the very bright green grass and yellow flowers strike a slightly discordant note.

In the general subjects Mr. Ellis Kelsey is very successful. All his still-life subjects are perfect, No. 530, "Roses," being very strong and true flower study, while the strawberries in No. 585 are very realistic. No. 586, "All Souls' Church, Eastbourne," is one of the few architectural subjects, but it does not strike us as so successful as the rest of Mr. Kelsey's work. The colouring is rather hot, but possibly the church decorator has something to do with this. Mr. S. A. Pitcher's "South Aisle, Gloucester Cathedral," No. 646, is a transparency worth notice for its fine representation of stone.

Mr. Edward J. Bedford has a uniformly good exhibit, including a landscape in which some rich yellow gorse forms the principal object. His "Springtime" (No. 658) is also worth special mention. The rest of his work is mainly of the nature-study type, and we would mention No. 655, "Larvæ of Emperor Moth," as a specially good example. Mr. Martin Duncan, in Nos. 643 and 644, and Miss L. E. Bland, in Nos. 587 to 597, also show some excellent nature studies. No. 593 is a good example of the effect of protective colouring, as the young gulls are by no means easily detected amid their rocky surroundings. The beautiful colouring of the rocks in some of Miss Bland's pictures is well worth noticing. In more rigidly scientific work the exhibition is rather strong, and in regard to this we have a slight grumble to make. We are certainly of the opinion that exhibits such as No. 618, excellent as they may be technically, are not quite in place at the New Gallery, and we think that for several reasons the technical selecting committee would have been better advised if they had left this one at least out of the show-cases. Dr. Drake-Brockman's series of slides illustrating the evidence to hand in the Middlesbrough murder case of this year are a very interesting set, and, though somewhat gruesome, show what an important part colour photography may play at times. In his pathological studies, No. 617, "A Fading Black Eye," may arouse interesting memories of a painful or pleasing character according to the person most concerned. Messrs. Arthur Barfield and J. I. Pigg show a number of fine polariscope subjects, and Mr. H. O. Klein some spectra of the flame arc. All these

be studied with interest by those interested in pure science at the same time the fine colour effects will no doubt attract many who do not understand the subjects.

We are glad to see that still-life subjects of the type that were common last year, and that this year fill the majority of the spaces at the Salon, are very few at the New Gallery. Those that exist are good specimens; but the more experienced Autochrome workers have evidently realised that this type of work is too easy to be worth very much attention, and the success that attended their efforts in the direction of much more serious

and more difficult work is really remarkable. Last year the landscapes were all more or less indifferent, and doubts were expressed as to the possibilities of the Autochrome plates in the direction of pictorial work. This year these doubts should soon be put to rest by a study of such work as is shown by Messrs. Belhazy, U. M. Jones, W. Partridge, Rowland S. Potter, and others. Another pleasing feature is the absence of the wild and irritating colour discords that characterised some of the early work, and that are still to be seen in the productions of those whose appreciation of colour appears to be defective.

## THE PHOTOGRAPHY OF COLOURED OBJECTS IN PRINCIPLE AND PRACTICE.

[The following article, which will be completed in a succeeding issue, to be issued by Messrs. Wratten and Wainwright, who specialise so well explains matters in the practice of orthochromatic photography, in connection with the permission of his firm we quote from advance sheets of the book. Our readers, for the sake of the chapters on portraiture, landscape, reproduction work, and the tri-colour process, all in relation to the photography of coloured objects. Messrs. Wratten and Wainwright will shortly publish the volume at a nominal figure.—Eds. "B. J."]

At the commencement of these chapters, which are essentially concerned with the analysis and photography of colour, it will be well for us to get a definite idea as to what is meant by "colour," and with what physical phenomena colour is associated.

The nature of colour is involved in the conception we obtain of the nature of light. The nature of light has long been a matter of speculation, and it was generally held that perception of light depended on the reception by the eye of small discrete particles shot off from the source of light; just as at one time it was held that the perception of sound depended upon the vibration of the ear drum of small particles shot off from the source of the sound. This theory of light has the advantage that it immediately explains reflection; just as an india-rubber ball bounces from a smooth wall, while it will be shot in almost any direction by a heap of stones, so these small particles would be reflected from a polished surface, while a rough surface would scatter them. This theory of the nature of light appeared plausible until it was found that it was possible, by dividing a beam of light and slightly lengthening the path of one of the waves, and then re-uniting them again, to produce periods of darkness, similar in nature to the notes produced in an organ pipe where the interference of the waves of sound is taking place. It could not be imagined that a reinforcement of one stream of particles by another stream of particles in the same direction could produce an absence of particles, while the analogy with sound suggested at once that, just as sound was known to consist of waves in the air, so light also consisted of waves.

Light cannot consist of waves in the air, partly because we know that it travels through interstellar space, where we imagine there is no air, but also because the velocity of light, nearly 186,000 miles per second, is so great that it is impossible that it could consist of a wave in any material substance with which we are acquainted. It is, however, supposed that there must be something spread through all space and all matter, a substance which is termed the ether, and that light consists of waves in this ether.

Now, just as in sound we have wave notes of high frequency, and notes of low frequency, so with light we may have different

issues, is composed of several chapters from a book by Dr. C. E. Mees, to be issued by Messrs. Wratten and Wainwright, under the title of "The Photography of Colour." Dr. Mees' photography that frequently presents difficulties, that by

The full text of the latter we would recommend to the perusal of landscape, reproduction work, and the tri-colour process, all in relation to the photography of coloured objects. Messrs. Wratten and Wainwright will shortly publish the volume at a

frequencies of vibration, some falling upon the eye at very short intervals, while other waves are of only half, or even less frequency.

Since the velocity of light is the same for waves of different frequencies, it is clear that the waves of high frequency will be of shorter wave length than those of low frequency, the length of a light wave being the distance from the crest of one wave to the crest of the next.

The wave length of the light, like the velocity, will vary with the medium in which the light is travelling. For instance, when light is travelling through glass it will only have about two-thirds of the wave length of the light travelling in the air. But it is convenient to consider simply the wave length of light as the length of the wave in free ether, or, for practical purposes, in air. White light consists of vibrations of many degrees of frequency, i.e., it consists of waves of various lengths, and a mixture of waves of all lengths in certain proportions forms what we term white light. If, instead of allowing this heterogeneous mixture of waves to fall upon the eye, we omit waves of certain frequencies from those entering the eye, then the brain will receive a sensation of colour: that is to say, colour is associated with wave length. White light being made up of waves of different lengths may be regarded as being made up of light of various colours, and by different devices may be split up into these colours. When this is done there is obtained what is known as the spectrum.

Since different lengths of wave correspond to different colours, the spectrum corresponds to a scale of different length waves. The following diagram gives a simple arrangement of the spectrum, the numbers representing the length of the waves and the colours being placed against them. (Fig. 1.)

It will be seen that the visible spectrum extends from 7,000 to 4,000, and is equally divided into regions which may be broadly termed:—

Red .....	7,000—6,000
Green .....	6,000—5,000
Blue Violet .....	5,000—4,000

If we make a filter which only lets through the portion of the spectrum between 6,000 and 7,000, then we should call that filter a red filter; a filter letting through from 5,000 to 6,000 would be a green filter; and a filter letting through from 4,000 to 5,000 would be blue-violet in colour. Thus from the spectrum we already derive the idea that light can be divided into three

colours, which we may call the primary colours, red, green, and blue-violet.

Remembering this conception of light, let us address ourselves to the question of why a given filter is red. It will appear red because it only lets through red light, but white light consisting of red, green, and blue-violet is falling upon it, so that clearly it is red because it stops or absorbs the green and blue-violet light.

Fig. 1.

Similarly, a piece of red paper is red because it reflects red light, but it has falling upon it white light consisting of red, green, and blue-violet, so that it must absorb the green and blue-violet light, not reflecting them, and only reflecting the red light. We are therefore justified in saying that anything which absorbs green light and blue-violet light together will be red.

It is this aspect of colour, that objects are coloured because they absorb, which must be clearly and definitely understood if the best results are to be obtained in the photography of coloured objects. Unfortunately, however, the conception of colour as an absorption is not common, though I believe it to be the most useful one, and it will be necessary for me to somewhat elaborate this subject in order to prevent misconceptions arising. It seems to me that we should form the habit of considering a red object, not as one that reflects red, but as one that absorbs green and blue-violet.

The importance of this definition is that it defines "red" without reference to the colour of the incident light. Take a scarlet book and examine it by a light containing no red, such, for instance, as the mercury vapour lamp, in which red is almost entirely wanting. The book will no longer reflect red light, because there is no red light for it to reflect, but it will still absorb the green and blue-violet light of the lamp, looking black; it has not changed its nature, and we should still be justified in saying that it is red if we define red as we have done above.

In the same way, a yellow object is not one which reflects yellow light (there is very little yellow light indeed in the spectrum, and if an object reflected only yellow light it would be so dark as to be almost black), but a yellow colour is due to blue absorption. It reflects the other two components of white light, green and red, so that we should be justified in saying that yellow light consists of green light plus red light, but for our purpose I want to consider yellow simply as a lack of blue, that yellow is minus blue, so that if you have a beam of yellow light and add blue light to it, you will get white light. Now what is green? Well, since white light consists of red light, green light, and blue light, green is clearly white light minus red and minus blue; and a green body is one which absorbs both red and blue, the difference between a green object and a yellow object being that the yellow object absorbs blue only, whereas the green object absorbs the red light which the yellow object reflects.

We can now make clear what is meant by complementary colours. As is shown in the diagram, white light consists of red light, green light, and blue light. The next section under this shows the blue blotted out, leaving the mixture of red and green, that is, yellow. We should say, then, that yellow is complementary to the blue-violet. In the same way, in Fig. 2, all green and blue is blotted out, leaving only red, so that red is complementary to green-blue. In the bottom diagram all red and blue is blotted out, leaving only green; green then is complementary to this blue-red mixture, which is usually known as magenta.

In general, then, the light absorbed by an object may be said to be complementary to that reflected by it.

So far, we have only considered intense colours. We have imagined that a red object absorbs the whole of the green and the blue-violet light, that is to say that its absorption is complete. But most things have only partial absorption—the absorption is incomplete.

Red	Green	Blue
Red	Yellow	Blue
Red	Green	Blue
Red	Green	Blue

Fig. 2.

Partial absorption can be in two forms, it can be gradual, or it can be sharp; thus, if you take a photograph of a spectrum and put in front of the spectroscopist a solution of erythrosine, then that erythrosine will cut a clean patch out of the spectrum between 4,800 and 5,500, as is shown in the photograph (Fig. 3 and 4). But if you put in front of the spectroscopist a cell containing gentian-violet you will get a gradual diminution of intensity between about 4,700 and 6,200.

Fig. 3.

with the least light transmitted about 5,800. Thus different dyes and different substances give different classes of absorption, the two kinds being roughly sub-divided into (1) sharp absorptions, and (2) gradual absorptions.

Let us examine the effect of a single sharp absorption band different parts of the spectrum. First, consider a sharp absorption band situated in the red about 6,500, and producing a total absence of red in this part. The remaining colour consists of

Fig. 4.

the blue-violet and all the green, with some of the red. The actual visual effect of the mixed colour is what one might expect a "sky-blue." Imagine this band to shift so as to absorb in the orange; say that it absorbs between 5,800 and 6,100; the colour now will be a light violet-blue, because there is a great deal of red being transmitted and less green. If the band now shifts into the yellowish-green from 5,400 to 5,900, it will absorb a great deal of the green and none of the red, and its colour will

ome bluish-purple. As it shifts lower in the green towards blue this purple becomes a reddish-purple, so that when the d is situated at from 5,800 to 5,300 we have what is generally

Fig. 5.

wn as magenta in colour. As the band shifts towards the e, the blue fades out of the magenta, green taking its place; hat when the band is from 4,700 to 5,100 the colour is a sort

of orange, and as the band moves into the blue-violet, allowing the whole green and red to pass, but stopping more of the blue-violet, the orange becomes a yellow, and finally a lemon-yellow. So that if we imagine a single band to pass down the spectrum, we get a change from light sky-blue through purple, magenta, orange, and yellow, to lemon-yellow. (Fig. 5.)

Now it will be seen that there is one class of colour which does not enter at all into this series, namely, the greens. There is really no visual suggestion of green in any colour formed by using a daylight spectrum and absorbing one narrow band only. In order to get a green, we must have an absorption both in the red and in the blue. Thus, if we absorb the extreme red and also the extreme blue, we shall at once get a green, and as these two bands vary with regard to each other, we shall obtain various shades of greens. Thus, if the red absorption band is very strong and the blue absorption band is weak, we get blue-greens; if the red absorption is weak, and the blue strong, yellow greens.

Green is almost the only common colour due to two absorption bands, and other colours which on analysis prove to have two absorption bands generally tend to be mere variants in hue of some colours which we have already discussed under the heading of single absorption bands. A brown colour is fairly common, and the bands of a brown are of a gradual absorption type, generally extending through the blue-green with a transmission band in the violet; that is to say, a brown is really a degraded orange, and is a variant on the colour described as orange, resulting from a single absorption band in the blue-green.

C. E. KENNETH MEES.

(To be continued.)

## RAYONS CONTINUEATEURS AND NEGATIVE RAYS.

AVING some time ago read up a little of the history of the photo-chemical action of the less refrangible rays of the spectrum, it has occurred to me, apropos of Sir William Abney's reference to that important and strangely neglected subject in the August number of the "Photographic Journal," that a few notes upon the action of these rays might perhaps be interesting.

It was very soon after the invention of photography that the peculiar photo-chemical effects produced by light of the greater wave-lengths was first observed, and M. Edmond Becquerel made the first contribution to our knowledge of the subject. This was in 1839, when he presented a most valuable paper to the Académie des Sciences, in which is described his discovery of the action of the *rayons continueateurs*.<sup>1</sup> The paper evidently made a great impression on the scientific men of the time, and an extremely favourable criticism upon it was given in a report by Biot, in which the author, a very young man, was highly complimented. Becquerel, in his paper, considered the rays of the spectrum as falling into two classes: the first, which he described as *rayons excitateurs*, included ultra-violet, violet and blue; the other class comprised those in the green up to the red end of the visible spectrum, these being the *rayons continueateurs*. The first sort have, as is well known, a direct action on photographically sensitive matter, but the *rayons continueateurs* were found to have the peculiar property that, while they are inactive in regard to a previously unexposed photographic plate, they have a strong effect on any image already imprinted on the plate. Thus they have no power to initiate, but can only on work already commenced, and a weak, insufficiently exposed image can be greatly strengthened and improved by exposing the whole surface for the requisite time to even illumination by the *rayons continueateurs*, which will increase the intensity of the stronger parts, while leaving untouched those which were not impressed in the original exposure. His conclusions were founded on experiments made with Daguerreotype plates and with papers coated with

silver chloride, and with silver bromide. In all cases the same results appeared. The continuing action on Daguerreotype plates was found to be so effective that images which had received ordinary exposures could be developed without the use of mercury, simply by exposing the plate to light behind red glass. Soon afterwards Gaudin produced some very successful results by this method of development with the *rayons continueateurs*, but found that yellow glass was to be preferred for that purpose.

Within a short time of Becquerel's discovery, another phenomenon, produced by some of the less refrangible rays, was observed, which was apparently in absolute contradiction to the former. So far from continuing and strengthening the impressions produced by the more photographically active light did these rays prove to be, that they counteracted the effect and undid the work of that light. Sir John Herschel seems to have been the first to notice this action, but after full consideration was inclined to attribute the effects shown, not to any negative action, but merely to the secondary effect of the heat of the red rays, leading to "the maintenance of the paper at those particular parts in a state of superior dryness to the surrounding parts, by which its sensibility is materially diminished." It was Dr. J. W. Draper, in 1842,<sup>2</sup> who first asserted the existence of rays having a negative action, which he did very confidently, stating that "there is a class of rays commencing precisely at the termination of the blue and extending beyond the extreme red which totally and perfectly arrest the action of the light of the sky . . . these negative rays seem almost as effective in protecting as the blue rays are in decomposing iodide of silver." Draper, however, seems to have been rather an unsafe investigator, and the results he showed were not found to establish his theory very satisfactorily. It will be noted that these negative rays of Draper cover exactly the same portion of the spectrum as the *rayons continueateurs* of Becquerel, to which the latter attributes precisely opposite qualities. It seems a strange contradiction, and yet there is little doubt that both observers were to a great extent in the right. There are evidently

<sup>1</sup> "Comptes Rendus" (Savants Etrangers), 8, 2nd Series, p. 373.

<sup>2</sup> "Phil. Mag.," 1842, p. 313.

two opposing actions induced by the rays at the red end of the spectrum and, accordingly as circumstances favour the one or the other, so positive or negative action will be found to follow.

Little more seems to have been heard of the question of negative rays till 1846, when a reference to their retarding action by Lerebours led to the publication of a preliminary paper by Foucault and Fizeau<sup>3</sup> who had been engaged a long time in investigations regarding the photographic action of the spectrum, and had already, in 1844, deposited a sealed packet with the Académie des Sciences containing an account of the principal conclusions arrived at. Their experiments consisted in subjecting Daguerreotype plates, previously exposed for a short time to white light, to the action of a very pure spectrum and developing the images thus produced, with mercury vapour in the ordinary manner. They found that, up to line C, the whole spectrum on the violet side gave a more or less strong positive impression, so that all the rays from the violet to the orange had a positive action. Those rays on the other side of C, the red and the ultra-red, had always a contrary action, the image being weaker than the ground, and over part of the image the action of the pre-exposure was completely undone, the silver plate remaining entirely bare in that place after development. With varying lengths of exposure to the spectrum, it was found that the position of neutrality was shifted, and the very interesting observation was made, as regards a certain part of the orange rays, that "the act in regard to a sensitive layer already imprinted by white light in which, photographically speaking, the violet dominates, as if at first they destroyed its effect, in order afterwards to modify this layer in a manner special and peculiar to themselves." This evidence of conflicting action is significant. The investigators had also experimented with sensitive papers and constructed various intensity curves, etc., but an account of all this was to be deferred till the production of a memoir, which it was their intention to present

<sup>3</sup> "Comptes Rendus," 23, 1846, p. 679.

later on to the Académie, but which, I fear, never saw the light. Becquerel criticised the foregoing communication rather severely but his objections did not appear to be very convincing.

After this the whole subject seems to have dropped out of not for a long time. Some patents were taken out for employing yellow light in various ways for the purpose of accelerating exposures. Daguerreotype work, and I believe at one time such methods were rather freely employed, but after the discovery of more rapid methods of photography were soon put aside and the whole matter pretty nearly forgotten. Bunsen and Roscoe, fifteen years later, asserted that the facts established in the most valuable investigation carried on by them at that period showed that the special property of "the so-called *rayons continuaturs*" had no actual existence, their verdict was probably widely accepted. But an examination of their arguments seems to show that they were not very well acquainted with the subject on which the decision was given. The remarkable facts which they had discovered as to photo-chemical induction explained well enough the effects resulting from supplementary exposure to white light in photographic processes, but, by very few experiments, they might have convinced themselves that the actions of such supplementary exposures and of *rayons continuaturs* are totally different things. It is even possible that *rayons continuaturs* may have produced slight inaccuracies in some of their work. In many of the experiments, tints printed on paper coated with silver chloride had to be compared with a scale on the same material, both scale and test-pieces being unfixed. For this work a powerful sodium light was used which was considered as quite safe, having been proved to be entirely without action on unexposed paper. It is not certain, however, that such a light would be without continuing action, and the scales may have been falsified by it, to some extent, without the investigators suspecting it.

H. J. CHANNON

(To be continued.)

## PHOTOGRAPHIC PRINTS BY THE CHROMATE OF COPPER PROCESS.

(A Paper in "La Photographie des Couleurs.")

THE process worked out by C. E. Benham, in which bichromate of copper is used, has been known for some years, although very little used. It consists in sensitising by artificial light a paper which has been well sized with the following solution:—

Copper sulphate .....	8 gms.	.....	$\frac{1}{2}$ oz.
Potass. bichromate .....	15 gms.	.....	$\frac{1}{2}$ oz.
Distilled water .....	170 ccs.	.....	6 ozs.

This is filtered and kept in a yellow bottle, and preserves its properties under these conditions indefinitely.

M. Dillaye recommends the use of ammonium bichromate, as being more rapid and giving better detail. His formula is:—

Potass. bichromate .....	7.3 gms.	.....	114 grs.
Ammonium bichromate ...	8.5 gms.	.....	130 grs.
Copper sulphate .....	8 gms.	.....	$\frac{1}{2}$ oz.
Water .....	170 ccs.	.....	6 ozs.

The author has found, however, that these two formulæ work equally well. The paper, sensitised with either of the above, is dried in the dark, and is then ready for use. It is exposed under a negative in the printing frame and progress of the print watched, as a brown image is gradually formed on the golden yellow ground of the paper. When the finer details begin to show, almost as in the platino-type process, the print is well washed in cold or tepid water, in order to completely remove the excess of bichromate. The highest lights of the print and the unexposed edges of the paper should then appear white when held up to the light. The general fault among those first using the process is to cut the washing too short.

### "Development."

When washing, the print is placed in a dish, face downwards (in order to shield it somewhat from the light), and the water changed fairly frequently, particularly at the first stage of the washing. The image which has been sufficiently washed appears somewhat reduced in intensity, and is of a faint greenish colour on a white ground. For

convenience we will call this the primary image, which has now been "developed." This operation may be done at once, or at a later stage after the print has been dried. Development is done with pyrogallol acid, dissolved at the time of use in water. In this process the print at first appears to fog and veil, but at the end of about a minute it assumes a fine sepia tone and the details re-appear. The clearness of the print is dependent upon keeping the pyrogallol solution free from colour; when once the depth given by the process has been reached further treatment will not increase it. There is, therefore, no need to hurry the removal of the print from the bath. Further, any possible fog on the print may be avoided by adding an acid to the solution. The whites then remain perfectly clear. The following formula has proved successful:—

Pyro .....	1 gm.	.....	45 grs.
Acetic acid, glacial .....	10 ccs.	.....	1 oz.
Water .....	100 ccs.	.....	10 ozs.

No doubt other acids might be used, such as citric. When development is finished the print is washed in several changes of water and dried, becoming thereby a little darker. It is an advantage finally to treat the print with an encaustic paste before mounting. The Benham process depends for its success upon the observance of certain simple and necessary precautions, that is to say, exposure must be just right, washing must be thorough, and the developer must be acid. Moreover, the paper sensitised must be of a suitable kind. Papers sized with resin or arrowroot give a very feeble print; good results it is necessary to use papers strongly sized with gelatin, such as those used for single transfer, but still having a matt surface. Papers which, when examined by reflected light, show numerous small shiny points, give only grey and fogged prints, and the same thing happens in the case of papers having a baryta substratum. It is a safe rule to choose the paper as for the oil process, or to take a paper with a very slight resin size, and add to the sensitising solution, at the moment of coating, a fairly large proportion of g

ne, such as that employed in preparing carbon tissue. In this case, however, it is difficult to avoid markings; with a transfer paper giving a good coating of gelatine the Benham solution distributes itself well, being readily absorbed by the gelatine. Sensitising is thus done very easily, a fine sponge or a soft brush being used; any little markings disappear of themselves when the paper is dried. The sensitised paper will keep several days if stored in a dry place, but it is better to employ it the day after making. It is fairly sensitive, almost as sensitive as platinum paper.

#### Reduction and Intensification.

The image, which is somewhat veiled, can be cleared by passing the print into a 1 per cent. solution of oxalic acid. The image is thus reduced as a whole and the contrasts are not increased. If it is desired to give the print more contrast, or if the veil on the print is at all pronounced, it is well to adopt the method customary in the use of over-exposed gum prints. The print is laid, face up, in a dish, and a solution of about one-fifth strength of ordinary commercial Eau de Javelle. The gelatine of the paper tends to dissolve and assumes a soapy character under the finger, but it is then gently rubbed with the finger or a soft bit of cotton wool under the liquid, particularly on parts which it is wished to lighten. A perfectly pure high-light (the white of the paper) can thus be obtained if necessary; but traces of the Eau de Javelle are removed by washing, and the print is dried. This expedient will give the most brilliant effects from weak negatives. If the Eau de Javelle should be allowed to act too much it is possible, after the print has been dried, to re-develop it in pyro, but in any such treatment as this it is essential that either the pyro or the Eau de Javelle should be completely removed from the print by washing before subjecting it to treatment with one or other of these substances, since the two together in the print will give a reddish stain, which cannot be removed.

It will be found that in washing the print bearing the primary image it is impossible to obtain a pure white if the paper has been too much exposed. In this case, before the primary image is developed (in the acid pyro), the print should be placed for about a minute in a 1 per cent. solution of sodium sulphite, washed for a few minutes, and then developed in the acidified pyro solution. It will then be found that the image develops almost as red chalk, whilst the ground of the print assumes a rose colour, which latter disappears whilst the print remains in the developer, and there is finally obtained an image of an orange colour which is less intense than that which could have been obtained by the ordinary development without sulphite.

It is also possible, in the same circumstances of over-exposure, to develop the primary image, not in pyrogallie acid, but with a strong solution of gallic acid. One thus obtains a somewhat weaker print but with better detail.

#### Intensification.

In the case of an image which is too weak, due to under-exposure, the print should be placed in a solution of 1 per cent. potassium chromate in 500 parts of water, in which the print will gradually increase in strength, assuming a brownish tone. The action is stopped at the desired stage; if taken too far the effect may be to veil the print.

#### Toning Processes.

If the print bearing the primary image be immersed in the solution of a metal, such as silver, iron, or lead, the bichromate of which is insoluble in water, this latter metal will replace, to some extent, the copper in the primary image. The treatment is followed by washing and the print is then developed in the ordinary way. In the case of silver the final tone is brownish-red. As before development it is necessary to remove the excess of silver salt by a bath of hyposulphite, there would not appear to be any great advantage in this method. In using it, however, with the primary image, it should be placed in a weak solution of silver nitrate, next in a bath of hyposulphite, and then developed.

To tone with lead the print bearing the primary image is placed in a solution of acetate or nitrate of lead, well washed and fixed. The excess of lead salt is difficult to remove by washing, and is liable to veil the print, although a treatment with oxalic acid or Eau de Javelle will put matters right. The colour of the lead-toned print is a chocolate. The most interesting toning agent, however, is iron, which gives prints of bistre tone, the best method of work being as follows:—The primary print is dipped in the pyro developer given

above, to which has been added 10 ccs. of a strong solution of ferrous sulphate, which forms, with the developer, an ink-like mixture. Here the print is toned black, the ground, however, at the same time, becoming dark violet; this, however, can be quite cleared off after the full period of development and treating with a 1 per cent. oxalic acid solution, which clears the ground. Any final deposit in the whites can be removed with Eau de Javelle.

The effect of other developers has been tried only to a very limited extent. It is found that a plain solution of diamidophenol in water develops the primary image to a colour approaching violet.

The process should certainly repay the attention of amateur workers. It is rapid, most inexpensive, and the results may certainly be considered as permanent; they have the character of prints in gum or carbon, but with the full rendering of the half-tones and great sharpness. Moreover, the process enables a great range of papers to be selected from.

DR. THIEBAU.

## Photo-Mechanical Notes.

### Flat Metal-framed Half-tone Screens.

A RECENT patent specification (No. 27,791, 1907) of Max Levy, of Philadelphia, describes the production of a screen for half-tone photo-mechanical work in which the edges are made of thinner substance than the main field of the screen, with the result that the whole screen can be given a metal frame which is flush with the glass on either side.

The frame, which in no instance exceeds the thickness of the two connected lined plates, is preferably made of metal, aluminium being suitable, and in each instance the frame has a groove to receive the reduced margin or tongue of the screen, the depth of the groove being such that the inner edges of the frame will be in line with the shoulders to hold the plates against movement should the cement between the plates become softened. The cement is placed either in the groove in the frame or upon the reduced margin of the screen before placing the frame upon the screen. The cement that is placed between the frame and the screen not only serves to connect the parts, but also forms a tight joint, and the flexibility of the cement allows for the difference in contraction and expansion between the glass and the metal.

The frame may be made up of one or more pieces of sheet metal which are bent in shape or connected to overlie the tongue or reduced margin of the screen, the corners of the frame being either mitred or square, and when the corners of the screen are removed the space in such instances will be filled with cement.

### PHOTO-MECHANICAL PATENTS.

The following patent has been applied for:—

PHOTO-ENGRAVING.—No. 18,775. Improvements in and relating to the preparation of surfaces suitable for photo-engraving. Arthur Payne, 31, Bedford Street, Strand, London.

A CONVENTION CANTERBURY PILGRIMAGE.—A few days ago a party, consisting of Mr. H. Snowden Ward (the president-elect), Mr. Walter Potter, and Mr. F. A. Bridge, set out for a pilgrimage. They did not start from the "Tabard" in Southwark, nor—as far as we can ascertain—did they have peas in their shoes, either boiled or raw. Their object was not to visit the dismantled shrine of Becket, but to make a tour of the neighbourhood of the cathedral city to prospect suitable places for the Convention excursions when the members assemble there in July next. The journey between London and Canterbury was made by the much maligned S.E. and C. Railway. On arrival the party was taken in hand by Mr. A. H. De'Ath for a three days' motor pilgrimage to some of the most interesting villages and towns in Kent. These included Patrichtown and Bekesbourne, Bridge, Littlebourne, Ickham, Wickham, Wingham, Fordwich, Sturry, Charing, Wye, Chilham, Faversham, Davington, Ospreng, Ashford, and the Surrey towns of Rye and Winchelsea. When the time comes for deciding upon the programme probably Rochester and Maidstone will be added to the above list, and the difficulty will be to know what to leave out, as many of the places mentioned have enough photographic material to occupy a considerable time, to say nothing of Canterbury itself.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between August 31 and September 12.

**CAMERAS.**—No. 18,265. Improvements in photographic cameras and stands for the same. Albert Nixon, trading as Camera Construction Co., and Owen Lindley, Eagle Works, Durham Grove, Hackney, London.

**CINEMATOGRAPHS.**—No. 18,428. Improvement in cinematograph optical lantern and similar apparatus. Thomas Daniel Ersser, 89, Friern Road, East Dulwich, London.

**ENLARGERS.**—No. 18,478. Improvements in photographic lantern enlarging apparatus. The Thorton-Pickard Manufacturing Co., Ltd., Arthur Gray Pickard, and Thomas Ripley Foxcroft, 6, Bank Street, Manchester.

**DEVELOPING APPARATUS.**—No. 18,570. Improved apparatus for developing photographic roll films in the strip where a dark-room is used. James Jerome McGhee, 65, South Side, Clapham Common, London.

**NEGATIVE CARRIERS.**—No. 18,640. Improvements in the negative carriers or holders of photographic enlarging and reducing cameras. George Lloyd Moore, 35, Temple Row, Birmingham.

**COLOUR SCREENS.**—No. 18,744. Improvements in or relating to the manufacture of screens for use in colour photography. Louis Dufay, 111, Hatton Garden, London.

**COLOUR SCREENS.**—No. 18,750. Improvements in and relating to the manufacture of grained screens for making colour photographs. Charles Louis Adrien Brasseur, 18, Southampton Buildings, London.

**DARK SLIDES.**—No. 18,769. Device for use in introducing plates into and removing them from photographic dark slides. Charles Wallace, 4, South Street, Finsbury, London.

**CINEMATOGRAPHS.**—No. 18,783. Life-motion-picture apparatus. Joseph Bianchi, 18, Southampton Buildings, London.

**CAMERAS.**—No. 18,920. Improvements in photographic cameras. Thomas Frederick Virgo, and Houghtons, Ltd., 88, High Holborn, London.

**SHUTTER.**—No. 18,922. Inside shutter for photographic cameras. Charles Henry Rott, 17, Orange Street, Swansea.

**PLATES.**—No. 18,987. Improvements in or connected with photographic plates or films and envelopes therefor. The Thornton-Pickard Manufacturing Co., Ltd., George Arthur Pickard and Robert Edwards, 6, Bank Street, Manchester.

**TRIPODS.**—No. 18,995. Improvements in camera stands. William Percy Wilcox, 60, Newhall Street, Birmingham.

**TRIPOD.**—No. 19,198. Improved photographic camera tripod. John Wilkinson and Alfred Wilkinson, 4, St. Ann's Square, Manchester.

**DAYLIGHT DEVELOPMENT.**—No. 19,218. Improvements in apparatus for use in developing photographic plates in daylight. Xavier de la Croix, 322, High Holborn, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**THREE-COLOUR CINEMATOGRAPHY.**—No. 7,514, 1908. The invention consists in the use of large aperture non-achromatic lenses for taking and reproducing records of colour in cinematographic projection. It is found that as in this method screens are used which absorb about two-thirds of the rays, the lenses used need not be corrected chromatically, as, by absorption of about two-thirds of the rays, the chromatic aberration is reduced to about one-third of its detrimental influence. The only thing required is that the individual pictures shall be of exactly equal size. This requirement is met by letting the focal distance of the individual lens-systems be of equal length for the fields of rays from which they are to produce pictures. As lens-systems capable of satisfying these conditions, such systems (for example as the so-called Herschel double lenses) are recognised, which consist of a bi-convex lens having a concavo-convex lens arranged immediately behind it.

Such lenses present only an insignificant spherical aberration, and form large aperture lenses, while the same are not chromatically corrected.

As the lens-systems used must, in order to obtain the correct proportions of perspective, and to avoid distortion, have a focal distance that is not too short, they also allow a large diameter of the lenses, with regard to their manner of action in other respects. A certain stereoscopic effect is unavoidable, because the different lenses must be arranged at the side of each other, and when the projection of the images is made, the individual composing pictures will, therefore, never cover each other with absolute accuracy but, for the purpose of restricting this effect as much as possible, it is necessary to arrange the axes of the lenses as close to each other as possible.

If three colour-screens are used, for instance a blue, a red, and a green one, the first mentioned, which requires the least amount of light during a given time of exposure, is suitably arranged in the middle, and the combination of lenses placed in front of this screen is provided with recesses or incisions in order to make room for the two other lenses. Ch. Peter Christensen, 13, Helgesvej, Copenhagen, Denmark.

**PROJECTION LIGHT VIEWING CHAMBER.**—No. 23,818, 1907. In connection with projection lanterns it is necessary to employ means for enabling the user to ascertain from time to time the condition of the source of light, and for this purpose it has been proposed among other devices, to suspend from an adjustable rod a box or chamber provided at its end nearest the source of light with a pin hole and at its outer end with a disc of ground glass or the like. The object of the invention is to modify this device so that it can be usefully employed in optical lanterns for cinematograph displays and the like. The box or chamber, provided with a pin hole, is mounted on the door, or, if desired, the opposite side of the lantern, in such manner as to be capable of being longitudinally adjusted and of being readily removed when required. George Robson, 21, Rochdale Road, Leyton, Essex.

**DARK ROOM SAFE LIGHTS.**—No. 8,368, 1908. The invention consists of light filter formed of suspended transparent particles, e.g. of lead chromate: 10 ccs. of a 10 per cent. solution of nitrate of lead are added to an aqueous hot 10 per cent. solution of gelatine, whereupon 10 ccs. of a 10 per cent. solution of lead chromate of potassium are poured drop by drop into the hot gelatinous solution of nitrate of lead which is continuously stirred. A yellow precipitate of very finely emulsified chromate of lead is thus formed. The excess of soluble salts is eliminated by washing in a similar manner as is done with the preparation of gelatine-plates. After washing, the non-actinic emulsion is heated in the waterbath at about 45 deg. C., filtered, and is then ready for use. The hot emulsion can be coated once or twice upon the surface of any suitable transparent material of convenient shape, size, and thickness. If the power of such screens has to be increased without sensibly affecting their luminosity, aqueous or alcoholic solutions of aniline—or methyl—(orange or violet methyl) colouring substances can be added to the solution either before or after solidification. When such substances are added after the screen has been finished, the screen has to be immersed in an aqueous or alcoholic solution of the colouring substances. If in certain cases it should be necessary to use considerable quantity of such colouring substances, the quantity of emulsified salts may be reduced in proportion. The non-actinic screens, made with absorbing salts as above, with or without addition of colouring matters, possess the same filtering properties as the coloured glass screens or paper screens used at present, but are infinitely more luminous than these latter. Xavier Jeannett and Emile Manvillum, 51, Rue Bonaparte, Paris.

**PRINT WASHERS.**—No. 27,680, 1907. This invention consists of a print washer designed to save storage and to facilitate exposure. To this end it is constructed in two parts, the one being a receptacle for the water and the other being a means of supplying the water.

The receptacle for the water is stamped out or made up of metal or any other suitable material in such a shape that it will nest inside the other. Along the edges near the top of such receptacles a series of holes is pierced to act as an overflow. The other portion consists of a clamping device to grip the

edges of the receptacle and to support a water delivery device in a suitable position, so that where it is attached to a water supply the water will be delivered in such a way as to cause the contents of the receptacle to revolve together with the prints.

Each part can be separated from the other in a moment, and each part will be interchangeable with corresponding new parts. By this arrangement a great saving of storage space is made without in any way sacrificing efficiency. W. Tylar, 41, High Street, Aston, Birmingham.

**CINEMATOGRAH MECHANISM.**—No. 563. 1908. The invention is of a safety shutter cut-off for the cinematograph projector for use both when the apparatus is stopped and when the film chances to break below the window. The system (magnetic) described, while able to cause the two required actions separately, causes the fall of the same shutter at the stoppage of the cinematograph and also when the band or film breaks or disappears; in case of severance or disappearance of the band the magnetic action is caused by the alteration of the tension of the band or its disappearance from the under part of the projecting apparatus, i.e., below the exposure window.

The apparatus necessary for bringing about the desired results are: 1, A shutter; 2, an electro magnet, these being the essential parts of the system; 3, a contact or automatic breaker to cause the obturation when the band breaks. The shutter may be placed at any convenient position relatively to the unrolling machine as will facilitate ready access to such machine, but is best placed near the condenser where the rays are not concentrated and give off but little heat, thus permitting the use of a material for the shutter which otherwise might be injured or spoiled; as the magnet may be constructed of any desired strength, the shutter may be of any weight, e.g., of unpolished glass. Thus, transparency, which is so necessary for the rapid and sure putting into position of the band or films, is an advantage added to the advantage of automatic falling. Eugène Louis, Amédée, Lertourné, 2c, Rue Pavée, Rouen.

The following complete specifications, etc., are open to public inspection before acceptance, under the Patents Act, 1901.

**LOUR SCREENS.**—No. 18,759. Manufacture of grained screens for making colour photographs. Brasseur.

**CINEMATOGRAHES.**—No. 18,783. Life-motion-picture apparatus. Bianchi.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### The Young Lady in the Reception Room.

Some few weeks ago (writes Mr. F. M. Sutcliffe in "The Amateur Photographer and Photographic News" for September 22) your professional contemporary had a series of papers on "The Young Lady in the Reception-Room," and showed how much she had to do with making or the marring of a business. It was shown how her hot and pushfulness increased the orders, and how her want of these qualities made business bad. Mention was made of the many qualities which go towards the making of an ideal receptionist—intelligence, gentleness, love, suffering, all the things St. Paul wrote but no note was made of that quality which womankind is supposed to be wanting in—namely, humour. That this virtue is not merely missing in the composition of the woman will be seen in the following extracts from my letter-book:—

"The Grand Hotel, Sandbay-by-the-Sea,

"August 2, 1908.

Mrs. Ponsonby Jones would like Mr. S—— to photograph her some morning when he is in a good temper and wide awake. Will be glad to know what time will be convenient."

Reply found in letter-book next morning:—"Mr. S—— is in a very good temper this morning and wide awake. He has no engagement for 11 a.m. to-day, if this hour will be convenient to Mrs. Ponsonby Jones, etc., etc."

**S. MENDELSSOHN, LTD.**—This old-established firm, conducted many years at Pembridge Crescent, London, W., has now transferred itself to new studios at 41, New Bond Street.

## New Apparatus, &c.

The Firelight Portrait Accessory. Sold by Marion and Co., Limited, 22 and 23, Soho Square, London, W.

Those who remember the article by Mr. Essenhigh Corke, which appeared last year in our issue of July 12, and described the methods of making firelight and lamplight effects in the studio by daylight, will be interested in hearing that an accessory which further facilitates this work has been placed upon the market by Messrs. Marion and Co. The apparatus is to enable the photographer to secure effects such as those by Mr. Corke also by daylight only and without any alteration or modification of the studio, so long as this building can provide a top light. In the method, as originally described by Mr. Corke, it is necessary to place the sitter upon a platform raised a foot or so from the ground, but by the modification which is now made all the work is done in the ordinary way on the floor of a studio, which has top-light, the only labour which the photographer

has to perform being the placing in position of the fireplace accessory, which also includes the background, and suitably posing his sitter. The illustration shows the accessory with a chair placed in position for the sitter, and we have before us a selection of prints showing the very charming and striking effects which are thus easily secured.

Those who turn back to the article which we have just referred to will find that the method advised for preparing the prints is either the bromide process, followed by the immersion of the print in a suitable yellow or orange dye, or carbon, using a transfer paper of suitable tint. However, the examples before us, which are almost equally effective, are made simply on P.O.P., and the photographer who takes up this form of photograph has the opportunity of giving to his results just as much warmth and vigour as the preferences of his sitters may render advisable. In other words, the depth of the dye or the colour of the transfer paper enables one to "turn on the firelight glow" to any extent. It will be found that it is easy to overdo it, but we can imagine that there are many classes of customer in whose eyes the somewhat overdone garish result is very likely to prove more acceptable than the less pronounced renderings which more truthfully reproduce a firelight lighting. The present season is an opportune one for photographers to interest themselves

in this special line, and it is not too much to say that a display of a few portraits made with the ease which is now afforded by the accessory should attract much attention in any town to the photographer's studio.

The accessory is sold by Messrs. Marion for 85s.; the oak chair shown in the illustration is 57s. 6d. extra.

The Isostigmat Anastigmat. Series I.  $f/4.5$ . Made by R. and J. Beck, Ltd., 68, Cornhill, E.C.

This is a new series of the Isostigmat, specially designed for the most rapid work. The lens we have tested is a No. 3 of focal length  $4\frac{1}{2}$  in., or, more exactly, 4.6 in., according to our measurements, and for a lens of such rapidity and cheapness its effects are somewhat striking. It gives a circle of illumination of  $5\frac{1}{2}$  in., and will therefore just cover a quarter-plate, though the hand camera to which it will be most perfectly suited will be one of the popular  $3\frac{1}{2}$  by  $2\frac{1}{2}$  size. At full aperture it gives extremely fine definition in the centre of the plate, while the falling-off towards the margins is very slight, much less than we expect to see with the ordinary R.R. lens working at  $f/8$ . For the sake of comparison, we tested this Series I. Isostigmat against a Series II.  $f/5.8$  lens, using the same aperture— $f/8$ —in both cases. As a general rule, an  $f/4.5$  lens need not be expected to perform quite so well at  $f/8$  as a lens of similar quality constructed to be used at  $f/5.8$ , but in this case there is very little difference. The circle covered by the Series I. lens is slightly smaller, and much more clearly defined at the margins. The marginal definition of the image is, however, very little inferior to that of the other, while the evenness of the illumination is as good, if not a shade better. In fact, the  $f/4.5$  lens, even at its full aperture, seems to give very satisfactory illumination. The most marked difference between the lenses is in the matter of depth, the new lens having distinctly less near depth and greater far depth than the older one when focussed on an object 8 ft. away. As has already been announced, this new lens will be sold on similar terms to the first Isostigmat during the month of September, the Series III. in plain iris mount being sold at £3 12s. 6d. during that period instead of at the full price of £4 15s. It is worth noting that a No. 2 of 3 in. focal length is included in the series; this is specially intended for cinematograph cameras.

**THE POCKET CINEMATOGRAPH.**—A very interesting novelty has been issued as a toy for children by the Kinema Novelty Co., 22, Gresham Road, Brixton, S.W., in the shape of a shilling packet titled as above, and procurable either direct or at the toy shops. The invention of Mr. Theodore Brown, it is a modified form of the Anaglyphs of Du Hauron, that is to say, advantage is taken of inks and filters of suitable absorptions to pick out separately two phases of some moving object, such as a game of see-saw. The two pictures are printed in red and green, and suitable eye-pieces supplied in a holder, which allows of one part being quickly interchanged with another. The result is most satisfactory in the cases of to-and-fro motion, and in one instance a very deceptive effect of rotation is imparted to a wheel. The shillingworth includes fourteen different subjects.

## New Materials, &c.

**Kodak Self-toning Glossy and Matte Collodion Paper.** Made by Kodak, Ltd., Clerkenwell Road, London, E.C.

This new introduction of the Kodak Company is worthy of attention, inasmuch as it provides the means of producing in a plain hypo bath prints of colder tones than are usually obtainable by this procedure, which in such cases is generally employed in conjunction with a salt bath. The directions, however, for the new Kodak papers run as follows:—

For gold, purple-brown tones, immerse the print without previous washing directly into the fixing bath for ten minutes.

For warm brown tones, wash the print in three changes of cold water, and transfer for ten minutes to the fixing bath.

For rich platinum black tones, put the print directly into the salt bath A, for three minutes, and then transfer to the fixing bath for ten minutes.

Washing.—Wash the prints for half an hour in a gentle stream of water.

Drying.—Place the prints between clean, dry blotters. If the prints are wanted quickly they may be dried by heat without harm.

The use of a salt bath, we find, gives a very close approximation to the results of platinum-toning of many self-toning papers, and the range of fine tones thus obtainable and the general richness of the effects should ensure a favourable reception for the new product.

**Christmas Cards for Photographs.** Sold by Marion and Co., Ltd., 22 and 25, Soho Square, London, W.

Messrs. Marion's 16-page list of Christmas mounts is the first to reach our table, and we have examined with much interest a number of the varieties of mounts for the festive season which it describes. The effective use which is made of air-brush decoration in a number of these mounts is noteworthy, and the method shows its capability of producing very effective colour effects, although perhaps the plainer and less adorned cards are really more effective for the presentation of photographs. Among these we like very much several folder cards in white and gold, such as numbers P. 31, P. 43 and P. 118. P. 31 takes a print  $4\frac{1}{2}$  x 3, and is sold at 2s. a dozen or 111s. per thousand. P. 43 is a double folder, the outside sheet having an oval opening  $3\frac{1}{2}$  x  $2\frac{1}{2}$ , bearing a very neat embossed design; with the exception of the brief wording "With Best Wishes" this card is innocent of the greeting or motto. It is made for a landscape print of 4 x 3 in., and costs 3s. a dozen or 171s. a thousand. A card of a similar

No. P. 21.

No. P. 141.

style, also of the single folder variety, and in white and gold, is No. P. 118, which is, however, of the slip-in pattern, taking a quarter-plate print, and costs 2s. 4d. a dozen, or 126s. a thousand.

A number of very neat little mounts of the folder variety for square or circle prints of small size are to be found in Messrs. Marion's selection. No. P. 89 is dark green with roughened edges and is for a print  $2\frac{1}{2}$  in. diameter to be mounted on, price 2s. 4d. per dozen, or 126s. per thousand. This is a double folder, the inside sheet being of ivory white. No. P. 128 is a light green or cream embossed pattern with a white slip-in mount, taking a print of  $1\frac{1}{2}$  in. diameter, and is sold at 1s. 4d. a dozen, or 78s. a thousand. A folder card for carte-de-visite prints, to be pasted on, is No. P. 21 as here illustrated. It is of cream board with a fancy border in pale green, a green seal, and with inside embossed line plate mark. For upright prints only it is sold at 2s. 10d. a dozen, or 153s. a thousand. Another tasteful card which we may illustrate is P. 141, of sage green with a white border containing a single white card inside, with a cut-out opening  $5\frac{1}{2}$  x  $3\frac{1}{4}$ ; this is sold at the same price as P. 118 above. The mounts thus particularised represent only a few of the large selection offered by Messrs. Marion, and an application to them for their full list may be recommended.

**CHRISTMAS MOTTO POSTCARDS**, obtainable in all the brands of Criterion paper (P.O.P., gas-light, and bromide), are being issued by the Birmingham Photographic Co., Ltd., Stechford, Birmingham, bearing inscriptions in an appropriately Dickensian vein.

**THE "RAJAR" CAMERA** offered monthly by Messrs. Rajar (190 Limited, Mobberley, Cheshire, for the best print on "Rajar" P.O.P. has been awarded to D. Abrahamse, 49, Chapel Street, Cape Town, S. A., his print having been judged the best during August. The paper on which the print was made was purchased from Messrs. E. Oakley and Co., Adderley Street, Cape Town, S. A.

# CATALOGUES AND TRADE NOTICES.

**A NOTABLE AMERICAN LIST.**—The full catalogue of photographic requisites issued by Messrs. George Murphy, of 57, East Ninth Street, New York, for the season 1908-1909 is a bulky volume of nearly 300 pages, and, as the title-page declares, is intended to list "desirable goods in use by the professional, amateur, mechanical and mercantile photographer." Its pages interest us greatly, for though many items, lenses chiefly, are European, the appliances of American origin, such as enlargers, shutters, tanks, troughs, dishes, stands, tripods, printing frames, etc., are, of course, built in almost every case with such obvious single end to efficiency in use that we rather congratulate the American photographer, handicapped though he is in other ways. Messrs. Murphy may take it from us that their list will interest all English-speaking photographers.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, SEPTEMBER 26.

Ch Middlesex Photographic Society. Outing to Chingford. C. A. Morgan.  
London and Provincial Photographic Association. Meeting, Franco-British Exhibition.  
Ch Suburban Photographic Society. Excursion to Chaldon and Upper Warlingham. J. Nixon.  
Ch Stereoscopic Society. General Meeting and Final Outing.  
Ch Sea Photographic Society. Outing to Low Street.  
Ch Sea Photo Art Club. Excursion to Black's Dam.

MONDAY, SEPTEMBER 28.

Ch London Photographic Society. "Bromoil." H. E. Gorfin.

TUESDAY, SEPTEMBER 29.

Ch Manchester Amateur Photographic Society. Lantern Lecture on Holland.

WEDNESDAY, SEPTEMBER 30.

Ch Camera Club. "Chemistry of the Production of the Photographic Image." A. Kirkland.  
Ch Camera Club. Supper and Smoking Concert at the Club Rooms.

THURSDAY, OCTOBER 1.

Ch Pool Amateur Photographic Association. "The Life and Times of Shakespeare." W. R. Yardley.  
Ch School of Photo-Engraving and Lithography. "The Selection of Photographs and Drawings for Illustrated Papers." A. Johnson.

**NOTTINGHAM CAMERA CLUB.**—Mr. Arthur Marshall presided over annual meeting of the Nottingham Camera Club, held at the Mechanics' Institution last week. The report, presented by the Secretary, Mr. S. W. B. Vines, stated that there were a hundred twenty-three members, against a hundred and twenty-five last year. The opinion was expressed that the last exhibition was the best ever organised by the club, but the committee stated that as some of the members would undertake the management at an exhibition next spring must be abandoned. Officers were appointed as follows:—President, Mr. Arthur Marshall; vice-presidents, Messrs. A. Black, W. S. Ellis, G. Hugo Hughes, J. Houston, W. H. Kirkland, W. Mosley, J. T. Radford, T. Wright; hon. treasurer, Mr. H. Roberts; reporter, Mr. G. Branch; lanternist, Mr. S. W. B. Vines; auditor, Mr. W. Vines; librarian, Mr. W. Goodchild; editor of journal, Mr. W. H. Radford; editor of portfolio, Mr. W. Murray; secretary, Mr. A. Gollard; curator of survey, Mr. J. T. Radford; committee, Messrs. A. Black, W. Darcy, W. S. Ellis, J. Gale, A. Hallam, Middleton, F. H. Radford, T. Wright, and R. A. Young; delegates to R. P. S., Messrs. A. Marshall and T. Wright; delegates to P. F., Messrs. A. Black, W. H. Kirkland, and T. Wright.

**POLYTECHNIC PHOTOGRAPHIC CLASSES.**—The winter session of the photographic School of the Regent Street Polytechnic will be held on Tuesday, October 13, by an exhibition of Autochromes, to which is free to the public. On that occasion information and advice may be obtained from the Principal, Mr. Howard Carter, and his colleague, Mr. C. H. Hewitt, as to the classes a learner may take with best advantage to himself. Those desiring to be present or to visit the Polytechnic personally are requested to apply for the full prospectus of the courses of instruction, which include every branch of professional and trade photography.

## Commercial & Legal Intelligence.

**A WARWICK BANKRUPTCY.**—The summary of the debtor's statement of affairs presented to creditors of Joseph Harriott, residing at 10, Chapel Street, Warwick, and carrying on business at 15, High Street, Warwick, showed gross liabilities amounting to £311 8s. 6d., of which £220 9s. 7d. was expected to rank for dividend. The assets, after deducting preferential claims, were estimated to produce £99 3s. 2d., leaving a deficiency of £121 6s. 5d. Bad trade and want of capital were the alleged causes of failure. The case, a summary one, was, at the first meeting of creditors, left in the hands of the Official Receiver.

**BRITISH PHOTO PAPER COMPANY, LTD. (London).**—Particulars of £5,000 debentures, created by resolution of November 6, 1907, have been filed pursuant to Section 10 (3) of the Companies Act, 1907, the amount of the present issue being £350. Property charged: The company's undertaking and property, present and future, including uncalled capital.

**EASTMAN KODAK COMPANY OF NEW JERSEY.**—The Eastman Kodak Company of New Jersey has declared an extra dividend of 2½ per cent. upon the common stock of the company, payable November 1, 1908, to stockholders of record at the close of business on September 30.

**CERIO PHOTO-PRINTING CO.**—A general meeting of the members of the Cerio Photo-Printing Company will be held at the offices of Gundry, Straus, and Soper, 7, Great Winchester Street, E.C., on October 27, for the purpose of having an account laid before them by the liquidator (Mr. Percy W. Straus) showing the manner in which the winding-up has been conducted.

**DISSOLUTION OF PARTNERSHIP.**—The partnership between Messrs. Abraham Srogov and Joel Halford, carrying on business as photographic enlargers at Birmingham, under the style of the Royal Art Association, has been dissolved by mutual consent, as from Sept. 7.

**A POSTCARD BANKRUPTCY.**—William Browne Barwell Barwell, of 12, King Edward Mansions, Shaftesbury Avenue, W.C., appeared for his public examination at the London Bankruptcy Court last week, before Mr. Registrar Hope, upon a statement of affairs showing liabilities amounting to £316, and assets nil. In reply to questions put by the Official Receiver, debtor stated that he was interested in a syndicate formed for the purpose of publishing picture postcards of famous pictures at the National Gallery. The petitioning creditor had advanced him money from time to time for the purposes of that business. They had to get the sanction of the authorities to take the photographs, but the matter had proved unfortunate, and they only had a few negatives. He made arrangements to get the negatives published in Germany. He had compromised the action brought by the petitioning creditor. He attributed his present failure to his liability to the petitioning creditor under a judgment obtained against him in respect of moneys advanced for the purposes of the syndicate referred to. The examination was ordered to be closed.

**SCARBOROUGH BANKRUPTCIES.**—At the offices of the Official Receiver, Scarborough, on Monday last, the first meeting of creditors was held in the case of Jordan Lambert Lilley, photographer, of 71, North Marine Road, Scarborough. The summary of debtor's statement of affairs showed gross liabilities amounting to £189 8s. 4d., of which £166 10s. 6d. is expected to rank for dividend. Furniture is valued at £25, and after deducting the amounts payable to preferential creditors, there is a deficiency of £164 8s. 4d. Debtor states his failure to be due to the illness of his wife during the past two years and three bad seasons.

The first meeting of the creditors of Mary Ann Osquith (widow), photographer, of Falconers' Road, Scarborough, was also held. The gross liabilities are set down at £105 3s. 10d., £83 8s. 8d. of which is expected to rank for dividend. The assets are estimated to produce £33 10s., and there is shown by the statement a deficiency of £71 13s. 10d. The causes of failure given are bad trade, owing to severe competition, and loss of £20 advanced in October, 1907, for commencement of a business at Frodingham, which, proving unsuccessful, was given up on January 1 last.

### NEW COMPANIES.

**KOSMOS PHOTOGRAPHICS, LTD.**—Capital £5,000, in 4,500 Preferred Ordinary shares of £1 each and 10,000 Deferred Ordinary shares of

1s. each. Objects: To carry on the business of photographers, photographic printers, chemists, manufacturers of photographic requisites, etc.

**HAMNETTS, LTD.**—Capital £1,000. To acquire the business carried on by T. Paddock, of 24, Lee Bank Road, Birmingham, and A. H. Taylor, at 197, Bristol Street, Birmingham, 3, Lichfield Street, Burton-on-Trent, and 6, Mercer's Row, Northampton, as Hamnett; at 58, New Street, and 10, Soho Hill, Birmingham, as Spencer; and at 82, New Street, Birmingham, as Rankin; and to carry on business of photographers and dealers in photographic materials.

## News and Notes.

**DARK-ROOMS AND THE FRANCHISE.**—Mr. W. H. Clay, revising barrister, commenced the annual revision of the voters' lists for the city of Gloucester at the Guildhall last week. Mr. W. H. Taylor, for the Conservatives, claimed votes for Mr. G. H. Neininger and his (Mr. Taylor's) brother in respect of the occupation of photographic dark-rooms. It appeared that neither Mr. Neininger nor Mr. Taylor were professional photographers. The former is an insurance agent, and lives with his father outside the city, but occupies a dark-room at his father's business premises in the city; whilst Mr. J. C. D. Taylor is a post office clerk, and the dark-room upon which he claimed is an attic at the Conservative agent's offices. Both claimants were "amateur" photographers, who asserted that they got their living partly out of their hobby by taking groups, etc. Mr. W. J. Arnold, for the Liberals, raised the objection that the premises referred to were not occupied by the claimants for the purpose of any trade, business, or profession. Occupation for the pursuit of a mere hobby could not qualify. He also submitted, in the case of Mr. J. C. D. Taylor, that the terms of his appointment as a post office clerk precluded him following any other business, but this Mr. W. H. Taylor contested. The Revising Barrister said, upon the facts, he ruled that the rooms in question were not occupied for the purpose of a trade, business, or profession, and disallowed the claims. He ruled similarly in regard to a claim in respect of dog-kennels in Barton Street, the claimant, Mr. Herbert Reginald Manwaring-White, not being a huntsman.

**LICENCES FOR TRAVELLING PHOTOGRAPHERS.**—Thomas Harvey was summoned recently at the Isle of Wight City Bench for having no pedlar's certificate. Defendant, with two assistants, was at Sandown on the 4th inst., taking photographs of houses, and when spoken to by a constable said he did not require a licence as he had nothing to sell. The constable said there were complaints last year from persons who were abused because they would not buy photographs. Defendant submitted that he was on the same footing as a commercial traveller, but the magistrates held otherwise. Supt. Galaway, D.C.C., said he did not wish to press the charge, only to stop the nuisance of persons like the defendant going on to premises uninvited. Defendant was fined 2s. 6d., and 9s. costs.

**CLASSES IN PHOTOGRAPHY.**—Courses of instruction are given this winter by Mr. E. Senior, at the Woolwich Polytechnic, on Wednesday evenings at 7, and at Battersea Polytechnic on Tuesdays and Thursdays. At the latter institute there are separate classes for elementary and advanced students respectively, as well as a special class in enlarging. Reduced fees are charged to students in the trade.

**THE FASHIONABLE CINEMATOGRAPE.**—The moving picture is becoming a serious rival to the after-dinner vocalist. Every Sunday evening at Prince's Restaurant (declares the "Daily Mail") a cinematograph show, which lasts about half an hour, is given. The diners now watch the realistic reproductions of topical events over their coffee and cigarettes, instead of listening to ballad vocalists, as heretofore.

**POSTTYPE PAPER.**—Mr. Charles Dawson writes us from Holloway Hill, Godalming, in reference to our recent notes on the process for direct positives, to the effect that he is only disposing of the European patents relating to the process. Since the appearance of our article he has been flooded with requests for prices and samples of the paper, but the present intimation, it is hoped, will correct any wrong impression that has been formed, and save those interested further trouble. In a previous issue we had stated Mr. Dawson's relation to the process.

**PROCESS INSTRUCTION AT MANCHESTER.**—The prospectus of the Photography and Printing Trades Department of the Manchester

Municipal School of Technology, directed by Mr. Charles W. Gamble, contains the syllabus of classes for the forthcoming session and as regards the purely printing side of the department is in itself a demonstration of the efficiency of the teaching staff, since its well arranged pages are composed and printed in the department. The photographic classes include two series of lecture demonstration each extending over 40 weeks and dealing respectively with the theory and practice of photography. Other more specialised classes held in the evenings, deal with negative making, the photography of coloured objects, portraiture, silver, carbon, and platinum printing, and retouching. The day and evening classes in photographic mechanical processes include lectures on the general principles of photo-mechanical and three-colour work and instruction classes in line-engraving, half-tone and three-colour block making, and lithography, in addition to subjects such as typography, bookbinding, etc. Those in the North of England able to visit the magnificent premises of the School and consult Mr. Gamble are advised by us to do so.

**THE HOVE CAMERA CLUB** exhibition will be held at the Hove Town Hall October 22-26. Entries close October 15. Mr. Furlley Lewis, F.R.P.S., will judge, and will have at his disposal for awards in the open classes for prints and lantern slides, ten specially designed Kupron-bronze statuettes. This is an entirely new departure, and should be acceptable to exhibitors. The statuette is reproduced on the entry forms, to be obtained from W. Chater Lea, Dyke Road, Avenue, Brighton.

**THE UNITED STEREOSCOPIC SOCIETY.**—Stereoscopic workers wishing to become members of the above society are invited to write to the hon. secretary on or before October 15, so that their applications may be entertained at the next committee meeting. The entrance fee is 1s., and an annual subscription of 2s. for members in the United Kingdom. The secretary is Mr. A. J. Snow, of 74, Lloyd Road, Walthamstow.

**SOUTHAMPTON CAMERA CLUB.**—The annual exhibition will be held at the Philharmonic Hall from October 13 to 17 inclusive. Mr. Arthur Marshall will judge the exhibits, the awards taking the form of silver flower vases, ten of which will be placed at his disposal for the open classes. Entries close October 6, by which date entry forms, duly filled up and accompanied by entrance fees, must be sent to the hon. secretary, Mr. S. G. Kimber, "Oakdene," Highfield, Southampton, from whom the forms are now obtainable. Exhibitors at Southampton who desire to enter their exhibits for the Hove and Portsmouth exhibitions, will be entitled to reduced fees and free conveyance between the three exhibitions.

**"OKRO" COMPETITION.**—The competition recently organised by Messrs. Rae, Ltd., of 147, High Street, Perth, in which prizes were awarded for prints toned with the firm's "Okro" toning solution, has been judged by Mr. Peat Millar, who reports that the uniformly good results (as regards tone) satisfied the efforts of the judge to base his decisions on this technical quality. The prints were therefore judged on their technical and pictorial merits, and the following awards made:—First prize, Robert Burnie, 86, Woodlands Road, Glasgow; second prize, George Anderson, 77, Braeside Street, Glasgow; third prize has gone to Peter Orr, 3, Alexandria Terrace, Govan. Other commendable work is that of George Madison, H. Black, A. J. Thistleton, D. L. Richards, Rev. E. T. Clark, and J. Lowrie.

**MESSRS. E. W. BOWES AND Co.,** printers and enlargers in platinum type, carbon, and bromide, advise us that they have removed to new and larger works, at 122, Becklow Road, Shepherd's Bush, London, W.

**PHOTOGRAPHIC INSTRUCTION IN LEEDS.**—The prospectus just issued of the Central Technical School, Cookridge Street, Leeds, contains particulars of the course of instruction in the theory and practice of photography under the direction of Mr. S. E. Bottomley, F.R.P.S. The lectures and demonstrations are given on Saturday morning from 9.30 to 12, and in each case consist of a lecture followed by practical work by the students. The fee for this course, which is specially intended for teachers, is two guineas, and the subjects include branches of photography such as photo-micrography, stereoscopic and cinematograph work, lantern-slide making, and the selection and use of apparatus. Evening classes of a more elementary kind are also included in the syllabus. Application in regard to these should be made to Mr. Bottomley, or to the principal of the school, Mr. R. E. Barnett, B.Sc.

## Correspondence.

\* We do not undertake responsibility for the opinions expressed by our correspondents.

\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

### THE SALON SELECTION COMMITTEE.

To the Editors.

Gentlemen.—It was with a not unnatural feeling of disappointment that I received some days ago the usual polite notice from the Photographic Salon informing me that the Committee had been unable to accept any of my works for exhibition. I was, however, quite prepared to believe that a committee composed of men having the aims and ideals which one always associates with the Linked Ring would not reject work unless they had a sound reason for doing so, and I felt that at least my work had had a fair chance, and had been found wanting, and that the only thing to do was to try again. I have since discovered that most of the other English contributors have been treated to a similar fate, being either rejected altogether, or represented very badly, whilst the Americans are in more than usual strength. This becomes very significant when I remember that five Americans were on the hanging committee, and still more significant is the fact that two of them are represented by thirty-nine and twenty-one works respectively. Another exhibitor closely associated with the hanging committee shows twenty-eight works, and with this addition the full committee of seven members are represented by a hundred and forty-two out of the total of two hundred and three in the catalogue. Of the other members of the Ring, English Links show only nineteen works, and English outside contributors show eighteen as against sixty-five last year. What at first sight looks like a rather sweeping condemnation of English work becomes on further investigation suspiciously like a pre-arranged monopoly. It is hardly conceivable that well-known photographers who have exhibited in the Salon for years would suddenly drop off in the quality of their work to such an extent that none of it was worth showing. It would seem that the selection committee have rejected as much outside work as possible in order to display their own efforts to better advantage, but if this sort of thing is to continue, the general contributor ought to know beforehand. He could then avoid the trouble and expense of submitting work to a committee having no intention of hanging it, and he might as a desirable alternative arrange with his fellow workers to run an exhibition which should fairly represent international pictorial photography, instead of vainly contriving to what is practically a three-man show. Messrs. Steichen, Roburn and De Meyer have already had an exhibition of their own. They are now having another at the expense of the Linked Ring, but the Ring is wise and intends to carry out its aims and ideals which, by the way, are not put forth in the catalogue this year), and will see to it that these gentlemen have run the show for the next time. It is one thing to run a "one-man show"; it is a very different matter to advertise a public one; and the Linked Ring must decide before next year which it intends to do, and give some proof in either case that it will do the thing thoroughly.—I am etc.,  
Park Row, Heaton, Bradford.  
September 16, 1908.

WILLIAM A. STEWART.

### A LAY REVIEW OF THE SALON!

To the Editors.

GENTLEMEN,—From among the quotations from the lay press on the Salon, you have omitted the following, evidently referring to the private view:—

"Americans continued the erratic course they have pursued recently, and after fluctuating violently in the afternoon finished back in the Street."

It is a cutting from the "Financial Times." Why it occurs under the heading "Stocks and Shares" is not apparent.—Yours truly,

"A CONSTANT READER."

### THE PICTORIAL WORK OF TO-DAY AND FIFTEEN YEARS AGO.

To the Editors.

Gentlemen,—May one be permitted to ask why it is that, in the current issue of your journal, the photographer whose negatives form the basis of the Raines and Co. exhibit in the South Room of the R.P.S. Exhibition is damned with the faint praise that his is perfect technical work, but that it serves to remind one "how far pictorial photography has advanced during the past few years?"

For my own part, as I looked at the exhibit, the reminder was of that of the work of Mr. G. R. Ballance. Possibly if Messrs. Raines were to do, as Mr. Ballance is said to have done by way of a practical joke, and that is, to print from the glass side of the negative on a piece of stale platinum paper, "the excellence of their work" would have been hailed with the acclamations of the pictorialist instead of being condescendingly passed on "to the professional photographer."

I am not a professional photographer, but I must confess that Mr. H. G. Ponting's masterly presentment of strong sunlight effects pleased me infinitely more than did many of the exhibits in the West Room, where sunshine generally seemed to be indicated by merely local rubbing down to white paper, leaving the rest of the picture in Stygian murk and gloom. And certainly I prefer them to Mr. Mortimer's "The Wool Washers," which, if it were not for the cast shadows, suggests to my mind nothing more than a November fog.

Both the mounting and the framing of the Raines exhibit seemed to me to be modern enough, so therefore I infer that the progress of modern photography is in the direction of dirty pigment and white paper as the best method of rendering vivid sunshine.

I venture to hope that I am not in a minority when I say that I prefer to lag behind if such be progress. So also, it seems to me, should the opticians and the plate and paper manufacturers. But perhaps the excellence of their products, like that of the work of Messrs. Raines, can be left to the appreciation of the professional photographer. Poor professional!

Trusting that some of your critics or some of your readers will be willing to enlighten me as to wherein the work of to-day shows so much progress, I beg to subscribe myself—Yours faithfully,

ANTI-PROGRESS.

### COPYING BLUE PRINTS.

To the Editors.

Gentlemen,—In No. 2520 of "B.J.," p. 651, "Printer" wants to know how to reproduce a blue print. The following suggestion may be useful to him:—

The original blue print may be toned blackish-brown by first bleaching it in a weak solution of potash or soda, washing thoroughly and then blackening in a solution of tannic or gallic acid and washing again.

This toned print may now be dried and used as a negative to reproduce on ferro-prussiate or fandyke solar (sepia) paper.—Yours,  
Ottawa, Canada,  
September 5, 1908.

C. O. S.

### PUBLIC EXHIBITION OF LUMIERE AUTOCHROMES.

To the Editors.

Gentlemen,—On the occasion of our opening night for the winter session (Tuesday, October 13) there will be an exhibition of Autochromes in the large hall of the Polytechnic, to which admission is free. The Autochromes will be shown on the screen in a gold frame setting, and every endeavour will be made to render the exhibition worthy of the process and its distinguished inventors. The members of the audience will be provided with cards on which to record their votes, and gold, silver, and bronze medals respectively will in this way be awarded. Landscapes, architecture, and genre pictures will alone be eligible. Full particulars and entry forms will be forwarded on application to—Yours faithfully,

ROBERT MITCHELL, Director of Education.

The Polytechnic, 309, Regent Street, W.

### FACTORS IN THE CALCULATION OF EXPOSURE.

To the Editors.

Gentlemen,—I wish to thank you for your excellent notice of my exposure indicator in your issue for September 4. It is extremely

gratifying to me to have had such good notices for my first effort at placing upon the market a piece of photographic apparatus, especially from the "B.J.," which I have always looked upon as the most technical and the most critical of the photographic press. This is a genuine attempt to simplify some of the problems which constantly face the all-round worker. The actinometer, as at present used, does not give the same relative sensitiveness to varying strengths of light as the plates, hence the necessity of making some provision for increased exposure in poor light. Then the proved inefficiency of the lens shutter as compared with the focal-plane shutter, added to the increased efficiency of the modern anastigmat, enabled me to evolve my lens and shutter factors which in practice have proved very valuable. As to how much belongs to the lens I am not prepared to state, but the fact remains that many of the modern large-aperture lenses give a fuller exposure, stop for stop, than the older types. One reason for this I suggested in an article in "The Process Year-Book" on page 110, 1907-8. This illustration was given me by one of our leading opticians, and last winter, when discussing the same question in the show-room of one of the principal London lens-makers, the manager agreed with me that the difference could exist and would be principally in marginal illumination, but he also said that the modern optical glasses had a considerable influence in this direction. Messrs. Beck are advertising their Isostigmat as the fastest lens, stop for stop, on the market. This still further tends to confirm my conclusions with regard to variations in speed. I have spent a large amount of time trying to formulate these differences, but as different types of lenses have varying properties it has always eluded me. Therefore I have preferred to state the fact vaguely and lump it all together with the light and the shutters and leave the rest to the intelligence of the photographer, who must decide for himself whether his lenses are rapid or slow. The question of telephoto exposures has been occupying my attention of late, and I hope to have something to say thereon at a future date. Meanwhile, allow me to remain, yours faithfully,

E. A. BIERMANN.

Arthur Cox Illustrating Company, Birmingham.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 2A, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 2A, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 2A, Wellington Street Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

- J. Yeoman, Bedale, Yorkshire. Photograph of the Bedale Cricket Club.
- A. Kent, 361, High Street, Rochester, Kent. "Try and Get it."
- J. & W. Cooper, 32, High Street, Wealdstone, Middlesex. Photograph of Mr. and Mrs. Gales.
- W. Marshall, 31, Hart Street, Henley-on-Thames. Photograph of the new Congregational Chapel, Henley-on-Thames.
- J. H. Jones, 8, Snowden Street, Port Dinorwic, North Wales. Photograph of "Moriah" Congregational Chapel, Port Dinorwic.
- S. A. Chandler & Co., The Arcade Studio, Exeter. Photograph of the Exeter City Football Team, Season 1908-9.
- F. Spivey, Landseer Studio, High Bridge, Howden, East Yorks. Photograph of Howden Church. Photograph of Entrance to Saltmarsh Park.
- J. Brooks, Coal Clough Lane, Burnley. Photograph of Sam Moss.
- E. Kelley, 26, Queen Street, Newton Abbot, Devonshire. Photograph of Mrs. Morrison Bell.
- H. Marshall, Waterlooville, Cosham, Hants. Photograph of Monument outside the Bat and Ball Inn, Hamledon, with Jessop, Fry, Sprot, and Tucker on it.

### PAINTINGS REGISTERED:—

- R. Elliott, 135, Rotton Park Road, Birmingham. "Four Water-Colour Paintings: St. Anthony, Sacred Heart, St. Patrick, and St. Joseph."

- IVORY MINIATURES.—1. Please tell me where to obtain ivory suitable for carbon miniatures? 2. What preparation does it require? 3. Would "ozobrome" be as good as ordinary carbon for same? 4.

What colours to use in painting miniatures, and where obtained?—IVORY.

- 1. It is supplied by all artists' colourmen. 2. It is sold ready for painting upon. 3. We have not tried it, but it is possible that the ozobrome solution would stain the ivory in such a way that the picture would be useless for after-colouring. 4. Ordinary water colours, either cake or tube, as sold by all dealers in artists' materials.
- H. AND G.—1. The lights are arranged in front of a semi-spherical or umbrella-shaped reflector which is painted dead white. 2. At least 8 or 12 burners are necessary. 3. The most rapid you can obtain. It is not easy to give too much exposure in this class of portraiture.
- J. A. C.—1 and 2. We are sorry, but we cannot obtain any information as to the firms. 3. We know of none, but the matter is out of our province. We advise you to address a stationery trades journal.

- E. A. R.—No, 7 inch is none too long for a postcard-size plate, but about right. You cannot do better than select the focus and aperture you name. Anything much larger than  $f/5.8$  is not of much use for average work, even with a reflex.

OIL COLOURING.—Will you inform me whether one can obtain transparent thin oil colours specially made for painting enlargements in oils, so that the modelling of the print will shine through the paint? I have hitherto painted all my enlargements in ordinary oils, but I am certain there is an easier method, if I could only obtain the proper paints.—ARGO.

We know of no such special colours being made for colouring enlargements in oils. Transparent colours (water) are supplied by all dealers for tinting photographs. Here in this country, ordinary oil colours are used for enlargements.

THE LORD'S DAY OBSERVANCE ACT.—I have been obliged to county court a man for the balance of an account for photographing his house and grounds. The work was done on Sunday at his own request. Would it be possible for the defendant to set up a statutory defence under the Lord's Day Observance Act? We do not make a practice of opening or working on Sunday.—H. C. L.

According to the Act, payment cannot be recovered for work done on the Sabbath, unless that work was one of necessity, which, of course, photography is not. If your debtor was mean enough to set up the old Act of Charles II. as a defence it would no doubt succeed. But it has been decided that if the debt has subsequently been admitted it can be recovered. From your letter it seems that a part of it has been paid, and that is an admission of the indebtedness, so we think it will be of little use for the debtor to plead the old Act as a defence.

METOL.—I do a lot of bromide developing with metol, and though I am very careful to wash my hands in very hot water I have a very numbed feeling in my hands. Would this be caused by the metol developer? If so, would you mind giving me a remedy?—H. A. S.

It is possible. Persons vary very greatly as regards susceptibility to metol. If you find you are likely to be a sufferer your best course is to avoid its use altogether.

STAINS FOR FRAMES.—Will you please give me instructions for making, and the best method of applying, light, medium, and dark brown and green stains for staining oak picture frame moulding, something that will dry with a matt surface and not obliterate the grain of the wood preferred?—MITRE.

The following stains are taken from "Figures, Facts, and Formulae": Brown stain for oak:—(a) Potass. bichromate, 1 oz.; water, 20 oz. Or (b) potass bichromate, 1 oz.; Vandyke brown, 4 oz.; strong ammonia, 20 oz. Or (c) catechu, 4 oz.; water, 100 oz. Boil, and add sodium carbonate, 1 oz. Green: A. verdigris, 4 oz.; vinegar, 40 oz.; B. indigo, 4 drams; vinegar, 20 oz. Boil each for ten minutes. Mix according to tint. Average proportion: A, 6 oz.; B, 1 oz. It would save you trouble if you were to buy the stains, such as Stephen's wood stains, which are to be had in a great variety of tints or colours at most oil shops. The frames must be made perfectly smooth, with fine glass-paper before the stain is applied.

FLASHLIGHT PHOTOGRAPHS OF BURGLARS.—I propose to obtain a flashlight picture of certain nocturnal thieves, and the better to effect this purpose should like to employ a "truc," an electric "truc" which I have occasionally seen at fairs, etc. The spectator is invited to grasp a handle of metal, and, having done so, finds he is no longer able to relax the grasp and withdraw his fingers, not-

withstanding his will to do so. Could not this be managed by connecting the current to a lock, which would transmit it to false key, pick-lock, etc., or to a balustrade, etc.? What kind of battery should I employ, and how many elements to produce a certain effect desired? Would the cost be high? Would the contact of the electrodes with the two hands be indispensable?—**PHOTOPHIL.** If a metal plate is so arranged that anybody desiring to tamper with the door must stand on it, and if a powerful faradic coil is connected with one terminal to the lock and the other one to the fore-mentioned plate, anybody making connection by means of a key or other instrument to the lock will receive a powerful shock, but only on the following conditions:—Should their feet, which are in contact with the metal plate, be well insulated, it will be impossible for current to pass, and they will not receive a shock. The question as to whether the person receiving the shock is able to leave or not is a difficult one to answer, since some individuals are much more sensitive than others, and, moreover, a shock so powerful as to prevent all movement is likely to be dangerous to the person receiving it. A coil which would be required to work the night through and year after year would require to be of the best possible construction and protected from damp, and arranged that the humming noise which it gives out when working is entirely done away with by enclosing it in a felt-lined box. The cost, complete with batteries and connections, would be approximately, £5. If it is only intended to use the instrument occasionally the cost of the coil itself would possibly be somewhat less.

**LOWED PRINTS.**—Could you tell me the cause of the enclosed prints turning yellow? It is gaslight paper, developed with metol-droquinone developer, and fixed in hypo and chrome alum, and used 30 drops of 10 per cent. metabisulphite of potassium. I develop about fifty prints and fix. The stains do not appear until the prints have been washed one hour. Then the backs and the edges turn yellow, like enclosed prints. If you could advise me how to stop this I should be greatly obliged.—**SPECIALIST.** Stale developer and stale hypo solution are common causes of stains in gaslight prints. In your case we expect that the individual prints are suffering owing to your treating too many at one time. It would be better to wash in several changes of water rather than use running water for an hour.

**LOWED P.O.P.**—We are troubled occasionally with a tingeing yellow in our P.O.P. prints, more discernible in vignettes. The edges of two oval-cut vignettes show a deeper yellow. I blame the prints, through lying between toning and fixing, although we are running water on them during toning and fixing operations. There are any known cause, and what is the remedy? Our rivers are often flooded, and we use it, with a muslin cloth on.—**ABSON.**

You do not give sufficient details to enable us to suggest any special cause, but if you leave the prints long between toning and fixing stains are very probable.

**ERN SLIDE QUERIES.**—Will you tell me, through your valuable paper, where I am wrong? I have been trying to make some lantern slides by the albumen process, but failed at start. I did not have articles of Mr. Foxlee, so I bought some collodion, after which I dissolved 6 grains ammonium iodide in  $\frac{1}{4}$  oz. of alcohol, put this to 1 oz. of collodion, and I should think it was near three months before I used it, when it was quite a dark colour. The slide was well corked and was kept in dark. After I had put a coat of albumen on the slide, made with one egg, one quart of water, and a few drops of ammonia, I poured over plate some of the collodion, which was quite clear, but I had trouble in getting it to travel to the edges; it seemed to get stiff. But the worst trouble was when it dried—a muddy yellow colour, full of lumps and fantastic shapes. Of course, I am only an amateur, I am fond of trying most everything. Do you think the carbon process best, or which, in your opinion, do you think the best—mean the nicest—printing process? I cannot get the whites clear with the carbon. I hope you will answer, if it is not too far away, my questions.—**INQUISITIVE** (Valley Field, Canada).

It is very clear that the collodion you employed was quite unsuitable for this process. Possibly you used enamel collodion, which is quite useless. What should be used is the collodion made for lantern slides. Not having read the articles you refer to it is evident

that you are "all at sea" with regard to the method of working, for we assume from your letter that the collodion was allowed to dry. That should not be. When it has set, the plate is put into water, and the ether and alcohol washed away. Then, after draining a little, the *iodised* albumen is applied and the film allowed to dry. When dry, it is ready for sensitising in the silver bath. The carbon process yields excellent lantern slides, but, on the whole, we prefer albumen, though the working of this latter process involves more trouble than the former.

**SKETCH PHOTOGRAPHS, ETC.**—(1) I saw some time ago, in a photographer's window at Cheltenham, a set of prints resembling black and white sketches, slightly tinted. I should be glad if you can tell me the process, as I am desirous of making some similar. I have an idea that the process was given some time ago in the "Journal," but as I do not file them I cannot trace it. (2) Is it advisable to use alum in the hypo fixing bath for P.O.P. prints, as by so doing it saves, to a certain extent, the labour of a separate hardening bath?—**R. O. JONES.**

(1) We do not recognise any recent article from your description, and we fear we cannot usefully make any suggestion in the absence of a specimen of the process. (2) Certainly, an alum hardening fixing bath may be used, but in the case of P.O.P. a separate alum bath is really the safer plan, since an overworked alum-hypo bath is liable to give rise to sulphur compounds, which may affect the permanence of the prints.

**DUTY ON PHOTOGRAPHIC OUTFIT.**—I am sailing for Australia next month and purpose taking a few dozen photographic plates, camera, and several Ross's and other lenses, all been used (except plates). Will you kindly inform me if I shall have to pay duty on any of the above articles?—**WM. H. TURNER.**

We believe that an outfit (personal equipment) such as you describe will not be dutiable.

**PURCHASE OF OLD NEGATIVES.**—Having a lot of waste negatives can you tell me of any firm that buys them up? Had some one call on me, but have lost his card. Perhaps you could give me some information.—**PYRO.**

A firm of the name of Bowen formerly advertised its readiness to purchase, but we have no recent address of it.

**LOSS OF NEGATIVE.**—Will you kindly inform me what remedy I have against a certain firm of enlargers, to whom I entrusted a negative for an enlargement and who have lost the same? It is now three weeks ago, and I am unable to get anything definite from them. All they say is that they are making search for the negative, and as soon as it is found the order will be executed.—**ANXIOUS.**

The only thing you can do is to sue the firm in the County Court for the value of the negative, and possibly for damages for its retention. If you write the parties to the effect that you will take immediate proceedings it will possibly cause them to make a more diligent search for the negative than they have previously done.

**A. GATES AND SONS.**—We cannot trace an advertiser of this particular line. We advise you to apply to the Aerograph Company, 43, Holborn Viaduct, for a reference to a firm, or you might get into touch with firms by a small announcement in the "Miscellaneous" advertisements.

**PHOTOGRAPHS ON WOOD BLOCKS.**—Could you inform me of a simple formula for photographing upon box-wood for engraving? If this is a trade secret I should be glad if you could tell me of a suitable white paint I could procure or make which would be suitable for coating the surface of a wood block, preparatory to sensitising it with silver or other emulsions. The white required would have to be put upon the surface thinly and evenly, and to withstand the action of water.—**A. J. HOWE.**

Those who make photographs on wood blocks for engravers treat the details of the methods they employ somewhat as trade secrets. One method we know is the carbon process, with a special tissue made with a very poor and soluble gelatine. This tissue contains a large proportion of pigment in proportion to the gelatine, so as to get a thin film that does not split up under the graver. We believe some employ an iron process, similar to that of the sepia paper process. The white ground is obtained by rubbing zinc white, moistened with water, well into the grain of the wood. The Autotype Company will probably make you a suitable tissue for the purpose.

**PYRAMIDOL DEVELOPER.**—In your issue of June 12 last you gave a

developer for plates, and if my memory serves me right it was not in your "Answers" column, of which the following was the copy I made at the time:—Pyramidol, 15 grs.; soda sulphite, 160 grs.; potass carbonate, 160 grs.; water, 7 oz. But I cannot procure pyramidol anywhere, and no one knows it. Did I mis-copy and ought it to have been pyramidon?—G. R.

You are correct. Pyramidol is the name of the developer, which, so far as we know, is not at present marketed in this country. The makers are the Brugg Chemical Works, Brugg, Argovie, Switzerland, from whom, doubtless, you could obtain a small sample of the substance.

**MATERIAL FOR STOPS.**—Kindly inform me where I can obtain a small quantity of thin vulcanite or celluloid suitable for making Waterhouse diaphragms for a large lens?—P. D. PRIOR.

Thin vulcanite may be had from Messrs. F. Hill and Co., 108, Bishopsgate Street Within, E.C.; celluloid from the British Xylonite Company, High Street, Homerton. We are not sure that either firm supplies such small quantities as you will require for a few stops. You will, we expect, have to take the full size sheet. Really your best course is to go to an optician for the work.

**IMPROPER USE OF CUSTOMERS' NEGATIVES.**—Will you kindly let me know if an enlarger has the right to make specimens for himself from negatives given him to make enlargements from, and, if not, what proceedings or steps could be taken to prevent him? as I have been repeatedly annoyed in this direction for some time.—R. HERMAN.

No, certainly he has not. No respectable firm would think of doing such a thing without the customer's permission. To put a stop to this sort of thing you should place the matter in your solicitor's hands.

**BLOOM ON ENLARGEMENT.**—The enlargement was made about twelve months ago; I have washed a lot of the working-up off. Can you inform me what is the cause of the bluish bloom that is seen in all the shadows? They were not there when it was sent away from here.—W.

We should say the cause is sulphur toning, probably arising from insufficient washing, coupled with hurried fixation. The maker of the print should be able to judge if this is so. The formation would not appear for some time.

**COATING WITH CELLULOID.**—Can you suggest how to prevent smudges and air bells when surfacing miniatures with celluloid similar to the enclosed photographs. I clean prints carefully before soaking with spirit, also the celluloid. I have used both methylated and alcohol, but I get very uncertain results. I get, perhaps, a dozen or so right; and then, without any apparent cause, they get smudgy. Has it to do with the pressure of roller not being heavy enough? After placing print in contact with celluloid I blot off superfluous spirit before putting under roller. Is this right? Should be greatly obliged if you can suggest a remedy or point out a fault, as the percentage of waste I get is a great loss of time, especially as I am expecting to get busy in the near future.—B. B.

Since you get a dozen all right at times and then some wrong, it is clear that the trouble is due to something in the manipulation. By close observation you should be able to detect what that is better than anyone else not seeing the work done. The only suggestion we can make is that the spirit is possibly blotted off too closely in some instances. Of course, you know that the celluloid should not be soaked in the spirit.

**JUSTICE.**—It seems to us that the only thing you can do is to sue for the money in the county court, according to the terms of the agreement, whatever they may be. The solicitor who acted for you in the dissolution of the partnership might help you, however. You say that the man is poor, has a large family, and that the business is very bad; that is probably the reason why he is unable to keep up the monthly payments. As he has had to give a bill of sale on his effects, you should consider whether it would be really advantageous to institute legal proceedings. We think your strictures on Freemasons are quite unwarranted. Yours is not a case that the P.P.A. could well deal with.

**W. G.**—We cannot say at the moment, but will make inquiry.

**FADED PRINTS.**—I have a number of albumenised paper silver prints, reproductions of pictures, which are very much faded. Unfortunately, they cannot be replaced. Is there any way of

restoring them satisfactorily? I fancy they have been made with dextrine.—THOS. HUSON.

There is no really satisfactory method. The best plan copy the prints, in which process a good deal of improvement usually be effected.

**RESIDUES.**—(1) Having a quantity of residue thrown down with of sulphur, I should esteem it a favour if you could let me the method of getting it down to the metal. I have a furnace which I could use if necessary, as I wish to ascertain whether I receive my correct value; (2) also if there is any method of throwing down or extracting the silver from the hypo bath than liver of sulphur.—L. W.

(1) The residue must be well dried and then mixed with equal weight of a mixture of equal parts of carbonate of potash and carbonate of soda. It is then put into a Cornish crucible then placed in the furnace, and submitted for a time to a red heat until it is reduced to the metallic state. The operation must not be hurried, as it will take some time. It may, however, be somewhat hastened at the later stage by now and then dropping a small crystal of nitrate of potash in the crucible. (2) No. 1 is the simplest and best method.

**THE AFFILIATION OF PHOTOGRAPHIC SOCIETIES** held their annual gathering at the Royal Photographic Society's Exhibition at the Gallery, on Friday evening last, September 18. There was a full attendance, nearly 400 Affiliation members and their friends present, a representation of forty-nine societies. The meeting, took place in the North Room, was presided over by Mr. P. Rider, the chairman of the Executive Committee. He welcomed members of the Affiliated societies on behalf of the Executive Committee, and in the course of a short address reviewed the work of the Affiliation for the past year, mentioning that the committee added several new lectures to those available for circulation referred to the extended scope of the "Red Book," under the auspices of Dr. A. R. F. Evershed. He also spoke on the new Cornish scheme which has now been well started. The London districts have been mapped out into certain areas, and the scheme has been generally taken up by the various societies. He stated that the matter of reduced railway fares for photographers has been under consideration, but that no definite arrangement has yet been made with the railway companies.

The chairman impressed upon all societies the importance of cultivating a spirit of mutual friendliness, and expressed the hope that members of one society would welcome members of another society at their meetings so far as this was possible.

The 1903 set of competition slides were shown on the screen, and the critical notes by that well-known authority, Mr. W. R. B. of Derby, were read by Mr. W. Davenport.

The vote of thanks to the Royal Photographic Society for granting the use of the Gallery on this occasion was proposed by Mr. J. Bridges, seconded by Mr. E. Human, and heartily carried. Human took advantage of the opportunity to give some details of particulars regarding the "congress" of photographers, to be held at the Franco-British Exhibition on September 26. The meeting was a thoroughly enjoyable one, and shows that the gathering grows popularly each year.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received by the publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

An exhibition of multi-colour pictures by the brothers Hofmeister their friend H. W. Müller is now open at the house of the British Journal." Mr. F. C. Tilney gives his impressions of pictures, and Herr Ernst Juhl, of Hamburg, contributes some on the remarkable work of these German pictorialists. (P. 752.) Salon des Refusés, consisting of works which were not selected by the Americans at the recent Salon, are being shown by our temporary, "The Amateur Photographer," at 52, Long Acre. (P. 753.) The remainder of the historical review by Mr. H. J. Channon phenomena of reversal, etc., by light appears on page 756. A full specification of the ferric-ink process for the copying of Mr. H. L. Shawcross is given under Patent News on page 758. The "great congress" of photographers at the Franco-British exhibition took place on Saturday last. (P. 758.) C. E. K. Mees continues the article on the principles of photographing coloured objects. (P. 754.) The making of combination group negatives by the use of hydrocyanic acid is the subject of some editorial notes on page 751.

## "COLOUR PHOTOGRAPHY" SUPPLEMENT.

Alfred Watkins gives details of the method found advisable for the making of Autochromes, namely, exact exposure varied by time development. (P. 73.) Some practical notes on carrying out the new Lumière method of development are given on page 79. Among the Autochrome items of the month are the recommendations of one French worker to use ammonium carbonate in place of ammonia when on tour, to use a white backing card when necessary and to re-develop the reversed plate after a convenient period; another, to employ a blue screen when viewing Autochromes artificially light. (P. 75.) The conclusion of the paper by Dr. E. Stenger and Herr F. Channon on the preparation of copies of screen-plate transparencies aims the rules for exposure of screen-plates of geometrical form to several sources of light. (P. 76.) A German worker has pointed out the practicability of using the Autochrome plate for combining three different pictures in a single transparency. Each is seen separately by employing a blue screen. (P. 80.) H. G. Drake-Brockman communicates the results of his experiments of the development of Autochromes by orange light. (P. 80.)

## EX CATHEDRA.

### Free Enlargements Again.

A few days ago at our private address we had the unexpected but highly appreciated honour of a visit from a gentleman who expressed himself as anxious to present us with a finely finished enlargement from any portrait that we would lend to him for the purpose. The presentation was to be quite free of charge, and only one condition was proposed—namely, that we should hang up the result in some position where our friends could see it, and that we should explain to them that the same gentleman would be very pleased to supply them with similar fine works of art at the price of one guinea. Very unfortunately we were not at home at the time; which circumstance we shall never cease to regret if such an opportunity does not occur again. Some of our readers who happen to live in Greater London may, however, be more fortunate, and if they do make the acquaintance of this philanthropist, we trust they will not fail to draw his attention to the fact that we, not desirous of being outdone in deeds of generosity, have given him this advertisement quite free of all charge. We have not ourselves seen the gentleman, but he has been described to us as stylishly dressed and prepossessing in appearance. Curiously enough, his visit to us was preceded by one from a lady making inquiries after some mysterious sample enlargements supposed to have been left for inspection. This may have been a coincidence or it may not, but samples did arrive later with the gentleman of prepossessing appearance.

### Relief In Lantern Slides.

Autochrome lantern slides, which are much in evidence just now at the exhibition of the R.P.S. at the New Gallery, very frequently show an almost startling effect of relief on the screen, and a similar appearance is also very often observable with colour slides made by the Sanger-Shepherd and other processes. Monochrome slides give the effect only sometimes, and it will generally be most often observed in the slides of some particular worker. At one lecture it may be so striking as to give rise to comments among the audience, while at another lecture given by some one else not a single slide may show it. We have frequently been asked to explain this effect, which the average man wrongly describes as "stereoscopic," and the fact that it is so common with colour slides and so uncommon with monochrome images suggests a very sufficient reason. It is simply because the colour slides are truer in their representation of distance than the monochrome slides, or, in other words, because they give truer perspective. Truth of outline is not sufficient in itself to give true perspective. Colours and colour values also play a most important part, and if they happen to be false the effect of solidity or distance vanishes even though the

linear perspective is true. In a colour slide there is no translation of colour into monochrome, and therefore if the colours themselves are truly represented and correctly graded the perspective should be true. On the other hand, in a monochrome slide, in spite of all the glib talk we hear with regard to colour values, colours are often wrongly translated, and the perspective is upset. Some careful workers avoid this blunder, but others take no precautions, while many are quite unable to distinguish between true and false values, and their slides as a consequence are untrue in their perspective, and fail to give realistic relief. It is quite easy to go wrong in the colour perspective in a colour slide, but the faults are more obvious, and it is much easier to obtain correct results than in monochrome work. Therefore colour slides, as a rule, show more relief than ordinary slides. Few people realise the amount of apparent relief that can be produced as the result of true perspective alone, and quite independently of binocular vision.

### Some Advantages of the Stereoscope.

In a set of stereoscopic slides recently submitted to us for inspection we noted a striking number of instances in which the value of the stereoscopic camera was demonstrated. The vast majority of the photographs are made for the purpose of recording facts, not for pictorial purposes, but the average single lens photograph often fails most lamentably in the truth of its records. Sometimes this is due to bad photography, or to wrong values, but often it is due to the fact that the subject does not fully reveal its details when viewed from one point only. To give a few instances from the slides mentioned. When examined as a single photograph one showed a man sitting on a rock, and only very close inspection revealed the fact that there was something peculiar in his attitude. The stereoscope instantly cleared up the mystery by showing that he was not on that rock at all, but on another a fairly long distance away. In another slide a group is observed sitting at what appears to be the entrance to a shady cave, at the back of which water is falling. In the stereoscope it is instantly apparent that they are sitting at the brink of a chasm at the further side of which there is a considerable waterfall. Considered merely as a view of a certain piece of natural scenery this photograph is a complete failure when viewed monocularly, but in the stereoscope it is a distinct success. Yet again, in a view of a mill an unbroken sheet of water falling from an overflow might equally well represent a sheet of some opaque fabric until we bring the stereoscope into play. Then we not only see the gleam of the falling water, but find the sheet is so

transparent that we can see the details of the mass behind it right through the water. These are only a few examples of the detail-revealing properties of the stereoscope, but they should be sufficient to show that the stereoscopic camera is an instrument of very material value even to the tourist who only collects holiday records.

### Lightning Flashes.

Photographs of lightning often have a very deceptive effect, owing to the fact that they do not readily reveal the direction taken by the flash. The details of a lightning flash are unfamiliar to us, and we cannot study them outside a photograph, and many of the peculiarities observed in the photograph are most certainly simple effects of perspective, it is difficult to correctly interpret them owing to our want of familiarity with the natural objects. Small bright sparks or bulbs in the flash are generally considered to indicate that at these points the flash is travelling either to or from the observer, but whether to or from it is almost impossible to determine. In many cases the flashes look like vertical ones passing from the clouds directly to the earth, whereas they were really discharges from cloud to cloud and nearly horizontal. It seems to us to be a great pity that such lightning records are not made stereoscopically, as the binocular records would quickly reveal many particulars that we can only guess at from single photographs. For distant flashes the ordinary stereoscopic camera would, of course, be of much use, as the separation of the lenses would be too small, but two similar cameras used together with a separation of several feet should give very interesting results.

### Black Background.

An inquiry from a reader who asked how to paint a dead black ground in distemper suggests the use of which a really black ground is in the hands of a man who knows how to use it. When taking a subject in a white dress against a dark ground, if the plate is really well exposed a ground of deep grey colour will print practically black, but any error on the side of over exposure will make an apparently black distemper ground appear a shade or two above absolute black in print. There is not nearly so great a desire for the absolute black ground as there was a year or two ago, yet they are still used considerably, and of course when well handled the proper subjects are very effective. It may therefore be of interest to give two methods of achieving the desired result. One method is to cover an ordinary stretcher with black art serge and use the ground diagonally from the light. The texture of the serge absorbs all light and reflects none, whilst the join which must be made for

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1909.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-eighth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of over 1,000 pages, and the entire edition of 25,000 copies was sold out immediately. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1909 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

### REFLEX CAMERAS,

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1909 will be

modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1909 will appeal to photographers the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and, wherever practicable, new features of an informative nature will be added.

**\*\* NOTICE—IMPORTANT.**—Our publishers ask us to notify intending advertisers that in order to complete the half-yearly edition of the ALMANAC (25,000 copies) for simultaneous publication on December 1, it will be necessary to close the pages in a fortnight's time; therefore, the latest date for receiving orders and copy will be Friday, October 16.

by 8 ground of this material cannot show if machine-cut. A single width of the fabric makes a good ground or full length children or for three-quarter heads of any other. The perfect method of making a black ground is to cover the frame as above and then hinge to it, one on each side and one on the top, supplementary frames covered with black serge, which will, when opened, form a sort of dark box. If the sitter is posed on a line with the front of the wings a dead black background will be secured, whilst the photograph should be full of atmosphere, not giving the sitter a cut-out appearance. Another very necessary piece of advice for securing good effects is to use backed plates for these subjects, there being a danger not only of clothes but the face being halated.

### COMBINATION GROUP-NEGATIVES.

In an article by Mr. H. V. Todd on the replacing of a moved figure in a group ("B.J.," July 3, p. 511), it was explained how to introduce a figure by a very simple method of double printing. The system is very convenient, and cannot be well improved upon when only a few prints have to be made. But when the order amounts to dozens, it is a saving in time in the long run to introduce the figure into the negative. When that is done the prints are, of course, obtained at a single printing, and the trouble of double printing is saved.

We will here explain how one, or more, figures may easily be introduced into a group negative. In the first place, the single-figure negative must have its film stripped off the plate. That is best done by the hydrofluoric method; but in the first instance it is well to harden the film by immersion, for ten minutes or so, in ten per cent. formaline, which treatment will prevent any expansion of the film when it is off the plate. After this hardening process, the edges of the plate are cut round about an eighth of an inch from the margins, and the negative is put into a bonite or xylonite dish containing water to which a few drops per ounce of hydrofluoric acid have been added. In a few minutes it will be seen that the gelatine film is coming loosened round the edges, after which, by gently rocking the dish, it can be floated free from the glass. The water is then poured off and replaced by fresh, two or three times, to get rid of the acid. The film is then removed and dried between fluffless blotting-paper, which will keep it flat and in a state convenient for after-handling. Should the negative be a small one, the gelatine film may be used as it is with careful handling. But if it be large, it will be best, prior to stripping, to strengthen it in the way directed in the article on the repairing of broken negatives ("B.J.," May 22, 1908, p. 391)—that is to say, it is given a thick coating of enamel collodion, placed level to set and allowed to dry.

When the stripped film is dry it is placed in the position it is to occupy in the group, and there secured with a few touches of indiarubber solution round the edges. The negative is then put upon the retouching desk, and the other films—the stripped one and that on the glass—are exactly cut round the outline with a keen-edged penknife, cutting cleanly through both down to the glass. The film negative is then removed, which the indiarubber permits being readily done. All that now remains is to scrape away the film on the glass, where the figure is to be, with a penknife, or, better still, with a retoucher's knife, the cut made in cutting through the two films serving as a guide. The cut-out figure is then put into its place, which will accurately fill, and secured with a few touches of ear white gum solution, applied to the figure portion only. We now have our combined negative complete, and the work has been neatly done, the juncture will not be perceptible. By this method of making the combined

negative the two negatives cannot afterwards, of course, be used as they were originally. This is a drawback to the method of procedure. This may, however, be met by adopting a different system. It is true that this latter involves a little more trouble, but it is often desirable to keep the two, or more, negatives intact for future use. In this case it is necessary to make a fresh negative by means of transparencies and to make the combination with them.

The transparencies may be made by contact printing on dry plates, and the films afterwards stripped by the method just described. Care, however, must be taken that they are all of the same printing value, otherwise a successful result must not be expected. The really best way of making the transparencies is, undoubtedly, by the carbon process, as in that way they will be quite of the same colour, and may easily be made of the same density. The glass upon which the transparencies are made should be thoroughly cleaned and then well rubbed over with French chalk, to facilitate the stripping. It is then coated with enamel collodion and, after that has well set, is put into cold water and the ether and alcohol washed away. The exposed tissue—which had best be that specially made for transparencies—is squeezed upon it and developed in the ordinary way. We may here add that the tissue must be deeply printed, quite as deeply as when the transparencies are required for enlarging from, otherwise it will be impossible to get good and vigorous negatives from them; in fact, there should be no really clear glass anywhere, except perhaps in the extreme high-lights, and even they may be slightly veiled with advantage. At this stage the transparencies should be compared to see that they are all of equal density. Should one be denser than the others, the development of that one must be continued until it becomes equal to the rest. Should one, however, prove to be thinner than the others, it is better to make afresh rather than to attempt to reduce the others to its level. The transparencies, while they are still wet, are next flowed over with a warm solution of gelatine—say one ounce of Nelson's No. 1 to a pint of water. The plates are then allowed to dry. When dry, they are again coated with the enamel collodion, and when this is dry the films are ready for stripping. They are cut round the edges and stripped off. The object of the second coating of collodion is to give strength to the films, that of the gelatine to prevent the second application of the collodion from interfering with the first, which it might do in the extreme high-lights if they were not thus protected.

The combination is made as follows:—A glass plate, an inch or so each way larger than the largest picture, is taken, and on that the largest transparency is firmly secured to the plate by strips of gum paper round the edges. The plate is then placed on the retouching desk, and the film with the first figure to be introduced is put into position and secured with touches of indiarubber solution round the edges. The two films are then cut through, as before described, the upper one removed, that underneath (and free) taken away, and the other adjusted in its place. It is then secured, as in the previous case, with a touch or two of gum, applied to the figure portion only; adhesive is not desirable, or necessary elsewhere. Other figures, if there are more than one, are dealt with in a similar way. If when the combination transparency is complete it is found that, through imperfect manipulation, there are any tiny bare spaces they must be filled in with colour.

Having our combined transparency complete, it only remains to make a negative from it, or several, if the order is a large one. This may, of course, be done in different ways, either by contact printing on a slow dry plate, or in the camera if different sizes are required, or by the carbon process, so that there is a choice of ways, all good, of getting the final negative.

## EXHIBITION OF PHOTOGRAPHIC PICTURES IN COLOURS BY T. AND O. HOFMEISTER AND H. W. MÜLLER.

GUM-BICHROMATE printing is running neck-and-neck with oil printing in the matter of colour, and whilst the latest attempts in the latter method are bidding for fame at the New Gallery, the Little Gallery at 24, Wellington Street, is offering a much more ambitious display in the gum process. Messrs. Hofmeister and Müller have been working for years towards artistic ends in multiple printings with various coloured pigments, and this fact may perhaps account for the great superiority in the gum work as now exhibited for the first time in this country over the more tentative experiments in oil which hang in Regent Street.

It should be explained at the outset that the peculiar varnished surface of the gum print, together with the magnificent proportions of the Hamburg pictures, demand more space and better conditions of lighting than the house in Wellington Street can offer, and this fact should be borne in mind by the visitor who sees them for the first time. But even under these somewhat detractive conditions the nobility of the works asserts itself, and one cannot help being struck by the look of importance which even the smallest and least successful of these works possess.

As practised by the brothers Hofmeister and their companion Müller, the multiple gum colouring has the decorative flatness and intensity which characterise most German work. Indeed, these pictures must be considered first and foremost as decorative schemes: they are naturalistic only to a slight degree, and that is their saving grace. The nature of their subjects demands such treatment rather than the melting tints of opalescent subtleties better suited to the sweet and airy pastorals of English schools of landscape art. These have as themes, the hoary castles, the massively disposed woods and plains, and the vapourless mountains of Germany. There is an uncompromising, full-bodied, clean-cut insistence in the subjects that induces the simple, almost diagrammatic colour that has been given them, and is germane to the country and nationality which produced them.

To any unacquainted with these phases of art, the pictures may prove at the first glance a slight disappointment; but when their mood is accepted, when they have been allowed to "grow upon" the spectator, he will find them fuller of charm and mastery than he thought they were. One soon gets used to their low tone, their restrained and dry colour, and before such an impressive view as "A Summer Afternoon," No. 2, one becomes convinced of the artistic truth of the impression. The shady avenue of trees, the stems of which are all but black, retires towards the distance where a town, bright in the low sun, gleams through the spaces between trunks. Above, the dense foliage fills all the picture, thus causing a concentration of interest upon the church-tower, which is the central spot. Viewed at a fair distance, all these items are in perfect harmony and true relation. Another view which is similarly naturalistic,

but less decorative in design, is "The Return Home," No. 5. Here we have a sky and distance that is as airy and true as a painting need be. It is the best of all in this respect, and almost the only one that, by its warmth and fine gradation, achieves anything considerable in aerial perspective. Most of the colour, and particularly the blue skies and green meadows, are too cold in colour. They appear to have been treated with flat unbroken blues and greens. This, of course, is fatal to fine effect, for a sky is never cold in colour. Indeed, it may be said that where these pictures fail is in their skies, generally speaking. Occasionally clouds are introduced—at least, they were, no doubt, in the original negative—but they have very obviously been picked out with the bright woolly edges dear to the photographer all the world over. They are in most cases only in lighter shades, culminating in white, of the heavy opaque "cerulean" variety of blue.

One or two of the works are practically in monochrome, and these are not the least satisfactory by any means. The first, "Bavarian Landscape," No. 12, which shows with splendid breadth a shepherd and his flock under pine trees, appears as though it were painted in black upon an orange-tinted paper. Another, which is a highly romantic view of the bridge and castle of Harburg (and is not in the catalogue), is printed in rich, warm dark green, with a touch of warmth in the sky at its lowest point and in a window. There are a few anomalies here, which, however, do not worry one who is not disposed to stick at trifles; but the castle is much too brightly lit for a moon so low as to be hidden behind the gable; and if Herr Hofmeister aver that it is the sun and not the moon, they must explain it dark night sky. This would be a fine and solemn nocturne, only there were more mystery in the foreground, and if some assertive white patches on the buildings were lowered in tone. In some cases the titles do not minister to the effect of the print. No. 15, for example, is called "Summer Sunset." It has positively a sky as at dead of night, and buildings and foreground practically in black silhouette; yet above the middle distance is a celestial orb of an orange colour. Now, let the least observant young and commonplace cyclist think what light there is in the sky at, say, an hour and a half before "lighting-up time," and he will agree that this black and deep blue picture, with a touch of orange, would have been more convincing if it bore the title "Moonrise." Similarly in "Summer Evening," No. 2, which is full of solemnity and breadth, the sky is at the same time so dark that it can only rightly be called "Summer Night." The brightest, and in many ways the best, is "Mill in the Taubergrund." It has no sky, but a background of wooded hills and a subject of near houses and a shaded pond.

There are twenty-eight pictures in all, and if the visitor will accept their decorative breadth and the conventionality of treatment, he will find them full of fine suggestion and romance.

F. C. TILNEY.

### A HAMBURG VIEW OF THE WORK OF MÜLLER AND THE HOFMEISTERS.

[The following notes are written by the friend and adviser of the Hofmeister Brothers and their colleague, Herr Ernst Juhl of Hamburg, who for years past has followed the steps which the present exhibitors have taken since the commencement of their work.]

The Hofmeister Brothers discovered their photographic métier, through the exhibitions held at Hamburg, in the year 1896, at which time they produced their first figure studies. From this class of subject they turned to landscape and to portraiture, and in all three fields proved themselves complete masters of their

art. They are, without exception, the most notable "pictorial" photographers which Germany has known since 1896, and even at the present time are surpassed by none.

From the beginning their work has been done in the gum-bichromate process, at first by one printing from the negative

since 1897 by the multiple-gum method. In the year 1898 first two-colour gum-bichromate prints were produced, and this time each year has been marked by their production of two-colour and multi-colour gum-bichromate subjects.

Throughout the period of their work the Hofmeisters have teachers of others, their most notable students being Mr. F. Müller and Dr. Kirstein. The former has been closely associated since 1893 with the two brothers, and many of the prints which have afterwards been produced as multi-colour have been photographed on holidays which all three have together. Not only that, but much of the subsequent work has been done together in the well-appointed photographic rooms of Herr Müller's villa. It is not surprising, therefore, that the prints are so discernible in both the subjects and the method of treatment are discernible in the respective pictures.

The prints now being exhibited in London are all multi-colour prints by the gum-bichromate process, made by Theodore and Hermann Hofmeister and H. W. Müller more or less in collaboration. They are, therefore, appropriately exhibited together. The pictures represent a period of work extending from 1903 to 1908. The oldest are "Hour of Sunset, Rothenburg," by Hofmeisters, and "The Path to the Village," the "Mecklenburg Landscape," and "Summer Evening," by Müller. From this limited selection of many pictures produced by the Hofmeisters and Müller since 1897 it is easy to appreciate the great progress which they have made in the mastery of colour harmony. As colour-records of nature are, of course, the outcome of general observation, not a re-statement of colour-notes made from Nature. One thing in a given colour is greatly modified by the after-print, and it is not possible to remedy completely an error made in the initial stages of the print.

The Hofmeisters' "Hour of Sunset, Rothenburg," is a striking example of the authors' talent for conveying their own interpretation of the "feeling" or "stimmung" of the scene to the viewer. The monastery perched on the height and lit by the setting sun contrasted with the twilight in the valley below, hardly have been rendered with such effect in monochrome, and the separation of the details in the dark foreground would have been impossible. The picture takes one back, as in a dream, to bygone times.

The pictures "The Load of Grass" and "Summer Afternoon" (1908) are conceived in quite an opposite spirit. In the first all the colours are soft and light, and in the second is an excellent rendering of plenteous sunshine. In neither case would a black and white version of the photographic negative have availed much.

Of Herr Müller's pictures, perhaps the "Village in the Harz Mountains" is the most original and the best in colouring. Two versions of it have been made, namely, the one exhibited showing the scene in bright daylight, and a second, from the same negative, depicting the aspect of the village by moonlight.

"A Relic of Olden Days" is specially noteworthy as an essay in colours, the coloured shadows on the wall being very successfully rendered. Another notable experiment is the picture "In the Harz Mountains," the effect of which, with its wealth of colour and soft tones, is very harmonious when seen in ordinary indoor lighting. The bright sunshine is excellently rendered—it is but seldom that a photograph conveys sunshine with so complete an effect—and the foreground of white window flowers harmonises with the bright tone of the whole picture. In the "Mecklenburg Landscape" the aerial perspective of the background, suggesting the effect of distance, is particularly worthy of notice. The picture, which dates from 1903, is recognisable as belonging to the Müller-Hofmeister technique by the clouds: in the later pictures, e.g., "In the Harz Mountains," it can be seen how the authors' progress in taste and handicraft has led to a more perfect representation. In "The Path to the Village" (1903) the sky is of clear blue colour, which, at any rate, is an improvement on the white sky of monochrome photographs of a few years back. There is perhaps less originality here than in other examples. The great expanse of foreground follows a fashion at one time prevalent both in England and Germany.

A particularly good example of selection is the "Water Mills in the Tauber Valley" (1906), which also is excellent in its colour rendering. The brownish roofs, the gable of pale rose colour, and the note of contrast between the green and the light bluish background make up, with the clouds, a harmonious whole.

Unfortunately, I cannot deal with the Hofmeisters' work at the same length, since the pictures at the time of writing are away from Hamburg, but in point of technique their gum-bichromate prints have much in common with those of Herr Müller.

When the Hofmeisters and Müller, in 1897, first exhibited their multi-colour pictures, it was not unusual to find the critics rushing in with hasty condemnations to discourage methods involving such labour and application. The critics easily forget that in new branches of work everything is a matter of development, and that to obtain the highest capacity a certain time must elapse, which in photography as an art is none too long. We may hope that our Hamburg friends will still persist in their progressive studies, and that they may provide further masterly work for our enjoyment.

ERNST JUHL.

## THE PHOTOGRAPHIC SALON DES REFUSÉS.

At the point of view of the English Links we must admit that no doubts as to the wisdom of holding an exhibition of pictures rejected by the American Committee of the Salon. It was, in fact, Providence, inasmuch as the risk involved might or might not resolve in favour of the rejected ones. Their last would have been worse than their first if it happened that, in the eyes of the world, the decision of the American few had been justified. But, to our minds at any rate, the protestors would gain more than they may lose by the exhibition. For, in connection with them also in the matter of the gallery, which, being a room in a business house, is incapable of holding all the able works, and therefore hangs a picking of them, and, to trust and believe, the best of them. The advantage of a good and good show over a large and mediocre one is in this

case on the side of the outraged Links also. There are 84 pictures in the room and a score or so upon the staircase.

No one will expect to find the American style rampant here, with its calculated avoidance of the ordinary in pictorial matters; but it may be expected that in some other way the visitor should feel the indispensable sensation of arrested attention, otherwise the affair would fall absolutely flat. Exhibition hanging is, after all, only window-dressing on a grander scale. We should think the visitor would feel sufficiently aroused by Mr. John H. Anderson's fine old print called "A Windmill." It is, without question, one of the very best oil prints we have ever seen, and has an unusually fine quality due to its being printed on thin Japanese India paper. It has every pictorial quality to recommend it, and of itself is sufficient to

demonstrate the fact that merit counted for nothing in the Salon selection. Another excellent work is Wm. A. Stewart's "Victory of Samothrace," a rather pedantic title for a lady seated near a small cast of the famous "Winged Victory." It is a beautiful print in every way. R. Dührkoop's "Portrait"—a charming head only, at full face—stands out, too, in its strong and quiet beauty. Alex. Keighley shows a large picture of a house in a village street, full of light and atmosphere, which he calls "A Word in Passing." Then there is a new name, Otto Ehrhardt, which promises fine things, and shows three portraits, fresh in idea, the strongest being an "Open-air Portrait" of an interesting boy at half-length. This is of what framers call a horizontal shape, and includes a simple piece of landscape; the open air is convincingly rendered, and the newness of the design is plucky. F. J. Mortimer's highly effective "L. and S.W.R." is here—the engine-driver subject—and if he sent it to the Salon he had no right to adopt such De Meyer methods, as it was exhibited here previously. His "Lion's Whelps" shows effectively an ironclad and its boats afloat. Charles Job and E. T. Holding both appear to great advantage, the former's "Sussex Lane" and "Gleam of Sunshine" being equal to anything he has yet done, which is say-

ing much. We must mention also S. G. Kimber's "A C. Portal," a highly effective light and shade subject; A. H. Blal "St. Mary-le-Strand" and "The King's Gate," both of wh have fine quality; E. O. Hoppe's large portrait of "W. Stead," which is broad and fine, but a little sad in its tone, and F. H. Evans's vigorous and highly pictorial "Maison Jean d'Arc." The same worker's "Sculptured Aisle of Chartres" that perfect technique that he always displays, and in this e the subject was one of almost insuperable difficulty, but he mastered it with his usual ease. We mention last a strike portrait by G. E. H. Rawlins of "Monsieur Demachy—Portra Essay in a New Limited-tone Process." It is difficult to exactly why the tone *should* be limited, but we suppose it n suit certain purposes. This portrait is admittedly high effective in its poster-like simplicity, which reduces the wh thing to little more than a solid black and white arrangem resembling that obtained by the stencil.

Altogether we must regard the little exhibition as havi fulfilled the purpose for which it was formed—that is to say, protesting against the selection of the Salon, and of taking t ultimate course known to parliamentarians as "going to t country."

## THE PHOTOGRAPHY OF COLOURED OBJECTS IN PRINCIPLE AND PRACTICE.

[The following article, which will be completed in a succeeding issue, is composed of several chapters from a book by Dr. C. E. K. Mees, to be issued under the title of "The Photography of Colour." Dr. Mees' treatise so well explains matters in the practice of orthochromatic photography that frequently present difficulties, that by permission of his firm we quote from advance sheets of the book. The full text of the latter we would recommend to the perusal of our readers, for the sake of the chapters on portraiture, landscape, reproduction work, and the tri-colour process, all in relation to the photography of coloured objects. Messrs. Wratten and Wainwright will shortly publish the volume at a nominal figure.—Eds. "B.J."]

### The Sensitiveness to Colour of the Eye and of Photographic Plates.

We have seen that the eye distinguishes light of different wave lengths by the production of an appearance of colour; that is to say, a ray of light containing waves of a length of 4,600 of our units would be called violet, and would be said to be of a violet colour, while if the waves were of the length of 6,500 they would be said to be deep red in colour. But the sensitiveness of the eye is not the same for waves of different lengths. The eye cannot perceive at all waves below 4,000 units, *i.e.*, what is

Fig. 6.

known as ultra-violet light; neither can it perceive rays which are above 7,000 units, so that to these we must regard the eye as insensitive. The eye is very little sensitive to the extreme violet rays between 4,000 and 4,500. The blue affects it more, and appears, as we say, bright. Between 5,000 and 6,000 the green appears as the brightest part of the spectrum; above 6,000 we have the bright reds, but the intensity rapidly falls off as the waves get longer, until beyond 7,000 we see practically nothing. We may then draw a curve showing the sensitiveness

of the eye to the spectrum (Fig. 6). It will be noted that the curve has a maximum at about wave length 5,800, but this only holds for intense light. As the intensity of the light diminishes, not merely does the eye see less, but the relative sensitiveness of the colours changes somewhat, shifting towards the blue. This is what is known as "Purkinje's Phenomenon." The explanation offered for it by Professor Schaum is sufficiently interesting and little-known to be worth repetition. It is known that the retina consists of rods and cones, of which the cones are considered to be colour-sensitive, and the rods colour-blind. In that part of the retina exactly opposite the centre of the pupil there is a small depression which contains no rods, but only cones, and here it is found that the Purkinje phenomenon is not existent, that the intensity maximum remains constant. From that we may conclude that the colour-sensitive cones alone display no Purkinje phenomenon, and that the phenomenon is due to the association of these cones with the colour-blind rods. It is found that the sensitiveness curve for this region containing only cones is identical with the curve of sensitiveness for great intensities of light, so that this is the curve of the cones. On the other hand, since the rods are much more sensitive to feeble intensities of light than the cones, as is shown by the fact that the sense of light remains after the colour can no longer be distinguished, the sensitiveness curve of the rods will correspond to the curve for minimum intensity; so that for minimum intensity the sensitiveness curve is due to the rods alone, and as the intensity grows the curve is more and more influenced by the cones, until with maximum intensity the curve of sensitiveness is almost entirely determined by the cones.

Just as the eye is unequally sensitive to light of different colours, so a photographic plate is unequally sensitive to light

erent colours. (Fig. 7.) But if we take an ordinary photographic plate and measure its sensitiveness, we shall find that it differs very markedly from the eye. The eye can see waves of shorter length than 4,000 units; a photographic plate can

Fig. 7.—Ordinary Plate.

ry much shorter waves, and can detect light which is quite invisible to the eye, this light being usually termed ultra-violet because it is beyond the violet. Also, the maximum of sensitiveness of a plate is in the violet, and all the red-orange and nearly all the green light is invisible to it. The eye may be said to perceive objects mainly by the green and orange light which they reflect. The ordinary plate perceives objects by the blue and violet light which they reflect, and this is a great weakness in the photographic plate when regarded as an instrument for perceiving and recording coloured objects, because the plate which a photographic plate makes of coloured objects is entirely from that which the eye makes.

It was found by Vogel that by treating plates with dyes they can be given, besides their usual sensitiveness, a secondary sensitiveness in approximately the region of the light which the dyes absorb. Thus, if a plate is soaked in a solution of erythrosine, which absorbs the yellowish-green, it will be sensitive to the yellow-green, besides being sensitive to the blue and violet. Plates which have been treated in this way are those which are known as "orthochromatic," the word implying that they can render objects in their true colour values. The ordinary orthochromatic plate, which is made by putting some erythrosine into the emulsion, has a sensitiveness curve of the following type (Fig. 8), and it will be seen at once on

Fig. 8.—Erythrosine (Allochrome) Plate.

comparing this with the sensitiveness curve of the eye (Fig. 9) the plate is certainly somewhat better in consequence of its treatment with erythrosine, it cannot be described as at all comparable in sensitiveness with the eye. It has an enormous sensitiveness in the blue and violet, it has the sensitiveness to the ultra-violet, which the eye has not at all, it has very little sensitiveness indeed to the blue-green, a maximum of sensitiveness in the yellow-green, and an enormous sensitiveness to the red. It may be taken that if we take the blue to include the whole spectrum up to 5,000, the red to be the spectrum from 5,000 to 6,000, and the green from 5,000 upwards, that the sensitiveness of the ordinary orthochromatic plate is distributed in the ratio of 40 parts in the blue, 1 part in the green, and none in the red. If we consider that the eye sees the three parts of the spectrum as of equal intensity, the orthochromatic plate, beside the fact that it is not sensitive to the red, has only one-fortieth of the sensitiveness in the blue that it would require to be equal in sensitiveness to the

eye, however, instead of sensitising a plate in the way we have described we bathe the finished plate in a solution of certain new dyes called isocyanines, we can prepare a plate which

is very much more sensitive both to the red and to the green. Two years ago Messrs. Wratten and Wainwright, Ltd. succeeded in preparing a plate in this manner, the plate being sensitive to both red and green, and this plate they called the "Wratten Panchromatic plate." The plate is sensitive to the whole visible spectrum, although it has a considerable excess of sensitiveness in the blue; this excess is very much less than in the case of the ordinary orthochromatic plates, and there are no absences of sensitiveness throughout the whole spectrum. The distribution of sensitiveness in this plate is shown by the following curve (Fig. 9), and it may be said that  $\frac{2}{3}$  of its sensitiveness is in

Fig. 9.—Panchromatic Plate.

the blue, 1-16th in the green, and 1-16th in the red; so that the sensitiveness to blue is seven times too great compared with the rest of the spectrum, while the sensitiveness to green and red together is  $\frac{1}{8}$  of that required to have the same sensitiveness as the eye.

In order to attain the same relative sensitiveness as the eye, it is necessary with an ordinary orthochromatic plate, or with the Panchromatic plate, to use absorbing colour filters which shall diminish the excess of blue light, and it is the consideration of these colour filters and of the effect which they will have on the total sensitiveness of the plate, that is, on the exposure required, which we must now consider.

### The Multiplying Factor of any Sharp-cut Filter.

Suppose that we imagine that we have a filter which has perfectly sharp absorption—that is to say, which cuts a clean section out of the spectrum, passing only light between two definite wave lengths and without any absorption of that light; then, if we wish to find the multiplying factor of this filter, we must consider it in relation to the sensitiveness curve of the plate.

It will be convenient, first, to consider a filter which does not transmit light below 5,000 A.U. (Fig. 10), i.e., which absorbs the whole of the blue-violet and ultra-violet, but does not absorb any green or any red. This filter will be a bright yellow in colour, yellow being, as we have seen, made up of green light and red light—that is to say, yellow being simply an absorption of blue. Consider the effect of this on an orthochromatic plate which has 39-40ths of its sensitiveness in the blue, and 1-40th in the green. The yellow screen will remove all the blue light, i.e., 39-40ths of the active light, and it will increase the required exposure 40 times, so that it is what we term a 40-times screen.

Now consider the same screen to be used with the Wratten Panchromatic plate. With this plate  $\frac{2}{3}$  of the whole sensitiveness is in the blue,  $\frac{1}{3}$  in the red and green. The screen will then remove  $\frac{2}{3}$  of the active light, leaving only  $\frac{1}{3}$  to act; it will increase the exposure 3 times. This example shows at once the intimate relation between the plate and the multiplying factor of a screen.

Take now a screen cutting the spectrum sharply at 5,500 (Fig. 11). This screen will be bright orange in colour. It transmits all the red, orange, and yellow-green light. It absorbs the blue-violet and blue-green light, i.e., adopting our convention as to the division of the spectrum, it transmits the red and half the green, and absorbs the blue and half the green. The effect of this on the ordinary orthochromatic plate is to remove the blue sensitiveness, 39-40ths

of the whole sensitiveness of the plate, but inasmuch as this plate is not sensitive to the blue-green, and the yellow-green region of sensitiveness which represents the other 1-40th of the sensitiveness of the plate is transmitted by the screen undiminished, the screen will only increase the exposure 40 times, being the same increase as is shown by the former screen.

On the Panchromatic plate, however, the matter is different;  $\frac{7}{8}$  of the sensitiveness of the plate is in the blue and is removed by the screen, 1-16th is in the green and half of this is removed by the screen, so that the sensitiveness left is 1-16th due to the

sensitiveness of this plate in the green is 1-40th of its total sensitiveness, so that we must use a screen which will give us 1-2 of its total sensitiveness, 1-40th being in the green, and 1-40th the blue. That is, it must cut off 38 of the 39 parts of blue sensitiveness which the plate has, and the same will increase exposure 20 times.

With the Wratten Panchromatic plate we have 1-16th the sensitiveness in the red and 1-16th in the green, consequently we must have 1-16th in the blue; that is, the total sensitiveness will be 3-16ths, and the increase of exposure required by

Fig. 10.—Filter not transmitting light below 5,000.

Fig. 11.—Filter, not transmitting light below 5,500.

undiminished red-sensitiveness, and 1-32ndth being half of the green sensitiveness; the total residual sensitiveness, therefore, being 3-32ndths of the original sensitiveness, this screen will, on the "Wratten" Panchromatic plate, increase the necessary exposure 102-3rds times.

Again, consider a screen cutting the spectrum at 6,000, that is, transmitting all the red but absorbing all the blue and all the green. The ordinary orthochromatic plate has no appreciable sensitiveness in the red, and therefore could not be used in practice with such a screen. The "Wratten" Panchromatic has only 1-16th of its total sensitiveness in the red, and consequently this red screen will on that plate be a 16-times screen. Let us now examine into the multiplying factor of the screen (Fig. 12) which will give correct reproduction of red, green, and blue, as seen by the eye. We have assumed in all these figures that in order to get correct reproduction the sensitiveness for red, green, and blue should be equal; that is, we have chosen our units with that condition in mind. On the orthochromatic plate we have no red-sensitiveness, but the nearest approximation to correct rendering that we are able to obtain will be given if the green and blue are of equal intensities; i.e., we require a sensitiveness in the blue equal to the sensitiveness in the green. The

screen will be 5 1-3rd times. This screen will reduce the  $\frac{7}{8}$  sensitiveness of the blue to 1-16th, i.e., it will remove 13-14ths the blue sensitiveness. Two points must be noted here:—

First, that the Panchromatic plate will require very much

Fig. 12.

less absorption to fully correct it than will the orthochromatic plate, and consequently that not only is less exposure required but that a lighter screen is required; that is to say, in the case we had to remove all but 1-39th of the blue, but in the other 1-14th of the blue was left, and consequently a screen which would give correct reproduction on an ordinary orthochromatic plate will over-correct the Panchromatic plate.

C. E. KENNETH MEES, D.Sc., F.C.S.  
(To be continued.)

## RAYONS CONTINUEURS AND NEGATIVE RAYS.

### II.

In November, 1899, in the course of his excellent Trail Taylor Memorial Lecture, Major-General J. Waterhouse gave a most interesting account of the then almost forgotten subject of *rayons continueurs*, including particulars of experiments of his own, all strongly confirming the observations of Becquerel.

More recently, the subject has been taken in hand by M. P. Villard, whose researches (extended also to modern photographic processes) have fully confirmed the results of the older investigators, and also established some new facts of much significance. The con-

tinuing action of the less refrangible rays is, he finds, entirely dependent upon the presence of a soluble silver salt in the film, and appears to be quite of a similar nature to physical development by means, say, of gallic acid, etc., except that no action can be produced by means of *rayons continueurs* after fixation, as can be done by physical development. An image which has been strengthened by the application of *rayons continueurs* may be further developed by a physical developer, and such an image will gain a considerable advance upon a non-continued image, but finally

the latter will overtake it and the two will be equal in the end if development be prolonged. On the other hand, developers not containing free silver develop the non-continued image at least as quickly as the continued one, and may finish by producing a stronger image in the former case on account of the negative action which the rays may have had on the image exposed to them. These observations resulted from experiments made with modern chloride and bromide papers and plates; they do not seem entirely in agreement, in one respect, with the phenomena observed in the case of Daguerreotype plates, but it appears from some remarks of Waterhouse, in the nature previously referred to, that metallic silver in intimate contact with its haloid salts, as occurs in the case of Daguerreotype plates, has an effect very similar to an excess of silver nitrate in a solution, and that may perhaps account for the action of the *rayons continuels* on Daguerreotype plates.

Ordinary gelatino-bromide and gelatino-chloride plates, then, as they contain no soluble silver salt, are consequently not susceptible to continuing action, but the author adds in a footnote<sup>4</sup> that, when the grain is very fine, continuing action may be produced by treating them with nitrate of silver or even by simply plunging them in water containing a trace of ammonia. I presume that a printed result is referred to here, but, not having had the opportunity of doing the original articles, I am not clear on the point.

Willard's results in regard to the negative action of red rays are very striking. It affects all plates and papers whose sensitiveness depends upon silver salts, whether a soluble salt be present or not, and destroys the images upon them, whether visible or invisible. In the case of silver chloride, all rays from the D line into the extreme red have this destructive action, but in regard to silver bromide, only the extreme red rays beyond the A line have such effect. The action is so strong that by exposure to negative rays a developable image may be entirely removed from a gelatino-bromide or gelatino-chloride plate (alkaline development being in question) and the film restored almost entirely to its original state of sensitiveness; it is noted: "the sensitiveness is so exactly restored that a very precise comparison is necessary in order to find a difference." To gain this result, when a bromide plate is in question, the extreme red rays of a spectroscope must be employed; but the image may be completely removed from a chloride plate by exposure under ordinary yellow glass. This is because such glass passes very largely the infra-red rays which have the negative action and, in the absence of soluble silver salt, there is no continuing influence, while other rays passing the yellow glass are not among those to which silver chloride is sensitive. It may be noted that the work of all investigators contradicts the opinion of Draper that green and blue rays have negative action.

Waterhouse mentioned that some of the phenomena he described had very easily been observed with the ordinary P.O.P., using coloured glasses. This led me to undertake some experiments two years ago, and certainly I found the work very interesting. The method usually employed was to form graduated scales, by imprinting bands of various degrees of intensity on white P.O.P. and to the effects of exposing pieces of such scales to light under various coloured glasses of the ordinary commercial kinds, which I have done not very much in quality. The very first experiment ended conclusively the reality of the continuing action; three tints, produced by exposures near an incandescent gaslight of 8, 3, and 1 minutes respectively, showed a faint tint in the first case and a just perceptible coloration in the second, while the effect of the smallest exposure was practically invisible against the unexposed ground. On exposing a piece of this imprinted paper to daylight under yellow glass, all the tints steadily darkened, and I noted at the conclusion of the action: "the three steps have quite considerable density, in increasing contrast to the reserved piece, and would represent strong blue after toning and fixing" (i.e., if forming part of a picture). Exposure under green glass had a similar result, but not quite so marked as the other. Altogether, a considerable number of experiments were carried out, and the following are some of the conclusions reached at:—

1. Stable green and yellow glasses give strong continuing action. This is not equivalent to the effect of proportionately longer exposures. On a print from a negative, for instance, the continuing action will greatly increase the contrast among the

weaker half-tones, while having comparatively much less effect on the dark parts of the print.

Ruby glass has a similar continuing effect, but it is extremely slow, and the results finally arrived at seem in no way superior to those given by the green and yellow glasses.

The continuing action is a special property of the less refrangible rays. Auxiliary exposure to white light certainly gives a small amount of increased contrast to the weak parts of an image, but such as is quite insignificant in amount as compared with that given by *rayons continuels*.

It has been stated that white light of very low intensity would have the same action as the *rayons continuels*. Auxiliary exposures were compared which were made with intensities which gave an equal faint discoloration to white P.O.P. after ten hours' and one minute's exposures respectively, and the small increases in density found in photographic images subjected to these exposures were practically identical.

Pre-exposure to yellow or green rays appeared to have no greater sensitising effect than when made to white light. There was, however, a little uncertainty as to this in the case of green glass.

The ruby and the yellow glasses both have strong negative action under some circumstances. In regard to P.O.P. simply darkened by light, without any further treatment, it appears to be only ruby glass which has such action, and that only upon very darkly printed tints. This action is very slow, and my experiments were not very satisfactory. After prolonged exposures under ruby, however, distinct falling off in density was evident, although not very great in degree. But on further prolonging the exposures, density again increased and appeared finally to regain its original depth. It must be remembered that ruby glass passes a certain amount of blue light, so that we have opposing influences in action. While this negative action was in progress in the darker parts of the print, the ruby glass was effecting continuing action on the paler shades.

The presence of soluble silver salts appears to be antagonistic to negative action (probably because favourable to continuing action). When, after imprinting the image, the print was well soaked to remove the soluble salts, and in other cases also treated with sodium chloride, the negative action on subsequent exposure under ruby or yellow glass was far more distinctly evident. Those prints treated with sodium chloride were not very differently affected from the simply washed ones. As an example, showing the action of negative rays on prints after removal of soluble silver salts, I will give the details of one experiment. Of two strips, having a scale imprinted upon them containing a variety of gradations, one was simply washed and the other was treated with sodium chloride, and when dry they were exposed together under ruby glass. After two hours a great change had occurred, but a very prolonged continuation of the exposure produced no further alteration. The results obtained were a very conspicuous weakening in the shades of large and medium density; in a band of small density, the effect was obscure and, in a very faint band, there was evidence of slight continuing action. The effects on both strips had been very similar.

My experiments in this direction were not very exhaustive. I found, however, that exposure under yellow glass, after washing, also had a strong reducing effect on the darker portions of images, but when a piece of green glass was superposed on the yellow, no action at all occurred. No doubt that was because it is the red rays which are passed by the yellow glass which have negative action, and these are cut off by the green glass.

There seemed, in many of the tints which had undergone reduction through negative action, a tendency to darken again to some extent under continued exposure to the same rays, thus showing a similar effect to that described by Foucault and Fizeau in regard to Daguerreotype plates. No doubt the effect to be obtained depends to a great extent on an equilibrium being established between opposing influences, and mass action evidently has a large part in determining whether the change in density is to be positive or negative, but there also appears to be reason to suspect that possibly the products, resulting from the action of rays of different wave lengths on silver salts, are not identical in nature. This view gains much support from the fact observed by Mr. F. E. Ives and Dr. Vogel that, under some circumstances, the velocity of development is much smaller in respect to images formed by red or yellow rays than to those formed by blue ones. Messrs. Mees and Sheppard remark that such a difference in the nature of the products given

<sup>4</sup> "Journal de Physique," iv., 1905, p. 620.

by the various rays is almost inconceivable, but I do not quite understand why.

The whole subject of the photo-chemical action of the less refrangible rays appears to me to deserve far more attention than it has hitherto received. Its importance, no doubt, is mostly on the theoretical side, and our theories of photographic action will necessarily be faulty unless they take into account the mysterious phenomena connected with these rays.

On the practical side, too, their properties may perhaps have some useful applications, such, for example, as in modifying the character of prints where softer effects than can be obtained by direct printing are desirable. Prints on P.O.P. of any degree of softness can be made from a hard over-developed negative by printing under it till the shadows have a satisfactory depth and then completing the prints by developing with *rayons continuaturs*, that is to say, exposing them to daylight behind glass of a fairly deep yellow tint for a suitable time, when an amount of detail will be brought out in the less exposed parts which it is practically impossible to obtain by direct printing. Much the same effect can be so obtained as would have resulted had the negative been reduced with ammonium persulphate, but by the use of the yellow glass the qualities of the pictures may be modified at pleasure and most remarkable changes shown in their scales of gradations.

H. J. CHANNON.

### THE "GREAT CONGRESS" OF PHOTOGRAPHERS.

ONE of the most curious meetings which our connection with photography has ever led us to attend was held last Saturday evening in the hall at the head of the "Court of Honour" in the Franco-British Exhibition. It was the meeting of the "great congress of photographers," our information in regard to which had been derived from a prospectus to which a reference was made in the "Journal" for September 18. This prospectus is an extraordinary production. It refers to a "committee," the members of which are not named. It commences a hopeful paragraph with "The following trains will be run . . .," but names no trains. In one case it states that those attending the "great congress" will be enabled to use their cameras in the grounds free of charge, whilst in the next it shows that the privilege to photograph without charge has nothing whatever to do with attendance at the "congress," but is granted by a special permit. In short, the so-called "congress" is only the semblance of a congress, created to lend some colour to a wholesale concession by which photographers visiting the exhibition on a certain day save the customary fee of one shilling charged for a permit to photograph. A laudable object enough, this latter, and one which, we understand, has been appreciated, but scarcely a sufficient reason for calling together a meeting and talking of a "great congress." In short, we have the edifying spectacle of a "congress" summoned in order to get for nothing what anybody can buy for a shilling, a view of the "congress" which we are interested to find taken by a self-declared supporter of it, Mr. F. C. Lambert, M.A., F.R.P.S., who, writing in the "Daily Telegraph" of September 18, says:—

"The meeting is arranged to occupy not more than one hour, and be over in ample time for those attending to see the illuminations and fireworks, which are to be of a special character. But what will, perhaps, prove the chief attraction to the majority of photographers attending this big meeting is that a special permit to take photographs on this occasion may be had, free of charge, from the organising secretary, Mr. Human."

But of the "congress" itself. When at 7.15 Mr. T. E. Freshwater took the chair, he was supported on the platform by Sir John Cockburn, Mr. Chapman Jones, Mr. C. H. Oakden, Mr. A. Haddon, Mr. C. P. Butler, Mr. S. J. Beckett, Mr. W. R. Stretton, and the hon. sec. of the "congress," Mr. E. R. Human. We looked in vain for others who had been announced as speakers or supporters—viz., Sir Henry Trueman Wood, Sir Joseph Swan, Mr. Andrew Pringle, Mr. John Spiller, and Mr. Snowden Ward—but as the announcement of the presence, at any rate of one, of the above persons had been made in the prospectus without that person's sanction, and in opposition to his expressed wish, the absence of others was perhaps not surprising. Some letters of regret were read by the secretary, but we could catch the names only of Mr. Spiller, and of Sir Benjamin Stone who had been unable to send a promised paper. A series of short addresses was then delivered. Sir John Cockburn referred

to the new interest given to life by the practice of photography and the real knowledge as compared with book knowledge thus acquired of many subjects. In expressing his pleasure at being present he mentioned that he had passed his life in Australia, and that photographic circles in this country were quite strange to him.

Mr. Chapman Jones put forward a plea for the restoration of photography as a pictorial art to the position it occupied before the advent of "control" processes.

Mr. C. H. Oakden spoke on photographic societies.

Dr. Lindsay Johnson, who, it was understood, had travelled one thousand miles in order to attend the "great congress," plunged into a technical discourse on colour matters. He first outlined what we understood to be a system of colour-cinematography, the details of which did not reach the middle of the hall in such a form as to be reportable, although from the fact that Dr. Johnson spoke from what appeared to be a packet of MSS. or printers' proofs, there is reason to hope that his communication will not fail eventually to reach the public. He next explained that he had devised a novel system for the development, etc., of Autochromes, consisting, so far as could be gathered, in the omission of the intensification. He also announced still another discovery—viz., the re-use of spoilt Autochrome plates. For this purpose he removed the emulsion coating and placed the plate (bearing the starch grain filters), film to film, with a panchromatic plate, which he then exposed in the camera (through the starch grain plate), developed, reversed, and bound up with the starch-grain plate by means of register marks. The result of this series of difficult operations had, Dr. Johnson stated, been most encouraging, and he regretted that he had forgotten to bring with him the specimens he had prepared.

This concluded the proceedings of the "congress," and the attendants at the meeting, who, we are told, numbered over 300, were at liberty to visit the fireworks, which, the prospectus declared, were to be "of a special nature, photographically." We are also informed that 957 camera permits were issued, and that the day's proceedings passed off successfully.

It is hoped that on the next occasion when a co-operative outing is organised, its promoters will spare themselves the trouble of mixing a "congress" with it; a little reticence on the present occasion would have saved them from holding themselves and others up to ridicule.

AN ECHO OF THE CONGRESS.—The following extraordinary paragraph appeared in the "Morning Post" of Monday last:—

"More than a thousand members of the London and Provincial Photographic Association attended a congress at the Franco-British Exhibition on Saturday, when papers were read by Sir J. Cockburn, Sir H. Trueman Wood, and Mr. H. Snowden Ward."

The membership of the London and Provincial Photographic Association is—well, not a thousand, and the two last-named persons were not present, nor took part in the "great congress." Shade of Mr. Vincent Crummies, "How do these things get into the papers?"

ROYAL PHOTOGRAPHIC SOCIETY.—The following lectures will be delivered at the New Gallery, those illustrated with Autochromes at 7.30, the others at 8 p.m.:—

Friday, October 2.—Autochrome Lecture, "The Thames from Kew Gardens to the Sea." By J. McIntosh.

Saturday, October 3.—"Some Glimpses of the Green Isle and its People." By C. H. Oakden, F.R.P.S.

Monday, October 5.—Autochrome Lecture, "The Thames from Cirencester to Maidenhead." By J. McIntosh.

Tuesday, October 6.—"Wild Birds and their Ways." By W. Bickerton, F.Z.S.

Wednesday, October 7.—Autochrome Lecture, "The Thames from Windsor to Richmond." By J. McIntosh.

Thursday, October 8.—"The Gorges of the River Ardèche." By G. E. Thompson.

Friday, October 9.—Autochrome Lecture, "The Thames from Kew Gardens to the Sea." By J. McIntosh.

Saturday, October 10.—"Southwell Minster." By E. W. Harvey Piper, Hon. M.S.A.

THE LATE J. G. BREWERTON.—The death took place at Oxford last week of Mr. J. G. Brewerton, who till within a few months ago carried on business as a photographer in High Street. The deceased was 65 years of age at the time of his death.

## FORTHCOMING EXHIBITIONS.

tember 11 to October 24.—Photographic Salon. Sec., Reginald Craigie, 5a, Pall Mall East, London, S.W.  
 tember 17 to October 24.—Royal Photographic Society. Sec., J. McIntosh, 66, Russell Square, London, W.C.  
 iber 13 to 17.—Southampton Camera Club. Entries close October 6. Exhibits by October 8. Hon. Sec., S. G. Kimber, Oakdene, Highfield, Southampton.  
 iber 14 to 17.—Rotherham Photographic Society. Entries close October 5. Sec., H. C. Hemmingway, Tooker Road, Rotherham.  
 iber 22 to 26.—Hove Camera Club. Entries close October 15. Sec., W. Chater Lea, Cransley Lodge, Dyke Road Avenue, Brighton.  
 iber 27 to 31.—Heaton and District Camera Club. Entries close October 12. Secretary, George C. Urwin, 24, Tenth Avenue, Heaton, Newcastle-on-Tyne.  
 iber 28 to 29.—Watford Camera Club. Entries close October 22. Sec., W. Branch, 100, High Street, Watford.  
 iber 4 to 7.—Hackney Photographic Society. Entries close November 2. Secretary, Walter Seife, 70, Paragon Road, Hackney, N.E.  
 iber 20.—Redhill and District Camera Club. Entries close November 7. Sec., J. Paterson, Ness House, Redhill.  
 iber 23 to 26.—Lancaster Photographic Society. Sec., J. Holt, 11, Fern Bank, Lancaster.  
 iber, 1908, to January, 1909.—Kiew International Photographic. Sec., S. T. Horovitz, Technical Society, Kreshchatik, 10, Kiew, Russia.  
 1909.  
 ary 6 to 27.—Northern Photographic (Manchester). Entries close December 11, 1908. Sec., S. L. Coulthurst, Broad Oak Road, Worsley, Manchester.  
 uary 13 to March 13.—South London Photographic Society. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

## Patent News.

*process patents—applications and specifications—are treated in the Mechanical Notes.*

The following applications for patents were made between September 19:—

ENT PICTURES.—No. 19,297. Improved process for manufacturing pictures. Alfred Julius Boulton, 111, Hatton Garden, London.

ER.—No. 19,339. Portrait shutter. Frank Dean, 20, Nassau Street, Mortimer Street, London.

IGHT LOADING.—No. 19,367. Improvements in means for loading and unloading photographic sensitised plates in the daylight. Herbert Richard Allen, 18, Southampton Buildings, London.

ATOGRAPHS.—No. 19,742. Automatic fire-extinguishing apparatus for cinematographs. William Charles Cooke, 57, Chancery Lane, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

C-INK PROCESS OF COPYING PLANS.—No. 19,534, 1907. The invention is a method of producing by means of iron salts a lithographic or other printing surface from which copies can be taken in greasy ink. It is a development of the process described in Pat. No. 11,312, 1906 ("B.J.," July 12, 1907, p. 525, or "J." Almanac, 1908, p. 657).

In the previous processes the solving power of the ferrocyanide of potassium on a gum-ferric film was used for the purpose of producing a photo-impressed stencil film, and to produce positive copies of positive transparencies on the surface of the supporting material. Under the present invention the application of the perking effect of a water solution of ferrocyanide of potassium (or its equivalent) on a colloidal ferric film, or the absorbent power of

the film for the solution, under the controlling effect of the action of light and the consequent mechanically repellent action of the water-impregnated film for spirit or greasy or printers' inks, is utilised for producing, on the surface of the film itself, a negative copy from the transparency. The invention also includes the use of an improved support for gum-ferric film for use in both the surface and stencil processes.

Such a colloidal ferric film is used and applied as an effective substitute for the chrome films now in general use throughout the processes of photo-mechanical printing, wherever it is found to be applicable for the purpose of obtaining photographic impressions for the production of multiple copies by machine or mechanical printing, either from the surface of the photo-impressed film, or from the surface of stone or metal plates, or by means of etched or engraved relief or intaglio metal plates or blocks, a solution of ferrocyanide of potassium being substituted for the water solvent.

Before being acted upon by light, the colloid-ferric film will be quite permeable by a water solution of ferrocyanide of potassium, but after exposure it will become more or less impermeable, according as the light has affected it. Such a film is exposed to the action of light beneath a transparency in the usual way, for such a time as shall render the parts thereof, on which the light has acted, more or less impervious to a solution of ferrocyanide of potassium.

It may now be said to be photo-impressed, and is ready for application and use in the various branches of photography and of photo-mechanical process printing work, according as it is subsequently treated, as is indicated, and in some cases described as follows:—

Throughout this specification the terms "positive" and "negative" are used in relation only to the original transparency used.

According to one part of the invention the film in this light-affected condition, if on the surface of paper, glass, etc., will be treated with a water solution of ferrocyanide of potassium (or its equivalent) until the unexposed parts absorb same, in which condition the unexposed parts will (after the usual collotype etching treatment) repel printers' inks; and then the surface so prepared is inked up, the ink attaching itself to the exposed or non-absorbent parts, as in the collotype process with bichromated gelatine, and multiple copies may be produced therefrom by contact surface printing in a press in the usual way. These prints will be negative copies of the original transparency used.

If a single photo-copy only is wanted, either in pigment or in litho transfer or in printers' ink, the photo-impressed film is first inked up all over, then this inked copy is immersed in a bath of ferrocyanide of potassium, stopping the action when desirable by placing the copy in a water bath. Then the superfluous ink on the absorbent unexposed parts is removed by gently rubbing, when a negative copy on a blue ground of the transparency will result; these operations being all similar to those followed in preparing the bichromated gelatine film photo-litho transfers, as at present used in printing processes.

If a stippled, grained, lined, or hatched original has been used, and the copy obtained as last described is in litho transfer, or other suitable greasy ink, this copy will transfer to the surface of stone or metal, or the photographic impression may be produced directly on the surface of the stone or metal plate. And the metal surface may be printed from by contact surface printing; or it may be converted by acid etching into a relief or intaglio printing plate or block for use in typographic printing.

And if the film has been covered over its surface with ordinary pigmented ink, enamel, or varnish, and only a single photo-copy be required, the blue coloration induced upon the carrier or material coated with the film in the parts unexposed to light, in developing with the ferrocyanide of potassium, may be removed in a bath of common soda or of oxalate of potassium.

In the production of photographic copies of transparencies, and in their subsequent treatment, where liquid spirit inks or greasy or turpentine inks are used, and in which photo-sensitive gum or gelatine colloidal ferric films are employed, a penetration of the film, and spotting or speckling of the surface of the substratum after the film is removed, has been found to occur, constituting defects in the photo-copy produced; and one of the objects and effects of the invention has been to obviate these defects in such films so as to make them of practical utility in their application in

pigment photographs, and in litho or turpentine printers' ink photo-work, as applied to the photo-mechanical printing processes. And it is accomplished by the use in connection with the colloidal ferric film solution—which may be assumed to be of the kind now in general use for producing positive copies in Prussian blue stain—of such a substantial proportion of alcohol or other spirit as shall dissolve all foreign impurities in the thickening substance used to form the film, such as certain gums or resins and greases, which would remain insoluble in water, and which would be present in suspension in the water solution of the colloidal substance used to form the ferric film. The effect is that a homogeneous solution and a uniform and impervious film is formed capable of resisting the penetration of the spirit inks, pigments, or enamels, or the greasy litho-transfer inks, which may be superimposed upon it. The proportion of alcohol to be used will vary with the colloid used, but some 20 per cent. of the solution used will produce efficient results.

A more homogeneous film is thus produced forming a more perfect resist to the penetration of greasy litho-printers' inks, or to any other greasy, alcoholic, spirit or turpentine pigmented inks or the like which may be used in connection with the processes herein referred to.

In using the film on the surface of paper for photo-lithographic transfer purposes to stone or metal, difficulties are experienced in removing the inked film from the soft and absorbent felted surface of ordinary paper, without extra rubbing, in the processes of development, and so endangering the lines of the copy, and from the want of adhesion of the inks to the sized surface of ordinary soft paper, or from the soft paper parting with the ink irregularly to the stone or metal surface. These difficulties are overcome by using as a substratum to carry the film a paper which has already been coated with a hard surface, say of sulphate of barium ("baryta" papers).—Henry Lionel Shawcross, Water Engineer's Office, Dale Street, Liverpool.

The following complete specification, etc., is open to public inspection before acceptance under the Patents Act, 1901:—

CAMERAS.—No. 17,624. Photographic cameras. Optische Anstalt C. P. Goerz A. C.

### New Trade Names.

SWANS' NECKS (DEVICE).—No. 304,225. Chemical substances used in manufactures, photography or philosophical research and anti-corrosives. Chemische Fabrik Helfenberg, A. G. vorm. Eugen Dieterich, Helfenberg, bei Dresden, Germany, manufacturers. June 25, 1908.

### New Books.

ORTHOCHROMATIC PHOTOGRAPHY.—In "The Photo-Miniature" (No. 92) just issued, the theory and practice of ortho work is treated under the title of "Practical Orthochromatics." The matter is well adapted for a first and pleasant introduction to the subject. (Dawbarn and Ward, Ltd. 6d. net.)

"SOUVENIR ANNUAL" OF THE PHOTOGRAPHERS' ASSOCIATION OF AMERICA.—Here is tangible evidence of the real activity of the Convention of Professional Photographers held at Detroit for four days in July last. It is the custom of the Photographers' Association of America thus to produce a record of its doings, and the present volume, which owes its admirable form and arrangement to Mr. Frank V. Chambers, of the "Camera," contains much which renders it worthy of preservation even by those whose absence from the meetings deprives it of its virtue as a souvenir. The Annual is not in any sense a formal report of the Convention proceedings, but a collection of short articles and reproductions of portraiture by leading American photographers. The former relate to both the commercial and æsthetic sides of the photographer's occupation, and are by such men as B. J. Falk, Pirie Macdonald, Dudley Hoyt, and E. Goldensky. Herr R. Dührkoop contributes an article on "Camera Pictures and their Effect on Culture."

## New Apparatus, &c.

The "Tudor" Roller Squeegee. Sold by Houghtons Ltd., 88 and 89, High Holborn, London, W.C.

A pattern of roller squeegee made specially for hard regular trade work reaches us from Messrs. Houghtons, who have just marketed it under this title. The squeegee is mounted on a substan-

tial cast-iron frame, the spindle, which carries the roller, running in ball-bearings. The apparatus is of a kind which one purchases with the object of keeping it in use for a lifetime. Its price is 7s. 6d.

The "Jupiter No. 2" Electric Studio Lamp. Sold by John J. Griffin Ltd., Kingsway, London, W.C.

A remarkable lamp for studio portraiture by artificial light has just been placed on the market by Messrs. Griffin at the opportune moment when many photographers are contemplating the installation of some form of artificial illuminant in the studio. The "Jupiter No. 2," as it is called, owes its design and manufacture to the same

source which produced the "Jupiter" flash arc, but the present lamp is not in any way a further development of the flash system. On the other hand, the essential point in the lamp consists in the automatic adjustment of two open arcs arranged in series. This is done by a system of levers which hold the carbons constantly in the right position, and gives an even burning of the two arcs. The result is a light of remarkable intensity, sufficient to allow of ex-

of one-tenth of a second on a rapid plate. At  $f/4$  the light, as have seen it, is perfectly steady and noiseless, and its enclosure the chamber, seen in the drawing, prevents any hot fragments the arcs falling on the studio floor. Moreover, the shield which is attached to the reflecting chamber allows of the light to be cut off in any desired way, from top, bottom, or middle, whilst the reflecting chamber itself may be directed upwards or downwards. The lamp of course, used behind a diffusing screen. It is suitable for both direct and alternating current of either 100 or 200 volts. Its price, complete with resistance stand and reflector, is £25. We should add the lamp is also supplied in a different mounting, which enables it to be placed horizontally above a velarium of any convenient size. Every agreeable diffusion of light is thus obtained, and the method of the studio being arranged so that the lamp itself is kept out of sight.

We should further add that Messrs. Griffin are showing the lamp in their professional rooms at Kingsway, and have taken a large stand at the Electrical Exhibition at Manchester, opening October 3, for the special purpose of demonstrating their Jupiter lamps. All photographers within the neighbourhood of Manchester are invited, and Messrs. Griffin will be pleased to make an appointment for them to make photographs with the lamp if they will telephone to the exhibition. The number of the stall is 252.

## New Materials, &c.

Trays and Cigarette-ash Trays. Sold by W. Tylar, Ltd., 41, High Street, Aston, Birmingham.

An ingenious and saleable novelty, particularly for the Christmas season, has been sent us by Messrs. W. Tylar, Ltd., and should be of great value to the professional photographer, inasmuch as it provides a means of supplying a photograph in a novel and attractive form. The trays are made to take a circular glass of  $2\frac{1}{2}$  inches diameter,

which is secured to the bottom of the tray by means of a thin metal plate provided with flexible tongues, which pass through slits in the bottom of the tray. Three varieties of the trays are issued, one of matt, silver-like metal, another in metal of a steel surface, and a third having the appearance of an article in hammered copper. They are issued singly or in numbers at very moderate prices.

**MR. PERCIVAL SMALL'S COLOUR PRINTS.**—We have received a small selection of these artistic productions in photogravure printed in various tints instead of the usual monochrome. The process is not new; in fact, it is almost as old as the days of mezzotint itself, and it was resorted to as an inducement to purchasers who might be refused a plate the wear and tear of which was too plainly evidenced by monochrome. Mr. Small, however, is under no such necessity, and he is to be congratulated as being practically a pioneer in the revival of tinted prints from copper applied to pro-

fessional photography. Two of these examples have already been dealt with in our review of the Royal Photographic Society's Exhibition, where they now hang. Others in the batch are perhaps hardly so successful as those. In two, an attempt has been made to give a handwork character to the portraits by introducing a background lightly drawn in black chalk. It is nicely enough managed, but its looseness and suggestiveness in no way harmonise with the faces, which are necessarily of the photograph, photographic. The portrait of Miss J. Hope as she appeared in the Chelsea pageant is, both in subject and treatment, remarkably like many a print of early days. Mr. Small, we understand, makes these photogravures for his sitters at a fixed scale of charges, and is prepared to execute commissions, on favourable terms, for professional photographers. Application should be made to him at The Tower House, 28, Tite Street, Chelsea, S.W.

**CHRISTMAS MOUNTS AND CALENDARS.**—The Crown Photographic Manufactory, Rotherham, send us specimens of their specialties of this description for the coming season. They supply a calendar mount, to take a cabinet print, slip-in fashion, for 3s. a dozen; the prevailing tone is brown, very suitable for toned bromides. The Christmas mounts are of very various designs, from an ornate design in green and gold on a cream pattern (No. 113), to a quiet chocolate-coloured card with faint white inscription (No. 71). The firm will send illustrated circular on application and sample packets of mounts or calendars at 1s., 2s., or 3s.

## CATALOGUES AND TRADE NOTICES.

**MESSRS. WELLINGTON AND WARD** have just issued instructions for the use of their bromide and gaslight (S.C.P.) papers in the form of 20-page booklets, which slip easily into the waistcoat pocket. Copies of these handy volumes can be obtained by users of, or dealers in, Wellington products on application to Elstree, Herts.

**OPTICAL LANTERNS AND ACCESSORIES.**—Messrs. J. Lancaster and Son, Ltd., Broad Street, Birmingham, have just issued a new catalogue of the numerous patterns of lantern for oil, limelight, and arc lamps placed on the market by them. The list also describes the most useful accessories for lantern work.

**LANTERNS AND CINEMATOGRAPHS.**—The first of two catalogues received from Messrs. W. Butcher and Sons is a good deal more than a price list pure and simple. It is a conveniently terse handbook on the available projection apparatus, illuminants, and accessories, the discussion of which occupies 28 pages. An abridged price list of Messrs. Butcher's many novelties for lanternists is appended. A further list of the "Empire" home cinematographs describes the use of the apparatus of this class which can be procured at such moderate prices as £4 15s. or £5 15s., that at the latter price serving for the projection also of lantern-slides.

**GOLDONIA COMPETITION.**—This competition, open exclusively to beginners and to those who had never obtained any prize in a competition before, has now been judged by Messrs. A. H. Blake and A. C. Brookes, with the following result:—First prize, James Wilkie, £3 3s.; second prize, Robert Welch, £2 2s.; third prize, Wm. E. Chetcuti, £1 1s.; commended, A. J. Johnson, 10s. 6d.

**CLASSES IN PHOTOGRAPHY.**—At the Cripplegate Institute, Golden Lane, E.C., commencing next Wednesday at 6.30 and 8 o'clock, Mr. John H. Gear, F.R.P.S., will give instruction weekly throughout the winter and spring. The courses cover a wide field of work, and should be of great value to the young professional photographer, who frequently is sadly handicapped through lack of technical training. Special attention is devoted to those wishing to gain the Technical Diplomas of the City and Guilds of London Institute and the London Chamber of Commerce. Last year over 87 per cent. of the students sitting obtained these diplomas. Pictorial work is not neglected, and those anxious to improve in this branch will obtain every facility from Mr. Gear, whose own work is so well known that no description is necessary here. From the syllabus very little appears to be omitted which is necessary for a photographer to know, whether amateur or professional, and both are admitted. Full particulars can be had from the Manager of the Institute. On Thursday evenings a very similar course is conducted by Mr. Gear at the Thornton Heath Polytechnic.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

- FRIDAY, OCTOBER 2.**  
Aberdeen Photo Art Club. Annual Business Meeting.
- SATURDAY, OCTOBER 3.**  
Wimbledon Park Photographic Society. Outing. Putney to Hammersmith.
- MONDAY, OCTOBER 5.**  
South London Photographic Society. "The Exhibition Picture." Rev. H. O. Fenton.  
Stafford Photographic Society. "Bromide and Gaslight Printing." Demonstrated. The President.
- TUESDAY, OCTOBER 6.**  
Chiswick Camera Club. Annual Meeting.  
Hackney Photographic Society. Members' Lantern Slides.  
Birmingham Photographic Society. Meeting to Inaugurate the New Rooms.
- WEDNESDAY, OCTOBER 7.**  
Edinburgh Photographic Society. "High Speed Photography." J. F. Duthie.  
Leeds Camera Club. "Old English Autumn Fair."
- THURSDAY, OCTOBER 8.**  
Liverpool Amateur Photographic Association. Lantern Lecture: "Eastward Ho!" being reminiscent of a journey to Ceylon, India and Burmah. F. Gregory Jones.  
L.C.C. School of Photo-Engraving. Bolt Court. "MS. Sources of Type and Printed Decoration of Books." G. H. Palmer, B.A.  
Wimbledon and District Camera Club. Affiliated Societies' Slides. "Tasmania."  
Northern Tasmania Camera Club.  
North-West London Photographic Society. "Architectural Photography." H. W. Bennett, F.R.P.S.  
Richmond Camera Club. "Boardoid Prints." J. Sargent.  
Handsworth Photographic Society. Competition Slides.

## Commercial & Legal Intelligence.

**THEFT BY CANVASSERS.**—At Brierley Hill, last week, John Braithwaite Ainsworth, a photographic canvasser, and Louis Lyons, both late of West Street, Stourbridge, were charged, on remand, with stealing at Kinver, on the 3rd inst., a lady's cloak, a pocket handkerchief, some needlework, and 6d. in money, the total value being £2, the property of Mary Ann Darby, of High Park Farm, Kinver. It was stated that the prisoners had both been in custody for several days, and the chairman said they were both guilty of the charge; but the magistrates had come to the conclusion, as the men had been in custody ten or eleven days, to discharge them conditionally on their entering into their recognisances to be of good behaviour, and to come up for sentence, if called upon, within twelve months. If it had not been for the fact that they had been in custody, the magistrates could not have taken that course. They were ordered to pay 16s. 1d. and costs, or 14 days in default.

**IPSWICH PHOTOGRAPHIC FAILURE.**—At Ipswich County Court, on September 25, Eustace Bernard Eldridge, photographer, 24, Butter Market, and residing at 46, London Road, Ipswich, applied for his discharge under the Bankruptcy Acts. The Official Receiver stated that bankrupt filed his own petition in March, 1903. His estimate of liabilities to rank for dividend showed a total of £306 7s. 7d., which included £200 due to his father for money lent, and a dividend of 1s. 5d. in the £ was eventually paid on proofs for £298 7s. 11d. Commencing his business life as a clerk in an insurance office, bankrupt employed his leisure time as an amateur photographer, and subsequently took up that art as a profession. He purchased a business in Ipswich, which had been carried on for some time, and was represented as being remunerative, but he was unable to make a living. Eldridge's solicitor contended that bankrupt was misled into taking the business. The discharge was granted subject to the usual two years' suspension.

**SCARBOROUGH PHOTOGRAPHIC FAILURE.**—At Scarborough Bankruptcy Court, on September 22, Joseph Edmund Bramwell, photographer, 38, Beechville Avenue, and lately carrying on business at 124, Westborough, Scarborough, was publicly examined. He stated that he commenced business at Westborough with a partner with a capital of £75. He afterwards took over the business, paying £125, which amount he agreed to pay in view of the previous year's takings amounting to over £300. The following year he took only £180, this being due to increased competition, and later he became insolvent. He had opened other places in the district, but had lost money. The creditors had refused an offer of 2s. 6d. in the £.

His wife was now carrying on the business, and she claimed no effects. An estimated account showed a deficiency of £274 0s.

**LEGAL NOTICES.**—Notice of intended dividend to the creditors of Edwin John Pulman, 11, Pontmorlais, Merthyr Tydfil, Glamorganshire, photographer, etc., has been given. The last day for receiving proofs by the Official Receiver, Post Office Chambers, Pontypool, is October 9.

Notice of intended dividend to the creditors of Scott St. Meale, photographers, etc., Coltishall, Norfolk, has also been given. The last day for receiving proofs by the Official Receiver, 8, Street, Norwich, is October 10.

### NEW COMPANIES.

**W. R. CAMERON, LTD.**—Capital, £250 in £1 shares. To acquire the business carried on by W. R. Cameron, at 100, Abbey Street, Accrington, as "W. R. Cameron," and to carry on the business of chemists, druggists, photographers, dealers in photographic requisites, etc. The first subscribers are:—W. R. Cameron, 100, A Street, Accrington, chemist and druggist; and D. Henderson, Fox Street Accrington, chemist's assistant. Private company. R. Cameron is permanent managing director. Qualification of twenty directors, 25 shares. Registered office:—100, Abbey Street, Accrington.

## News and Notes.

**PURCHASE OF OLD NEGATIVES.**—The address of the firm now Bowen, mentioned last week in reply to a correspondent, is 58, G Road, Holloway, N. This firm purchases negatives from customers within a cartage area of, say, twenty miles.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—Annual supper will be held at the rooms, on the 15th, the "A Tree and Mitre," 30, Cursitor Street, Chancery Lane, E.C. Particulars may be had from the Hon. Sec., Mr. E. R. Hurst, 43, Whitta Road, Manor Park, Essex.

**LEEDS CAMERA CLUB.**—The members' Year-book and Syllabus for 1908-9 has been issued in the shape of a convenient cloth-bound book for the waistcoat pocket. The Leeds C.C. have a full programme of fixtures.

**SOME COLONIAL PORTRAITURE** with the Dallmeyer-Bergheim has been added to the exhibits at the stall of Messrs. J. H. L. Meyer, Ltd., at the New Gallery. It is the work of Messrs. Notman and Son, of Montreal, perhaps the oldest firm of professional photographers in the colonies. The prints, done in platinum, are fine examples of powerful portraiture, which compare well with high-class work in this country.

**MR. W. ETHELBERT HENRY**, who for over twelve years past has acted as the guide and friend to those who have addressed queries to the "Amateur Photographer," has just relinquished his charge of this section of our contemporary. Mr. Henry, whose wide technical knowledge, placed liberally at the disposal of inquirers during this time, has made him many friends, some of whom hope shortly to visit in a business way on behalf of his firm, Vanguard Manufacturing Company.

**WATFORD CAMERA CLUB.**—The annual exhibition will be held at Buck's Restaurant, Watford, on October 28 and 29. In the classes silver and bronze medals will be placed at the disposal of the judge, Mr. F. J. Mortimer, for award, with the addition of a gilt plaque in the champion class. Entry forms, together with a copy of the rules and conditions governing the exhibition, may be obtained from the hon. sec., Mr. W. Branch, 100, Watford Street, Watford.

**ADMISSION TO THE NEW GALLERY BY RED BOOK TICKETS.**—The secretary of the Royal Photographic Society writes to us as follows: "The 'Red Book' was published before it had been decided to open the exhibition every evening, and in consequence the tickets in that book refer only to Monday, Thursday, and Saturday evenings. As a matter of fact, holders of Red Book tickets can obtain admission by them on any day or evening."

**LANTERN LECTURES ON LOAN.**—Messrs. A. E. Staley write: "We take this opportunity of informing your readers that we shall be

ready for exhibition before the photographic societies during the coming season a very fine set of lantern slides. These slides have been made with the Series II. f/5.6 Euryplan anastigmat by Mr. J. A. M. on a journey from Paris through Chartres to Grenoble. They may be booked starting from January 1 next."

**SOUTHERN COUNTIES PHOTOGRAPHIC EXHIBITION.**—Intending competitors are reminded that all entries close on October 5. The honorary secretary is Mr. A. D. Breeze, Great Western Chambers, Plymouth. Gold, silver, and bronze shields to be awarded this year are for the best excellent design and workmanship, and should be highly valued by the successful winners.

## Correspondence.

We do not undertake responsibility for the opinions expressed by our correspondents.

Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

### THE PICTORIAL WORK OF TO-DAY AND FIFTEEN YEARS AGO.

To the Editors.

Gentlemen,—I, for one, believe that "Anti-progress" is not in vogue in his preference for "straight" as distinguished from "coloured" photography. Curiously enough, Mr. Mortimer, one of the oil-prints "Anti-progress" holds up as an awful example, is remarkable in last week's "Amateur Photographer," apropos of B. Gay Wilkinson: "One of the most consistent of the 'old school' of landscape workers, of whom J. B. B. Wellington and the late Mr. J. A. M. were shining examples. We see too little of Mr. J. A. M.'s pictorial work nowadays, and the exhibitions are the result of the absence of his straightforward outlook on Nature." It thus appears that your critic's comparison with the "old school" of work is not such an important qualification of his praise for the oil-prints and Co.-cum-Ponting exhibit at the Royal as "Anti-progress" would have us believe.—Yours truly,  
K. HICKS.  
1, Elmiston Road, Shepherd's Bush, W.

To the Editors.

Gentlemen,—Although gum and oil printing do not come within the scope of your publication—to use the term you have been good enough to use—the Raines Service, yet we are only too pleased to accept of mounting and framing prints made by either method. We are because we are afraid that "Anti-progress," in his vigorous attack on "straight" photography, may have given offence to some of the workers in the "control" processes, and naturally we do not wish to be identified with any such methods of discussion.—We are, gentlemen, yours faithfully,  
R. AINES AND CO.  
Photographic Works, Ealing, London, W. Per W. J. Casey.

### REMINDER TO PROVINCIAL PHOTOGRAPHERS.

To the Editors.

Gentlemen,—The season for municipal and most of the various functions of the Borough and County Council, and all functions in local government life, is approaching, and it behoves camera men to be busy in securing sittings from present and prospective councillors in particular—candidates, etc., within their respective areas.

"Free portrait" non-ratepayers are on the warpath with deductive circulars—no charge for sittings either at home or at the best End studio. Such invitations are being sent broadcast to public men in the provinces, all over Great Britain, with a view to the effect that they would be prepared also to photograph members of the official's family at a special rate, with even a fee, if not approved, all without fee. These invitations are sometimes by three or four differently worded blandishments, and no answer should be received to the circulars. Masters of schools and colleges are canvassed for groups of the boys and girls, and of view books and postcards.

Provincial photographers, be up and doing! Canvass in your own area where you assist with your contributions to the rates, and in your business in your own hands, as far as possible. So we may mind our brothers to be active.  
V. S.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 2A, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 2A, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 2A, Wellington Street Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

- T. Cummings, 4, Clarence Terrace, Stockton-on-Tees. Photograph of the Stockton and Thornaby Surgical Hospital.
- W. C. Hampton, 21, Esplanade, Largs. Photograph (Combination) containing Five Views and entitled: "Photograph of Peeps of Greta Falls, Largs."
- E. O. Parkin, 68, Wilkinson Street, Sheffield. Two Photographs of Sheffield United Football Team, 1908-9.
- T. W. Marshall, 55, Box Lea Terrace, Thornaby-on-Tees. Photograph of Lady Bell's Rest House, East Rounton, Northallerton, Yorkshire.
- Miss G. S. Kirkby, Lansdown, West Kirby, Cheshire. Photograph of West Kirby Parish Church after a Snow Storm.
- Yorkshire Speleological Association, 317, Roundhay Road, Leeds. Nine Photographs of Gaping Ghyll, Yorkshire.

### DRAWING REGISTERED:—

- H. L. Morel, 126, Welbeck Terrace, Mansfield Road, Nottingham. Drawing entitled: "Nottingham Goose Fair Souvenir, 1908."

**SWING FRONT.**—Can you kindly let me know whether the action of a swing front fitted to a studio type of camera is in all respects the same as a swing back, and if not, in what points does it differ from the latter? Your reply would be exceedingly valuable if you can deal fully with the matter, as I know others of your readers who are anxious to obtain information upon this subject.—  
INQUIRER.

The swing front is in all respects a perfect substitute for the vertical swing back, provided the swing front is combined with a rising and falling front with a big range of movement; but, of course, a vertically swinging front will not take the place of a horizontal swing to the back. Seeing that in studio work the swinging movement is only required for purposes of focussing, we are inclined to think that the swing back is preferable for studio work. A universal swing front would be a perfect substitute, but it would be difficult to manipulate with a big studio camera. With field cameras the conditions are different, and the swing front is undoubtedly the easiest to manage.

**HYPO.**—We do not know who are the makers of such apparatus. Dealers in bookbinders' requirements might supply it.

**SQUEEGEED PRINTS.**—As I have had much trouble to get prints off the glass after squeegeeing, I have treated them in the following way. After the prints have been dried, I have soaked them in a solution of 1 oz. formaline in 10 oz. of water for about 5 minutes and then put them on the glass without washing, and the result has been every print came off clean and beautiful, without any trouble. Will this treatment cause them to fade or discolour afterwards or interfere with their permanency?—  
NOVICE.

There is no reason to think it will, though we must say we should prefer to wash for at least two minutes. This should not affect the ease of stripping.

**READER.**—Without a knowledge of your requirements it is impossible for us to say. It is for you to choose between gas, arc-light, or mercury vapour. Your best course is to send for price lists of makers of the lamps. See our advertisement pages.

**DEVELOPER.**—Could you please inform me through the columns of your paper of a good formula for density of negatives taken by electric light. At present I am using hydroquinone and caustic soda, which gives a nice soft negative with no density to speak of.—  
MAS.

Your experience is quite exceptional. Hydroquinone easily

gives a very hard negative, owing to its short multiplying factor. There must be something wrong with the formula you are using or the exposures you are giving. Try the second formula on page 787 of the current "Almanac."

**OWNERSHIP OF NEGATIVE.**—Kindly inform me to whom does the negative belong? 1. If I am requested to take a photograph and paid for copies thereof. 2. If I ask permission to take a portrait and copies are afterwards wanted and paid for.—ENTHU.

1. The negative is the property of the sitter, but you are entitled to retain custody of it. 2. The negative is yours without qualification.

**FIXATIVE FOR PASTEL WORK.**—Can you tell me if it is possible to fix pastels to prevent rubbing. Would ordinary fixative do, as used for black and white?—ARTIST.

The fixative given for crayon work can also be used for pastel. You will find the formula on page 837 of the "Almanac."

**COPYRIGHT.**—A friend of mine asked me to take a photograph of his family in their garden, which I have done and copyrighted same, also giving them two copies free of charge. A friend of theirs now says he is going to send one of the prints away to have it copied and enlarged by the free coupon dodge. 1. Can I stop him from doing this? 2. If he does, what redress can I claim? 3. From whom should I claim?—EDWARD PLOWMAN.

1. You cannot restrain him for doing what he suggests, but his act is an infringement of your copyright in the photograph. 2. You can take action and recover penalty for infringement provided that you register the copyright prior to the alleged infringement. 3. You can proceed either against the friend or the enlarging firm.

**ENQUIRER.**—So long as you do not sell scheduled poisons you are at liberty to trade in chemicals. The photographic chemicals which you should avoid are potassium cyanide and mercury chloride, and you must not sell mixtures which contain either of these bodies, even though their presence may not be known to you.

**DEVELOPED WARM TONES.**—1. Will you kindly inform me in the next issue of the "Journal" whether there is any really practical and easily worked formula for the obtaining of purple-brown tones, similar to those obtained by hypo-alum, by direct development of bromide paper? 2. Also, can you supply the name of any firm who prepare composite designs for use in making peeling and other cards by combining several views on the one card?—W. L.

1. We know of no method which approaches the after-toning processes. 2. If you mean a special design we can best refer you to an artist and designer such as Mr. W. T. Whitehead, 10 and 11, Fetter Lane, E.C.

**COLOUR PHOTOGRAPHY.**—You will greatly oblige me by giving directions for converting a black tone positive into a bluish-green one, fit for use as a component of a trichromatic transparency. Also please state what advantage there is in using such a component instead of a gelatine relief positive stained to a bluish-green colour.—TRICHROME.

The developed positive may be bleached in a 10 per cent. solution of potass ferricyanide, washed and placed in ferric chloride solution until the desired tone is reached, or an alternative bath is:—Ammonium ferric oxalate, 8 grs.; potass ferricyanide, 8 grs.; glacial acetic acid, 80 minims; water, 3½ ozs., which tones the developed positive directly to a blue. The colour is afterwards given a greenish tone by immersion, after washing for one or two minutes in a 1 or 2 per cent. solution of hydrochloric acid. This blue is not as close to theoretical requirements as can be secured with a dyed relief, and the latter method is therefore more satisfactory.

**J. T.**—We can only suppose they are by the well-known firm of Valentine, 154, Perth Road, Dundee.

**S. PORTER.**—We do not recognise the name, unless you mean M. Klary, 17, rue de Mauberge, Paris.

**S. E.**—So far as we know, there is nothing exceptional in the method of working of the gentlemen named beyond the skill they bring to bear upon it. You can avoid the extreme whiteness you get on the foreheads of your portraits by the judicious use of a head screen. If you use a cream bromide paper we should think that

any after-staining would be unnecessary—if you pay attention to the lighting. You might try staining the pictures with an infusion of coffee.

**LENS CAP.**—In our next.

**SULPHIDE TONING.**—(1) Will you please inform me which you consider the better method for obtaining sepia tints on bromide, the hypo-alum or sulphide? I have tried the latter, but, far, have not been very successful. I shall be pleased to receive your advice. Also, will you give formula for both? (2) I know of any substance that will colour matt varnish so as to make it more opaque?—A. BRUCE.

(1) Some few papers will not tone well by the sulphide process, but if you use a make for which sulphide toning is recommended, you should have no difficulty at all. The normal formula of ferricyanide and bromide, followed by sulphide, is quite satisfactory. If you have had any difficulty you had better try again a made-up preparation for the purpose. (2) Malachite green, aurantia, or asphaltum.

**PRESS PHOTOGRAPHY.**—(1) Do Press photographers, either on the staff of a paper, an agency, or unattached, receive railway passes for the various railway companies? If so, to what official should application for a pass be addressed? (2) In the case of such passes as sports, race meetings, demonstrations, etc., is it usual for the Press to send photographers to order photographs from the agencies, or do they purchase photographs which are submitted after the event is over? (3) Do any of the Press agencies make a special feature of using photographs (of news events, etc.) by men not on their staff? (4) What are the addresses of the Press Illustrations Bureau, (b) London News Agency, (c) World's Geographic Press, (d) Topical Press?—X. PRESS.

(1) So far as we are aware, they do not. Why should they? They may have an understanding as to having the first refusal of work of a given agency or Press photographic firm, but it is for the agency employing photographers or a firm of Press photographers to offer their work round the papers, some of which may advise beforehand. (3) Rarely of subjects with which the own staff can deal, for the reason that the agency has earlier secured the rights of an unexpected event than publication in the newspaper therefore has always some hours' start of the unattached photographer. (4) (a) We do not know; we believe the firm is (b) 173-5, Fleet Street, E.C. (c) We do not know. (d) Outer Temple, E.C.

**NEMO.**—From what we gather from your letter you have secured a mild term—acted very discreditably, and now you seem surprised to find yourself in an unpleasant position, and ask us to tell you how to get out of it. That we must decline to do, and refer you to a solicitor.

**H. C. G.**—If the patent to which you refer has lapsed you are at liberty to work the process. We do not know whether it has or not. The full term of fourteen years has not yet expired, but that is nothing to go by. If the annual renewal fees have been kept up the patent has lapsed, and you can work the process without let or hindrance. If you refer to the register in the Patent Office you will see how the patent stands.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received only on the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

BRITISH JOURNAL ALMANAC—PAST AND PRESENT ..... 775	

## SUMMARY.

The "B.J. Almanac" past and present. Apropos of the completion of the "British Journal Almanac," 1909, for the press in a fortnight's time we publish some notes on the first "Almanac," that of the year 1861. (P. 775.)

F. Dillaye has published lengthy details of the making of prints via bromides by the bromoil and ozobrome processes. Methods would appear to have no great advantage over that of Mr. Welborne Piper, but there are one or two useful suggestions. (P. 768.)

C. E. K. Mees, in the further chapter on the photography of coloured objects, deals with light-filters and the absorptions they would have for orthochromatic photography. (P. 770.)

A. Lockett contributes a description of the calculator for use in the work at present being shown at the Royal Photographic Society's Exhibition. (P. 773.)

The art editor of the "Daily Mirror" gave a confidential talk on press photography to the students of the Bolt Court School last week. A report appears on page 774.

Igorous carbon transparencies. Some editorial notes deal with intensifying method which may be employed in producing extra pur in the carbon transparency. These are based on the staining and similar treatment of the gelatine relief. (P. 767.)

Neglect of the cleaning of the incandescent gas burner is a frequent cause of complaints when using this illuminant for enlarging. (P. 766.)

A few notes as to the making of a dead-black background are given on page 766.

The Lumière Brothers have investigated the use of thiocarbamide as a substitute for hypo in combined baths, and conclude that there is not much to be said for it. (P. 776.)

Our report of the "great congress" of photography, the counting seconds, and the invention of self-toning paper figure under correspondence. (P. 781.)

Some specimens of photographs taken with the "Thames" screen-plate have been added to the exhibition of the Royal Photographic Society. (P. 765.)

## EX CATHEDRA.

**The "Thames" Plate at Last.** The colour section at the New Gallery has been reinforced during the past week by four specimens of the long-expected Thames plate, and the results are certainly very promising. The quality of the four transparencies is rather variable—one is a poor result while two are certainly good. The colours are brilliant and very transparent, and transparency is an obvious advantage in some respects. It has, however, yet to be proved whether transparency can be attained without loss in other directions. The beautifully soft greys and browns obtained on the Autochrome may depend somewhat on its want of transparency. They are rare in other colour processes, and it will be interesting to see if any other screen-plate will represent them as well as does the Autochrome. The Thames plates are on view in the gallery devoted to the technical section and portraits belonging to the R.P.S. collection.

\* \* \*

**The Dresden Exhibition.** But comparatively little time remains before the arrangements for the allocation of space to British firms in the "Trade" section of this international exhibition must be made. From all we can hear, the exhibition will be organised on a most comprehensive scale, and may be expected to attract visitors from all countries, and large numbers from photographic circles in this country and across the Channel. We learn from Mr. Martin Duncan, through whom arrangements may be made as to position of and charges for space, that the German authorities are prepared to erect a special pavilion solely for the British firms in the event of the collected exhibits of these latter reaching a certain amount. Mr. Duncan should be addressed at 39, Bradeley Gardens, Ealing, W., for further particulars.

\* \* \*

**Colour in Autochromes.** A writer in a contemporary criticising the Autochromes at the Salon, while admitting that the Autochrome is fairly satisfactory in its representation of primary colours, asserts that it is less satisfactory in the secondaries, and in the tertiaries it absolutely fails. Last year, when the Autochromes were first exhibited at the New Gallery, a well-known painter of great repute expressed admiration for the manner in which the Autochrome represented tertiary colours, and this year many of the slides at the New Gallery prove beyond all dispute that greys and browns can be rendered most perfectly. Evidently the critic to whom we have referred has been misled by the Salon display, in which primaries play a very prominent part. It is, however, a pity that the crudities at the Salon should lead to the Autochrome being libelled in this way, for, as a matter of fact, its

powers in the way of rendering tertiary colours and the subtleties of subdued colour are very great. Yet it is not so easy to make the plate reveal these powers as it is to produce startling effects of strong colour. Correct exposure is essential in the one case and errors are easily detected, whereas in the other case incorrect exposure that gives wrong colours only adds to the startling character of the result. In built-up still life studies the colours may be considerably varied without the errors being detected if the original is not available for comparison; but Nature is always available, and careless colour representation of her colour schemes will not pass muster. A study of M. Belhazy's work at the New Gallery will give a good idea of what the Autochrome is really capable of doing in the hands of a careful worker and trained observer of colour.

### Carbon Printing Output.

We are frequently asked, usually by some photographer who has just taken up carbon printing in his business, what is a fair output for a printer. Of course, it is impossible to give an answer off-hand, as so very much depends on the quality of the negatives and whether they are reasonably uniform, and also on the quality desired in the finished prints. It is clear that if there are not many negatives, and these are excessively dense, a good deal of time will be spent in waiting, even in a fairly good light. On the other hand, given an even batch of negatives of the right printing quality, there is little limit to the number of pieces of tissue which may be exposed, provided the negatives are carefully classified and marked with the proper actinometer tint to begin with. When the negatives are right then the limitation to the day's output is found in the putting down of the tissue on the supports and the development. If a printer stops work at six he must find out by experience how long he can go on exposing tissue while leaving sufficient time to get his prints developed before that hour. Starting at nine, and with plenty of negatives, he may easily print by the middle of the day more pieces of tissue than he will be able to develop during the afternoon. Taking cabinet pictures as being the most usual size, we should regard four or five dozen prints of first-rate quality a very fair day's work for a printer who had to classify some of the negatives and give many of them the humouring necessary to obtain the best result. If all the negatives had previously been in print and their requirements were known, and assuming reversed negatives from which single transfer prints could be made, it might then be possible to increase this output very considerably, in fact, to an extent considerably dependent on the bench and developing tank accommodation.

It is, of course, unfair to expect a large output if a tin dist. and an ordinary kettle are the only utensils available for the work of development.

**Dead Black Backgrounds.** A correspondent recently wished to know of a simple method of preparing a dead black background, and we recommended him to try the powder process, which is very effective. A quicker way that involves no special preparation is useful at times, and we have found the following very convenient and effective. Take a frame or strainer covered with linen or the "sheeting" commonly used, and, omitting sizing or any preliminary coating, wet it well all over and then coat both sides with a water-colour paint composed of lamp-black gum, and water. Fine ground lamp-black as supplied by artists' colourmen should be used, and we prefer to purchase it dry, though it can be obtained already ground in water. The oilshop ordinary lamp-black is generally too coarse to be of any use. The best mixing tool is a big brush, a house-painting "tool," and the powder and gum should be added to the mixture in small quantities, no more powder being added until the previous lot is reduced to a paste. About two ounces of ordinary "office gum," or a strong solution of gum arabic, and about eight ounces of water will make enough paint to give two coats on both sides of a 3ft. by 2ft. strainer, enough lamp-black being used to give the required consistency. Two or three thin coatings give a better result than one thick one, and it will be found that each coat dries very quickly in a draught. This is practically the same thing as a water-colour pigment, and it is just as effective on paper as on linen. The strainers are, however, very useful things, and it is always advisable to have a few handy for coating with any colour desired. The paint can always be washed off if a background of a new colour is required. The linen used for covering the frames should be tightly strained over them and put on in a very slightly damp, but not wet, state. If not tight enough it will become badly distorted and buckled when painted.

**Incandescent Gaslight.** Though the incandescent gaslight is almost universal use, it is not very common to see proof of the little care which is taken to secure the best results from it. One or two hints of a strictly practical kind may be given for the benefit of those readers who are not above taking them. Whenever a new mantle is put on, the whole burner should be brushed with a stiff clothes or similar brush. The small holes through which the gas is distributed should always be kept open. The proportions of gas and air must be correct. In most cases the air supply is too great.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1909.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-eighth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of over 1,000 pages, and the entire edition of 25,000 copies was sold out immediately. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1909 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

### REFLEX CAMERAS,

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1909 will be

modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1909 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and, wherever practicable, new features of an informative nature will be added.

**\*\* NOTICE—IMPORTANT.**—Our publishers ask us to notify intending advertisers that in order to complete the hundredth edition of the ALMANAC (25,000 copies) for simultaneous publication on December 1, it will be necessary to close the pages a week hence; therefore, the latest date for receiving orders and copy will be Friday, October 16.

is a regulating collar things are easily remedied by spring or uncovering the air holes until the best light is reached. In default of the collar the hole or holes should be temporarily covered by the finger. When the effect is not stamp-edging or court-plaster can be used to stop the holes not required. If, however, the light is not proved in this way the gas supply is insufficient and the holes in the nipple should be enlarged. A stout file will usually do this, but should be used carefully, as very little enlargement is required. Should one inadvertently make the holes too large, the slight burr on the underside should be smoothed out. Some "Bijou" burners we so treated gave in place of a glimmer an excellent light. When several lights are on an inadequate gas pipe these little burners will be found to consume a minute quantity of gas with a better result than a large burner. For decorative effect they are excellent. On the subject of gas appliances it may be mentioned that the yellow flame of the gas-ring, much used for carbon printing, can be put right simply by cleaning the burner thoroughly. Usually the gas company will clean such burners without charge.

#### ROUS CARBON TRANSPARENCIES FROM WEAK NEGATIVES.

It is tolerably well known that in reproducing negatives, whether of the same size or enlarged, the results depend much upon the character of the transparency from which we start. If this be thin and feeble the enlarged negative will be poor and flat, for it is next to impossible to obtain vigorous negatives from flat transparencies by any system be followed. At the present time it is generally admitted that the best transparencies for enlarging negatives are those by the carbon process, this method is almost universally employed by professional enlargers who work by way of enlarged negatives. One of the reasons for this is that there is a more perfect definition in the carbon image than is usually got in a silver

In the silver picture we have only the silver forming the image in a perfectly even layer of the vehicle holding together that be gelatine, collodion, or albumen. In the carbon image we have not only the pigment, but also its different thicknesses of the vehicle—the gelatine.

The pigmented film is thin in the lights, indeed, in the extreme high-lights there is practically no film at all, in the shadows and darkest parts it is of considerable thickness; so that the gradation is due not only to the density, *per se*, but also to the varying thicknesses of the film which carries it.

It is very generally recognised that the best negatives for carbon printing are those of a vigorous type. The light then penetrates somewhat deeply into the tissue in the shadow, and a considerable thickness of the gelatine is rendered insoluble in the darker parts of the picture. As a matter of fact a carbon picture is in reality a relief in the negative—plus a pigment. This may often be seen in the prints made from strong negatives, but a more pronounced relief is seen if the picture be developed on a support such as a glass plate. But if the print is made from a thin and poor negative the relief will be but slight, and as a consequence the print will be feeble in making its contrasts. This, however, may to an extent be overcome by modifying the strength of the sensitising solution, yet it may not be known to every one that carbon transparencies can be intensified by different methods. Intensification is, in principle, quite different from that of the intensification of silver images. In the carbon it is the pigment forming the image—i.e., the silver—acted upon, but in the former it is the vehicle hold-

ing the pigment (the gelatine) that is acted upon and not the colouring matter. That being the case, it is manifest that the greater the thickness of the gelatine the greater will be the intensification obtainable. Therefore, when dealing with feeble negatives the object should be to get a high relief in the image, and this is the point that will now be dealt with.

For making transparencies from negatives of, we will say, an average type, nothing can be better than the special transparency tissue made for the purpose. But for very feeble negatives that require to be intensified afterwards it is not the best, since, in consequence of the large amount of pigment it contains, the light cannot penetrate deeply into the film. With such tissue there is always very little relief. If two prints be made from the same negative, the one on the "special transparency" tissue and the other on one with little pigment, such as some of the portrait tissues, and if the two be developed on glass, it will be seen that the one, though dense in the image, has little or no relief, whereas the other will be more or less in high relief, though it will not be so dense as regards colour. Seeing that it is only the gelatine that is acted upon by the intensifying agent it will be obvious that the one with the strongest relief is the one that will yield the densest picture when intensified. If the two pictures be now put into a solution of permanganate of potash, which is the simplest, and at the same time the best intensifier, for a few minutes, and then washed, it will be found that the thinner print has gained considerably in density while the other has changed but little. If the permanganate is allowed to act for longer the thinner transparency will go on gaining in depth, while the other will remain very much as it was at first, and in the end the thin picture will become the stronger. The strength of the permanganate solution employed is of very little moment—the stronger it is, the quicker is its action; ten to twenty grains to the ounce of water is a good proportion to use.

From what has been said it will be recognised that as the high-lights of a carbon transparency are, practically, bare glass, there is nothing in them to intensify; hence, within certain limits, any amount of vigour may be obtained by intensification—in fact, far more than is ever required in practical working.

Only the permanganate of potash has been mentioned as an intensifier, but there are several others that can be used, and various colours obtained. For example, if the transparency be put into a one per cent. solution of nitrate of silver until the film is thoroughly permeated, then slightly rinsed, and afterwards flowed over with the ordinary acid pyro developer (as used in the collodion process), with a few drops of nitrate of silver solution added, the picture will be intensified, and be of a pleasing warm brown tone suitable for lantern slides. If the transparency be immersed in a solution of a salt of iron, say, the perchloride, then rinsed, and afterwards treated with a weak solution of gallic acid, a strong velvety purple-black will result. By varying the iron salt, and following it with pyrogallol acid, infusion of nut-galls, logwood, etc., a great variety of tints may be obtained. By first treating the transparency with a solution of bichromate of potash, and then with one of acetate of lead, a yellow colour results, owing to the formation of the yellow chromate of lead in the film. Many other colours may be obtained by means that are analogous to those employed in the dyeing of fabrics.

DEATH OF A HEANOR PHOTOGRAPHER.—At Heanor last week Mr. Abner Grainger, aged 58, residing at 16, High Street, was found dead in the dark-room of his studio. It appears that the deceased had been suffering from heart disease.

## ENLARGEMENTS IN "OIL" BY THE BROMOIL AND OZOBROME PROCESSES.

[The following article by M. F. Dillaye, in which is described the writer's work in oil enlargements, appears to be written in ignorance of the work of Mr. Welborne Piper in this country and of his first publication of these processes in the "Photographic News." M. Dillaye's full text, which we slightly abridge from "La Revue de Photographie," does, indeed, refer to the cognate work of Mr. Howard Farmer, but not to the more recent English publications.—Eds. "B.J."]

THE first operation in the use of bromide prints for the oil process consists in the application of a bath of bichromate after development. As to the use of a fixing bath immediately following, it would appear that such a bath does more harm than good. On the one hand, if by fixing we remove the undecomposed silver bromide contained in the gelatine film corresponding to the portions not affected by the light, we produce a great decrease in the volume of the gelatine film. This decrease of volume can be experienced only in the direction perpendicular to the plane of the paper, seeing that the film is in strong adherence to the paper, and will be so all the more as the silver image favours its adhesion. On the other hand, if these same unaffected portions have lost little or much of their elasticity in the course of development, owing to the fact of the developer forming a trace of oxidisable matter by direct contact with the air, there will be fissures to a greater or less extent, and the contraction due to the bichromate will not be even. For this reason it is better to keep the enlargement unfixed before subjecting it to the action of the bichromate bath.

It next remains to decide whether, the film having been bichromated, it should be immediately bleached or first allowed to dry. Experience certainly points to the choice of the second alternative. On drying the film in diffused light the film closes up and the bichromated image appears to sink more intimately into the gelatine. We are thus led to the following *modus operandi*:—The bromide enlargement is carefully developed with a solution not liable to oxidation, such as metol or diamidophenol. The print should be perfectly clean without a trace of veil or fog—that is to say, with all detail in the half-tones and high-lights, and with no choked-up shadows. It is not necessary that it should be as vigorous as if it were to be kept as a bromide, but it is important that it should be a fogless print of a full range of gradation. After development the print is well rinsed from all traces of the developer, and placed in a dish containing a saturated solution of potassium bichromate or ammonium bichromate—no appreciable difference can be discovered between the two salts. Here it is left for from five to ten minutes, according to its strength. If, through incorrect development, it has been obtained too strong, it may be left in the solution for fifteen minutes. The print is then hung up to dry after attaching to its lower edge a strip of papier Joseph in order to draw off the excess of bichromate solution and render the drying more regular. It must be borne in mind that, as the print is still unfixed, all these operations must be performed in the yellow light of the dark-room.

The print having dried, it is placed, still in the dark-room light, into a bleaching solution, either of lead ferricyanide or potassium bichromate and hydrochloric acid. The respective formulæ are those of Eder and Toth, and are as follows:—

### Lead Ferricyanide Bleacher.

Lead acetate .....	4 gms.
Potassium ferricyanide .....	6 gms.
Water to make .....	100 ccs.

### Bichromate Bleacher.

Potassium bichromate .....	10 gms.
Hydrochloric acid (pure) .....	30 ccs.
Water to make .....	100 ccs.

The latter is preferable to the former, and is the one which I

employ exclusively. Bleaching takes place very quickly, almost instantaneously—in fact, quite instantaneously if the print has not been dried between bleaching and immersion in its bichromate bath.

The bleached print is put in running water to wash until a trace of bichromate is removed and the print is perfectly white. This requires about fifteen to twenty minutes; and when the state of the print has been secured, the latter is fixed for about ten or fifteen minutes in a 10 or 15 per cent. solution of hyposulphite or in a 15 per cent. solution of ammonia. It is then finally washed in the usual way, and is ready for inking either immediately or after drying.

A hint as to whether the insolubilisation of the film has been partial or complete in the different manipulations may be gained by gradually raising the temperature of the wash water to 30 or 35 deg. If the image swells enough to show all the details of the relief of an etching, it is certain that it will take the ink in the after-process.

All the experiments made so far show that it is not possible to exceed a certain degree of inking, namely, one more than is sufficient for oil work by those who use muslin, rubber, or eraser, but not enough for those who wish for a facsimile of the negative with the minimum of intervention by hand. It would appear that inking, after being pushed to a certain point, cannot be taken any further whatever one may do. The ink which is applied comes off in the cleaning-up, whatever kind of ink is used, and that of a soft kind is more commonly used than hard. I cannot say whether this is due to the thinness of the gelatine film or to some other cause. Before saying more on this point I must come to the alternative method of preparing an enlargement from a bromide enlargement by transfer.

The so-called double transfer papers are obtainable in greater variety than bromide papers, and I judge that even when they are coated they contain more gelatine than bromide papers. Moreover, the method which has just been described gives only one print from the bromide enlargement, whilst by working by transfer a number of copies can be made, as in the ozobrome process. This latter process has already been suggested by M. Puyo, and possible means of preparing a surface ready for pigmentation. M. Puyo has also confessed his inability to employ it successfully. The failure would appear to be due to the lack of information on the preparation of the bromide print, the composition of the bleaching solution, and an exact method of procedure. All bromide prints are not suitable for the process. It is sometimes necessary to modify the composition of the bleaching solution, and there are certain practical items in the working method which should be adopted.

In order that a bromide should give a good transfer—the same may be said, for the oil process—it is necessary that it should be pressed deeply into the gelatine of the transfer paper. This kind of transfer is given by a bromide in proportion to its own gradation embraces a wide range of silver deposit, and secure a print of this kind a particular manner of development has appeared best to me. It may be called a step-by-step method (*développement par étapes*).

The enlargement is made on a vigorous brand of bromide paper—say the Lumière B—and a sufficient exposure given for the parts of the negative, which latter is placed in the carrier, to be wrong way round. It is then placed in clean water to render flaccid, the water poured off, and a developer of acid diazo

enol poured over it. The formula may be that recommended Balagny for papers, or one of the numerous others.

In working with papers without a tendency to curl, this preliminary soak is not necessary; in fact, it is best to dispense with it when the paper will permit, and apply the developer to dry print. For in this case the developer will at once penetrate the gelatine film, and, as I will mention in a moment, will the production of a suitable silver image.

As soon as the outlines of the image are seen in shadowy action, scarcely perceptible on the paper, which should be for two or three minutes' immersion, the developer should be poured back into the measure and the print rinsed under tap for an instant, in order to remove the developer adhering to the surface. The dish containing only the wet print is then stood on one side, and the image allowed to continue to develop only by means of the developer retained on the gelatine. At the end of a certain time the whole picture appears, but still weak and pale. The print should now be placed again in the developer, the latter allowed to act for two or three minutes, again rinsed off, and development continued as before by means of the quantity of reagent retained on the gelatine. Thus step by step a perfect image regarding details, values and total strength is built up. The process can be readily followed by holding the print up to a dark-room lamp, as when developing a negative. The use of acid amidol allows of this being done without fear of veil. The print is fixed in the usual way, employing for preference a neutral bath as generally directed for the ozobrome process.

It is a good plan to pass the fixed print, whilst still saturated with the hypo solution, for a few seconds into a weak ( $\frac{1}{2}$  to 1 per cent.) solution of potassium ferricyanide, only to lighten it, but to ensure the absence of any veil in the high-lights, which, despite the intermittent washings, might have been caused during development. The total absence of deposit on what should be a pure high-light is of the greatest importance. It is then washed in the ordinary way, and placed to dry.

The transference of the picture to a double-transfer paper, "Fer à cheval," is done as follows:—

To 1 litre of water 1 cc. of pure nitric acid is added.

The following separate solutions are prepared:—

	Mix in the proportion of	Add water in the proportion of
ss. bichromate, 6 per cent.	5	5, 10, or 15, according to the effect desired or time of contact.
ferricyanide, 9 per cent.	5	
bromide, 6 per cent. ...	5	
potash alum, 5 per cent. }	-5	
acetic acid glacial, 2.5 cc. }		

The bromide print is plunged for a few moments into the nitric acid solution, and the surface lightly gone over with a swab of cotton wool, with the object, if the washing has not been absolutely complete, of destroying any traces of hypo. This elimination of hypo is important, since the fixing bath contains ferricyanide, which, with the least trace of hypo, would form a reducing mixture, and would prevent the ink to take irregularly.

Thus cleaned, the print is washed free from acid by immersion for five or ten minutes in clean water.

The oxidising bath given above is then poured on to the print, either as above given or diluted. The proportion of alum given above is an average, and answers in the majority of cases, but it can be varied from .2 to 1. The more the proportion used, the more active is the action of the solution in preventing the diffusion of the chemicals into the body of the film, and therefore the finer and cleaner the results. A very weak oxidising bath produces the same results as a stronger bath if the time of action is sufficiently prolonged, and it is an advantage in the case of large prints to employ a weaker solution for the sake of its evenness of

action. It may be said that if a bath used neat required fifteen minutes for its action, dilution five times will mean that it must be used for half an hour, a dilution of ten will entail a time of one hour, and a dilution of fifteen, two hours (other things being equal) to produce an identical result.

6. Before proceeding to immerse the double transfer paper in the oxidising bath, a piece of stout white blotting-paper, a little larger than the double transfer paper, should be placed in a dish of plain water so as to absorb water fully, and be then hung up to drain.

7. The oxidising bath being at a temperature of about 15 deg. C., or lower (10 deg. C.), if possible, the double transfer paper is immersed, avoiding air-bubbles, and allowed to remain for four or five minutes or more. The bath is then returned to the bottle, leaving the double transfer paper, well drained, on the bottom of the dish to absorb all excess of liquid.

8. During this time the bromide print is withdrawn from the water and laid flat on a sheet of glass, gelatine side in contact with the glass. The back is then firmly and evenly pressed with a squeegee to express the excess of water as completely as possible.

This and the preceding part of the process—viz., the complete absorption of the bath by the paper—should receive careful attention, since it is found that much better contact is made when there is no unabsorbed liquid on the two surfaces.

9. The bromide print, having been thus surface-dried, is removed from the glass plate, which is quickly cleaned, and the bichromated paper then laid upon it, gelatine side down. The bromide print is then gently lowered upon it, film to film, by first placing the edges in contact and then lowering the other portion. A few passes of the roller squeegee are then given to make the contact good.

10. The sheet of white blotting-paper, which has been draining during this time, is now taken and laid upon the whole, and caused to adhere with a stroke or two of the squeegee. The object of this last application is twofold: First, the oxidation of the gelatine takes better when the papers are damp; secondly, the blotting-paper provides an excellent means of judging of the period of contact necessary.

At the end of a certain time the white blotting-paper over the whole area corresponding with the bromide print becomes of a pale yellow colour, the depth of the colour increasing with the time of contact. As soon as the tint appears, it is certain that the bromide print has been penetrated by the bichromate bath, a point which corresponds with full exposure in the ordinary oil process. The longer the tint is left to deepen, the greater the degree of "exposure." Those who prefer to work with a full- or under-timed exposure in the ordinary oil method can consult their preferences when working by the above plan, and will soon learn to recognise the point at which to arrest the operation.

11. When the period of contact comes to an end, the blotting-paper is removed, and the bromide print gently raised and placed away by itself. There is usually no difficulty about this, owing to the moist state of the papers, but should there be any, the two papers should be placed for an instant in cold water, and then stripped apart. In all cases the bromide and transfer paper should be placed in separate lots of clean water, and there washed until completely deprived of the bichromate. It is a good plan to use tepid water for this purpose (30 deg. C.). The bichromate is removed more rapidly and the image swells more strongly than it otherwise would, so much so that it presents the appearance—it is all the better for this—of an etching.

If, in the case of a large print, the aim is to produce a certain granular effect, the print, on coming out of the warm water, should be dipped in quite cold water, or left to soak therein for a time. When thus chilled the gelatine instantly reticulates and becomes covered with a small, fine, regular grain. The dodge may be made use of in some cases.

The bichromated print having been perfectly cleared of yellow stain, may be pigmented at once, or put aside to dry for nigmenting at a later time.

As for the bromide, much, little, or none of which may be visible, it is re-developed in full daylight, and will be thereby restored to its original condition. After washing, it is ready for a repetition of the process.

The above operation, if carefully carried out with a bromide

print without fog and free from every trace of hypo, permit of as ready inking of the transfer paper image as when the surface is prepared by direct exposure to light. If contact has been very prolonged, the only ink which is suitable is the very hard No. 1 ink of Lorilleux, which must therefore be mixed with some soft copper-plate ink, and frequently this latter alone is the most suitable, and works well without medium.

FRÉDÉRIC DILLAYE

#### MR. WELBORNE PIPER ON THE ABOVE SUGGESTED METHODS.

M. Dillaye's methods of preparing prints for pigmenting are very interesting, but it is, I think, apparent that his first method is not quite so convenient or so rapid as the bromoil method practised in this country. His remarks on the degree of inking possible seem to suggest troubles that we do not meet with very often. As a rule there is no difficulty in obtaining contrast, even without the aid of "muslin, rubber, or eraser," if a good bromide print existed in the first instance, and M. Dillaye's suggestion that the possibilities of inking are strictly limited seems to show that his method is not as effective as it might be. He seems to depend solely on the bichromate bath as a hardening agent. That is to say, his print is treated in very much the same way as a "carbograph" print. The bleacher he favours is not a hardening bath, and it is very doubtful if the plain bichromate bath is nearly as powerful as the combined hardening and bleaching bath that we ordinarily use. It is quite possible that the use of a plain bichromate bath before the application of the regular bromoil bleacher might add to the toughness of the image. It does affect the image in some way, as I pointed out a short time ago in reference to sulphide toning, and it is therefore worth trial in the bromoil process. It is a little difficult to follow M. Dillaye's theoretical arguments in support of the view that the hardening bath should be used before fixing. I have found no difficulty in getting a fixed and finished enlargement into perfect condition, and it certainly seems to me that this is a far more convenient method of working.

The second method given by M. Dillaye is for all intents and purposes the ozobrome method. This more or less failed with the old ozobrome manner of working, as it was found very difficult to preserve the details in the high-lights. It was impossible to rely on success, but the new method of ozobrome as now advocated by Mr. Manly seems to have got over this trouble. M. Dillaye's success with the transfer method

probably depends on the nitric acid bath which he commences with, and advocates for the purpose of hypo elimination. far as I can see this simply takes the place of Mr. Manly's bath, and possibly M. Dillaye has mistaken the effects to want of acid to the formation of a silver solvent of the nature of Farmer's reducer. The hypo present in the worst case may be very minute in quantity, and the bichromate must be disposed of it before it has any chance to act as a solvent, therefore it does not appear as if the eliminating action of the acid can be of any consequence.

M. Dillaye seems to think that the transfer method is preferable to the direct one because a number of prints can be made from one bromide print. But this bromide enlargement has to be specially made, as it must be reversed, and if one has to make one bromide enlargement, one may just as well make half a dozen. They will take very little more time, and the finished preparation of half a dozen bromoids from one will be a much quicker operation than the making of half a dozen successive transfers from one print.

It is noticeable that in neither of M. Dillaye's methods does he hint at the use of acid for assisting in the preparation of the image. He actually uses it in both cases, but in the case he refers to it as a hypo eliminator, while in the other he simply states that the bleacher containing the acid is preferable, and that he employs it exclusively. It would appear that he has omitted to note the importance of acid in both bromoil and the ozobrome processes. Possibly it has occurred to him that it may assist in the hardening process in some obscure fashion, and the fact that it does do so perhaps be as much of a surprise to him as it was to me when working out the bromoil process. Even in the carbograph process acid is used. It is applied for the purpose of destroying the developer, but how far it affects subsequent hardening is a matter of doubt.

C. WELBORNE PIPER

## THE PHOTOGRAPHY OF COLOURED OBJECTS IN PRINCIPLE AND PRACTICE.

[The following article, which will be completed in a succeeding issue, is composed of several chapters from a book by Dr. O. K. Mees, to be issued under the title of "The Photography of Colour." Dr. Mees' treatise so well explains matters in practice of orthochromatic photography that frequently present difficulties, that by permission of his firm we quote from advance sheets of the book. The full text of the latter we would recommend to the perusal of our readers, for the sake of the chapters on portraiture, landscape, reproduction work, and coloured objects. Messrs. Wratten and Wainwright will shortly publish the volume at a nominal figure.—Eds. "B.J."]

### On Orthochromatic Screens.

The facts which we have considered will point to some of the conditions which an orthochromatic screen—i.e., one which is to produce a greater approximation to the distribution of sensitiveness of the eye than is possessed by the plate—must fulfil. In the first place, the function of an orthochromatic screen is to absorb the blue, and it must not absorb the green, or, if panchromatic plates are used, the red. This disposes at once of two types of screens which are still to some extent in use.

*The Brownish Glass Screen.*—This screen absorbs some of the blue, but it also absorbs a great deal of the necessary green, and

even some of the red, so that it is of small practical use and requires quite unnecessary increases of exposure.

*The Green Screen.*—This screen has been recommended on the ground that practical trial proved it to give exceedingly good rendering. The actual fact is that a green differs from a yellow in the absorption of the red; consequently, if it is used with a plate which is not sensitive to red, the effect of a green screen is identical with the effect of a yellow screen, while if used with a plate that is sensitive to red the green screen does to some extent the advantage obtained by using a red-sensitive plate. Since also these green screens usually have a consid-

ption in the green itself, they increase exposure to an unnecessary extent, and are therefore inadvisable.

r screen, then, must be yellow, but it is possible for a n to be yellow without having the correct absorption. The n which absorbs the violet-light will be yellow, but it may mit the ultra-violet, and in this way a screen of apparently depth may be less satisfactory than a lighter screen having re complete absorption of the ultra-violet.

orthochromatic screen should as far as possible entirely b the ultra-violet, but it should not completely b any of the visible violet or blue. It may absorb the le violet and blue to so great an extent that the photo- tic effect of the particular plate which is being considered be equal to the visual effect of those colours. If it absorbs too completely a deep violet will appear as black, which ly is not what is intended, and a screen should therefore e too sharp-cut in its absorption.

ffection on the statements already made in this article show that the idea of adjusting a light screen to a particular is not really a feasible one at all. It is often stated that ular screens are adjusted to particular plates, but except for very strong, fully correcting screens which are occasionally this is not a fact, and a screen which is satisfactory for commercial orthochromatic plate will be equally satisfactory ny other, assuming that no attempt is made to *completely* et either. Since a screen which completely corrects the ary orthochromatic plate involves at least twenty times the al exposure, it is clear that the light screens of commerce ot be said to be adjusted to the plate in any real sense. actual curves produced by imposing the Wratten Panchro- e plate behind the three K screens are shown in the next tration (Fig. 13).

Fig. 13.—Wratten K Screens on the Panchromatic Plate.

will be seen that with the light K 1 screen about half of whole effect of the plate is in the blue, about 1/3 being in green and 1/6 in the red. With the K 2 screen the red and are nearly equally divided, while the blue only has about of the effect of the others. With the K 3 the curve approxi- s with the luminosity curve as seen by the eye. Fig. 14

shows the effect of these same three screens upon the "Allo- chrome" plate. The much smaller effect of the screens upon this plate than upon the panchromatic is worthy of note.

### The Rendering of Colour Contrasts.

By orthochromatic photography we intend to imply the use of a fully colour-sensitive plate, such as the Wratten Panchromatic, combined with a filter of necessary strength, to give approximately the same tone rendering as that seen by the eye. It must be remembered, in the first place, that to the eye objects are picked out from their surroundings by contrast, and this contrast may be of two kinds—it may be tone contrast or it may be colour contrast. In the case of tone contrast, if we imagine ourselves to be dealing with a monochromatic scene, the panchromatic plate will render tone contrast within a considerable range as seen by the eye, but in the case of colour contrast the question will require more careful thought. Suppose that we have two objects, the one superposed upon the other, and separated from each other purely by their colour contrast—e.g., a red field containing a patch of green—the contrast between them is marked to the eye, although

Fig. 14.—Wratten K Screens on Allochrome Plate.

the tone contrast is very nearly nothing—that is to say, the two appear of much the same visual luminosity. If we photograph them upon an ordinary plate both are black to it, and we get our contrast represented by one uniform field of black; the colour contrast has disappeared, and we shall have a totally unsatisfactory rendering of that which we are photographing. If, however, we photograph it upon a green-sensitive plate, then the green will be picked out from the red as brighter, and we shall get a certain degree of contrast of a kind, but if we photograph it upon a panchromatic plate with a K3 screen so that we get a rendering of both colours in their true luminosity value to the eye, the contrast disappears and the colours are represented by a uniform field of grey.

What, then, must we do to obtain a satisfactory rendering

of this colour contrast? Clearly it is not possible to render colour contrast accurately in monochrome so long as we retain the rendering of correct luminosity values for our colours, and consequently we must sacrifice the correct rendering of either the red or the green. If we use a lighter filter or a green filter, the green will appear the brighter and the red the darker; if we use a deep orange filter the red will be brighter, the green darker; and which we shall do must be governed by circumstances. As a general rule, if we must correct wrongly for the rendering of colour contrast it is usually better to over-correct towards the red, since red is a strong colour, while green is a weak. For example, in a field of yellow corn of a deep yellow colour we may have poppies standing out which are nearly as bright as the corn, and it is necessary to decide whether we shall render them as brighter than the corn, or as darker. Probably on an actual measurement of luminosities they would be a little darker than the corn, but remembering the way in which the strong red attracts the eye, it would seem that a more faithful rendering would be given by over-correcting and rendering the poppies as brighter than the corn. Again, the top of a yellow haystack against a deep blue sky may give a result, with perfect orthochromatism, where the haystack is indiscernible from the background. Here, again, I personally should be inclined to over-correct, though the individual worker must decide for himself. A thing to guard against always is the danger of basing one's consideration of monotone rendering upon photographs; few people have been trained in engraving, and photographers are apt to take their conception as to the tone value of bright green grass, for instance, from photographs, which invariably show it as dark, if not black. Frequently in a spring landscape the hedges and grass are almost the brightest things in the whole landscape, and they should clearly be rendered as light greys, but so uniform is the belief among photographers that grass is black, that a rendering as light grey will almost always provoke the comment that the picture was over-corrected.

The most important case of colour contrast occurs in the copying of pictures, and for this purpose I some time ago advised a special method, which it is desirable to explain here.

This method depends upon the use of tricolour filters, the plate being exposed first through one filter and then through another, in order to get the desired colour rendering result. It is first necessary to remove a common misconception which one frequently finds repeated in text-books and the technical press, namely, that the effect of printing from the three tricolour negatives on one piece of paper would be to give an orthochromatic result. This would give an isochromatic result—that is to say, one in which all colours are rendered of equal strength independently of their visual brightness. This results in an excess of brightness in the red and blue, especially in the blue, and insufficient brightness in the green, the whole colour rendering taken this way being wrong. Suppose that we put a set of filters in front of our lens fitted in a slide-past holder, so that we can expose the plate through the three filters in succession without removing camera or lens. Then we may give an exposure through the three filters in proportion to their ratio upon that plate. Supposing, for example, that we have a plate and a set of filters such that the blue requires six times the normal exposure, the green requires twelve times

the normal exposure, and the red requires eighteen times unscreened exposure; if we give through the blue twice normal exposure the plate will be one-third exposed. Now through the green four times the normal exposure; the plate is now two-thirds exposed. And now superpose on this exposure through the red screen of six times the normal exposure. We have now a negative combining our three colour negatives in one, but it will not be correct rendering at all will give all blues much too light, and greens too dark, and results will be unsatisfactory. With the "Wratten" filters plate, owing to the fact that the green transmits a certain amount of blue, correct colour rendering is obtained by giving two-thirds of the exposure through the green and one-third through the red. Thus, in the example just given, where ratio of exposures for the three filters was 6, 12, 18, the correct rendering would be given, together with correct exposure, giving about eight times the normal exposure through the green, and four times through the red. Since this proportion of the mixed exposures of green and red gives a correct orthochromatic result, we can exaggerate red or green by increasing the exposure of one filter and diminishing the exposure of the other. For instance, if we give 8 secs. exposure through red, and 6 secs. through the green, we shall have exaggerated red at the expense of green; on the other hand, if we give 10 secs. through the green and 2 secs. through the red, we shall exaggerate greens at the expense of reds. If we wish to diminish greens altogether and bring up reds and blues we can use our red filter and blue filter, and so obtain the rendering that we desire by altering the relative exposures through the three tricolour filters.

This method may sound rather far-fetched, but as a matter of fact it has been adopted by some very skilled picture copyists, and in each case where it has been adopted they have, I believe, been perfectly satisfied, and have never gone back to a multitude of yellow screens. A very important point about this method is, that all the while one is working one knows exactly how far one is from correct rendering, so that instead of more or less over- or under-correcting by a screen of which the action is somewhat uncertain, one can say quite definitely, "I have exaggerated the reds in that reproduction 50 per cent. because it was necessary to pick out the red against the green in the shadows"—a statement which is both more scientific and more useful both to the speaker and hearer than a statement such as "I used a rather dark screen for that in order to get better correction."

A word of warning is necessary here as to the quality of the filters required for this. It will be seen that the three images are literally superposed upon one another, and consequently the very smallest shift in any one of these images will produce a double image in the result, consequently a much higher grade of filter is required than for ordinary reproduction purposes. It is not sufficient that the images should be of the same size, but they must actually fall on the same place on the focussing glass. This can only be accomplished by the use of filters cemented in optical flats of the very highest quality, or else by the use of gelatine film alone. It will be a disappointment if I emphasise the fact that what are usually known as "first-class cemented filters" will not do for this purpose.

C. E. KENNETH MEES, D.Sc., F.C.S.  
(To be continued.)

Mr. W. F. MEADOWS, for thirteen years past with Messrs. Newman and Guardia, has now joined the staff of Messrs. Adams and Co., of 24, Charing Cross Road, W.C.

HERR DÜHRKOPF'S FESTMAHL.—The celebration of twenty-five years of portrait photography, which Herr Dührkoop kept with many friends at his studios in Hamburg on October 1, was marked by appreciation of his work in England. This took the shape of a

small bronze statuette, by Morris Harding, presented to Dührkoop by the following friends of his in London:—A. H. P. George E. Brown, E. O. Hoppé, F. J. Mortimer, W. H. Smith, Tilney, and H. Snowden Ward. The statuette, which is a reproduction of one exhibited at the last Royal Academy, was presented on behalf of the above donors by Herr Wolf-Czapek, editor of "Photographische Industrie."

## A SIMPLE LENS-CALCULATOR.

An easily made appliance, available for automatically solving numerous questions in photographic optics, particularly those problems of a practical kind that occur almost every day in the average photographer's work, may not prove unacceptable to those who do not care to be perpetually consulting tables or recalling algebraical formulæ. It can be used, among many other purposes, for finding what focus supplementary lens is required to alter the focal length of an existing lens to a given extent; estimating the focal length of combined lenses; ascertaining the principal focus of a lens; calculating the conjugate foci for any given size of enlargement or reduction with a given lens; or for obtaining the ratio between the size of image and that of the object with any extension and distance of the camera. It consists of two parts: a rectangular scale divided into 10th in. squares, and a combined ruler and protractor. These may be made from moderately thick Bristol board. To prepare the scale (Fig. 1) draw carefully a true rectangle, which may

Fig. 1.

conveniently measure 6 in. by 5 in. Divide this all round into tenths of an inch, and join the lines to form squares. Then number every fifth division on the bottom horizontal line and the right-hand vertical line, starting from the right hand bottom corner in each case. From the same corner draw a diagonal line at an angle of 45 degrees.

To prepare the ruler and protractor (Fig. 2) set out the straight

Fig. 2.

portion about 10½ in. long and mark the centre O. From O as centre, describe a semicircle of about 4 in. radius, and an inner one of about 3 in. radius, the exact radii being immaterial.

Then cut out very carefully round the outer lines and remove the space in the centre. To mark the scale of ratios on the upper semicircle, proceed as follows: Place the centre O of the protractor on the diagonal line of the rectangle, and adjust the lower edge of the ruler so that it cuts the horizontal scale and the vertical scale at identical figures—for example, 10 and 10, or 20 and 20. Mark with pencil where the semicircle cuts the diagonal line and number it 1. To obtain the ratio 2, still keeping the centre of the protractor on the diagonal line, place the ruler so that its edge cuts any figures on the horizontal and vertical scales which are in the proportion of 2 to 1, as, for example, 16 and 8. Mark where the semicircle cuts the diagonal as before. Obtain the other ratios up to 8 in the same manner, in each case first placing the centre of the protractor on the diagonal, and then setting the ruler on figures that stand to each other in the same proportion as the required ratio. The divisions may now be ruled from the edge of the semicircle towards the centre and neatly inked in, as shown.

In its simplest form, the lens calculator is now completed. It may be further elaborated, as will shortly be described, but it will perhaps be better first to explain the method of making and using it which involves the fewest complications. A selection of problems and the manner of solving them will be given, sufficient for most of the purposes the ordinary worker is likely to require, although it must not be thought that the possibilities of the appliance are thereby exhausted.

### Problem 1.

It is required temporarily to convert a 30 in. focus lens into one of 18 in. focus. What focus supplementary lens will be required?

Fig. 3 illustrates the solution of this problem. Place the edge

Fig. 3.

of the ruler against the focus of existing lens on the horizontal scale. Set the centre of the protractor at the point on the diagonal where the two lines from 18 meet. The other end of the ruler will then indicate the required focus of the supplementary lens on the vertical scale—i.e., 45 in.

**Problem II.**

A lens of 24 in. focus is to be placed in contact with another of 12 in. focus. What will be the focal length of the combination?

Place the ruler on 24 and 12, on the horizontal and vertical scales respectively, the centre of the protractor being on the diagonal. The lines touching the centre of the protractor will indicate the focus of the combination—i.e., 8 in.

**Problem III.**

The image on the focussing screen is one-quarter the size of the object, and the distance from the object to the lens centre (major conjugate) is 30 in. What is the focus of the lens?

Place the centre of the protractor on the diagonal, and set the ratio 4 on the semicircle also on the diagonal. Move the protractor along the diagonal line, still keeping the centre and ratio on this, as before, until the ruler touches 30 on the horizontal scale. From where the centre of the protractor cuts the diagonal may now be read the focus of the lens—i.e., 6 in.

**Problem IV.**

With a 10 in. focus lens, it is desired to enlarge from half-plate to whole-plate. What must be the distances between easel and lens and negative and lens?

Set the centre of the protractor on the diagonal at the point where the lines from 10 on both the horizontal and vertical scales meet. Set the ratio 2 of the protractor also on the diagonal. The ruler will then indicate the two distances required where it cuts the horizontal and vertical scales—i.e., 30 in. and 15 in.

The following table shows at a glance the procedure for the above and similar problems. If the ruler and the centre of the protractor, or the two ends of the ruler, are placed on any two of the factors as directed by the upper line, the third factor in a line with these will be indicated automatically. Where there are two factors in any column, numbered 1 and 2, first place the ruler or protractor on No. 1, and then, keeping it parallel,

set it on any one of the factors numbered 2, in the line below. The other two factors in that line will then be indicated. In every case, the centre of the protractor must first be set on the diagonal line.

Horizontal scale.	Diagonal line.	Vertical scale.
Focus original lens.....	Required focus .....	Focus supplementary lens
Focus of first lens.....	Combined f. cua.....	Focus of second lens
Major conjugate (distance object to lens centre)	Focus of lens .....	Minor conjugate (distance image to centre lens)
No. 2. Major conjugate .....	No. 1. Ratio of enlarge- ment or reduction.	No. 2. Minor conjugate
No. 1. Size of object .....	No. 2. Focus of lens ....	No. 1. Size of image
No. 2. Major conjugate.....	No. 2. Focus of lens .....	No. 2. Minor conjugate

The simplest form in which the lens calculator may be made having been described, various improvements, which any one with a little mechanical skill may introduce, will now be suggested. A slot may be cut along the diagonal and the protractor pivoted at the centre to move freely along the slot. This saves a good deal of adjustment, and by turning the protractor on its pivot conjugate foci for any lens and any ratio are instantly obtained. If this is done, the rectangular scale should be mounted on a wooden block, while the protractor may advantageously be of metal or celluloid.

Another improvement is to introduce a scale of degree on the lower semicircle of the protractor, graduated to show the angles made by the ruler with the horizontal scale, and to graduate the ruler itself in tenths of an inch, starting each way right and left from the centre of the protractor. This is a refinement that perhaps will have no immediate use to the ordinary worker, but would enable the optician or geometrician to make many interesting experiments. To graduate the protractor to show the angles the ruler makes with the horizontal scale, divide it as usual into 180 degrees; but, instead of numbering these in the ordinary manner, mark 45 degrees as 0, 50 degrees as 5, and so on. If this is done correctly, 90 degrees should come on what would otherwise be 135 degrees.

A. LOCKETT.

## THE "MIRROR" ART EDITOR ON PRESS PHOTOGRAPHY.

MR. HANNEN SWAFFER, art editor of the "Daily Mirror," opened the Thursday lectures at the London County School of Photo-Engraving, at Bolt Court, off Fleet Street, London, on October 1. "One of the very best, the most serviceable, of all the talks we have had," was the comment of a quite enthusiastic auditor at the close, and the gathering endorsed the acknowledgment. We have not space for a long and detailed report. Besides, Mr. Swaffer answered questions in the intimacy of this small lecture room with a freedom and a preciseness which arose from his knowledge that the answers were not for general publication. Herein consists a great part of the value of such gatherings, that there is often the freest information on points as to which ordinary business men are very reserved—information which those who do not take the trouble to attend these free lectures will vainly hope to find presented to them in some report. Scrupulously respecting the lecturer's wish in regard to his more private intimations, there is yet a good deal to report. We gather that not only do at least nine London dailies regularly use illustrations, but in the provinces "The Manchester Guardian," "The Manchester Daily Despatch," "The Manchester Courier," and "The Leeds Mercury" are among notable users of illustration plates produced through the photographer's art. One great daily of the provinces has just engaged a news photographer of its own. Twelve London weeklies give whole pages to pictures. There is an ever increasing demand for clever young fellows who know how to take a news photograph; and if they bring a good subject around to the "Mirror" office, they will have it fairly examined (this, by way of answer to one in the audience who said Editors would

not trouble even to look at some things which were offered). The editor of a daily paper cannot, by Mr. Swaffer's testimony, reckon on more than about forty photographers in England who can be considered fully competent and reliable for his purpose. A railway disaster occurs in an important town; there are, say, four professional studios and forty or fifty amateurs in that town, but not one of the whole company can grasp the fact that there is newspaper market for views of the disaster. The editor must race his men off in a special train for any remainders of good views. A newspaper photographer always earns four or five pounds a week if he knows his way about; and there is no photographer of any sort—running a studio, or a chemist's shop, or what not—who could not earn useful occasional sums through newspapers. There is no first-class Press photographer (according to Mr. Swaffer) at the moment in Birmingham, or Liverpool, or Newcastle-on-Tyne, or Edinburgh, or Plymouth, or Folkestone, or in scores of other places. Birmingham should yield a good man, adventuring there, £5 or £6 a week straight off. "Photograph people in motion—doing something," Mr. Swaffer advises; avoid stiffness. Do not take a big group unless it is historic; unless you are at Windsor and have such an opportunity as Messrs. Downey lately had of taking a group of the King and Kaiser, and the King of Spain, and ever so many heirs to thrones and other royalties. It seems to be the irritating experience of some editors that camera men even when they do send a group of some interest are apt merely to string off the names without any distinguishing numerals whereby the editor is to identify this or that great man—or greater woman. When stalking a prominent man track

down in all legitimate ways, till you have him playing a part in some scene of human interest. Lord Milner is taken at hospital simply standing, in company with a doctor and a nurse. Lord Milner the same day goes on all fours and gives a little rent a back ride in one of the wards; and a snap of that kind would have had real value. The hospitals wanted publicity and there probably would have been no extraordinary Cerberus for the insistent camera man to get past.

Halfour at the golfing ground would have been followed by a man with the press photographer's instinct and—who knows?—might have been snapped just after the golf-ball struck him. We might, at least, to be as alert as that golf-ball. Another urging Mr. Swaffer's: let the press photographer make sure of his facts. Indeed, get all the facts you can. Let the editor strike what he deems unimportant. The paper will pay well for what it does use. Let them be sure, especially names. Use a good quick working lens. The photographers of the "Mirror" the Goerz-Anschutz camera is a very good one for the purpose. Develop the negative to get strong contrasts of black and white. Blue-tint tints are no good in press photography, unless the paper is superior to that ordinarily used for news or the printing is very good. Some waste time and money in costly silver prints; they are not only unnecessary, but frequently not nearly so good as many bromide prints. Buy a good enlarging lantern so that you need not be wasted in waiting for negatives to dry. Mr. Swaffer thinks the amateur may find it well in many cases to work with a photographic agent; there are eight or nine good agents in London, he says. Send by train when you can—for the wireless telegraphic transmission of photographs by the method of

Korn or Knudsen, is not yet available for young Mr. Snapper down at Takenham. If you have something good, send by train and see that it really does get on the train, especially if it is something which you are sending from abroad. Wire time the train arrives and be precise as to station. Be precise all the time. Mr. Swaffer is pathetically awaiting now at the "Mirror" office some fine photographs obtained under all sorts of difficulties by good men sent over to the Continent for the purpose. After a year or two's waiting for the train he becomes less hopeful and in any case the first freshness of the subject tends to wear off. By the way, Mr. Swaffer had much of great interest to say as to his visit to Madrid in charge of photographers at the time of King Alfonso's wedding. On the point of time—a photograph of a boxing-match between Tommy Burns and Gunner Moir was at hand at twenty to twelve (midnight). In exactly an hour and a half—at ten past one—the machines were turning out at 80,000 an hour copies of "Mirrors" containing plates of this match. In the interval the plate was developed, the print made, sized up, touched up, engraved, locked in the forme and stereod about twenty times. Ten shillings and sixpence seems to be the ordinary payment by a paper using a photograph. But fancy prices—large sums—are paid at times for sole rights of pictures of rare interest. There are compensations in addition to the money gain; and Mr. Swaffer tells great tales of the adventurous life and almost unlimited travelling from one interesting region to another which is the happy fortune of the press camera man who has a good reputation. As to the extent of the art, in the "Mirror" office alone about 500 pictures a day are examined as a rule, and about forty are used.

## THE BRITISH JOURNAL ALMANAC—PAST AND PRESENT.

With only one week before the closing of the forthcoming "British Journal Almanac" for the press, it appears peculiarly opportune to cast a glance backwards upon the first issue of the "Almanac," forty-seven years ago. The following is sent by an interested correspondent, who recently spent an hour or two inspecting this 1861 "Almanac."—Eds. "B.J."]

"thy shadow never grow less!" The good Oriental regards any action in bulk as an indication of misfortune, but we more numerous Westerners are apt to think otherwise, and are therefore grateful for the reduction in size of the "British Journal Almanac." How many of my readers, I wonder, are familiar with the first issue—that of 1861? The pages, of which there are six of editorial matter and forty-two of advertising, measure 4 x 2½, so that with its thin paper covers it might well fulfil the purpose mentioned in the "prefatory notice," which reads as follows:—

Within the limited time and space placed at my disposal I have endeavoured to throw together such matter as I conceive may be of utility to the photographer when travelling, or otherways out of reach of the ordinary works of reference.

The Calendar will remind the reader of the days, whilst in other part he will find the places and hours of meeting of the various British Photographic Societies, together with a list of their officers.

To Mr. George Shadbolt I have to render my thanks for furnishing me with the formulæ and summary of the best ascertained method of manipulating the Collodio-albumen, Taupenot, and other therm processes.

The size adopted is such as to allow of our Almanac being placed in any photographer's pocket-book, whilst by interleaving the almanac it may be employed as a diary.

No separate features in the present "Almanac," the "Epitome of Progress," and the "Recent Novelities," are embodied in one article, Retrospect of our Photographic Year." The prologue, as it opens quietly enough:—

As an ancient patriarch in solemn moments looks back upon his generation, thinking of those within his ken who have sprung into vigorous existence, progressed steadily on their life's way, and are about to close their eyes, whilst others have sunk upon the road, after a short-lived, feverish existence, but of great promise, so do we, as we prepare to toll the passing-bell for another year, in contempla-

tive mood love to scan the pages of our Journal, to see what progress we can record, what processes hold their own, and what have been superseded in the struggle for life.

But, apparently not content with merely witnessing and noting the struggle, a very vigorous kick is soon given to accelerate the departure of some of the processes. "Sources of light" are under discussion:—

Photographers have been asked, by a recently formed company, to adopt the limelight, as very suitable for their purposes, when the sun is sulking and skulking; but as their patent only involves an improved form of lime holder and burner, the characteristics of the light being the same, from past experiments we see no reason to believe that it is in any way suited for such purposes, being remarkably deficient in actinic rays. Again, Professor Way's light. . . . the cost and trouble entailed in the production of this source of light is very considerable . . . therefore Moule's light seems to be, as yet, the only practical means of obtaining artificial light for photographic purposes.

From all of which it will be seen that the correspondence as to the varying merits of different illuminants, appearing not long ago in the "B.J.," is but another instance of repetition in history.

Under the heading "Lenses," we are referred to "a description of a lens of peculiar construction, invented by Mr. Sutton, under the name of the 'Panoramic Lens,'" which is damned with the faint praise that

it is not likely to come into general use, though it might be of service for military and naval purposes. . . . Mr. Dallmeyer has introduced a "new triplet achromatic lens," which, in the hands of Mr. Downes, has afforded the most satisfactory results. . . . Mr. Heath's view at Tavistock, covering a plate 12 by 10 in., well to the edge, was taken by a lens of only 10½ in. focus, being put forth by Mr. Ross as yielding pictures 8½ x 6½, whilst the landscape taken extended over a depth of two miles, yet all is well in focus.

Thus were the great reputations of these two names built up.

In "Chemicals and Apparatus" we are told that—

The experiment of Mr. John Williams deserves the attention of all honest-minded manufacturers, and the consideration of photographers generally, as showing how many of the evils that afflict a collodionised plate may be traced to nitrate of silver, prepared without sufficient care, but which they may have purchased as the purest article obtainable, namely, the recrystallised nitrate of silver.

The professional of to-day often refers regretfully to the "good old days," when competition was not so keen, forgetting that in those times the technical side of the business was frequently a source of worry that is almost impossible to realise by the worker accustomed only to the apparatus and materials now supplied.

"Collodion Processes" and "Printing Processes" each receive a paragraph, as does also our old friend, which, like the poor, is always with us—"The Nature of the Photographic Image." An interesting paragraph on the "Applications of Photography" winds up with a description of the process of Paul Pretsch, together with the statement that—

As the illustrations referred to were worked at the steam platen and cylinder machines, it will be seen that we have put this process to a severe test, and that, considering it is quite in its infancy, the results are very promising for the future of cheap illustrated educational literature.

It was not foreseen that printed matter other than educational literature would be thus illustrated, and that generations yet to come would find their chief mental pabulum in publications of the halfpenny weekly "Comic Bits" type, in such quantities as to amass for their producers princely fortunes.

The advertising pages also are interesting. The "B.J." itself has one, and except that it was then "Edited by George Shadbolt, and published on the 1st and 15th of each month, price 4d., by Henry Greenwood, 32, Castle Street, Liverpool," the descriptive matter would apply almost verbatim to the "B.J." as we know it now. Among the opticians we find "T. Ross, 2 and 3, Featherstone Buildings, Holborn," while "J. H. Dallmeyer (son-in-law and pupil of the late A. Ross)" makes his announcement from 19, Bloomsbury Street. In but one instance do I see an address which I recognise as being

that at which a business is still being carried on, and that is interesting quarter-page of the London Stereoscopic Co.—

"CARTES DE VISITE,"

20 for 20s.

Photographed by an Eminent Foreign Artist in a most superior style.

LONDON STEREOSCOPIC COMPANY,

54, CHEAPSIDE, LONDON.

Detention 3 minutes. Albums from 12s. 6d. each.

The trade workers of to-day, if they do not figure in the "Almanac," seem to have had no less modest personages to claim their abilities for them. One individual, Mr. Bassano, Regent Street, London, takes a full page on which to say—

Being the only artist who has made the finishing photograph black and white (or sepia) his sole and especial study . . . having organised a staff of artists to assist him . . . he is prepared to retouch photographs in the highest style of finish, with utmost despatch, and at moderate charges. The rapidity and success with which Mr. Bassano works may be imagined from the fact that during the past three years he has finished (highly) upwards of 3,000 portraits, etc., etc.

But this average of but a thousand portraits a year fades into insignificance before that of one J. Alexander, of Halifax—

12,000 portraits, highly finished, in oils and water-colours, J. Alexander and his staff of artists during the past seven years. Portraits beautifully finished in oil or water as follow:— $\frac{1}{2}$ , 5s. 6d.; 4s. 6d.; 5 by 4, 6s.;  $\frac{1}{2}$ , 6s. 6d.; 1-1, 7s. 6d.; 12 by 10, 12s. Satisfaction guaranteed.

Printing is represented in the person of Thos. J. Barnes, of Market End Road—

Printing executed with the utmost care, and at the lowest price consistent with the production of good prints, and the permanency the present state of the art will admit of. Permanency washing guaranteed.

The writers of the trade-workers' advertisements appearing were in the "B.J." at present must verily look to their laurels!

## THE USE OF ORGANIC SULPHUR COMPOUNDS AS SUBSTITUTES FOR HYPO IN COMBINED TONING AND FIXING BATHS.

THE instability of hypo in presence of the smallest quantities of acid and the necessity of completely washing out all hypo in order to ensure the permanence of the print has led us to make experiments with a view to removing these drawbacks attached to the combined bath. In order to find a substitute for hypo for this purpose we had to discover some substance which:

(1) Should easily dissolve silver chloride without affecting the gelatine.

(2) Should reduce the per salt of gold to the state of proto salt—e.g., auric chloride to aurous chloride.

(3) Should combine with haloid salts of silver, as also with soluble silver salts, in such a way as to render these latter removable by washing of water and to keep them undecomposed by a large excess of water. None of the mineral substances possessing solvent properties for chloride of silver, such as ammonia, potassium cyanide, ammonium sulphocyanide, correspond with these requirements, and we therefore endeavoured to find organic compounds which would serve the purpose. The only ones hitherto known to dissolve silver chloride are the thio-ureas and thiosinamine, or allyl thio-urea. Our experiments were therefore directed to these classes of compounds, and we endeavoured to prepare various substitution products of thio-urea,\* such as monoethyl and diethylthio-urea, monophenyl, and diphenylthio-urea, phenylmonoamido, and phenyldiamidothio-urea, monoamido, and diamidothio-urea.

We found that none of these substances, except thiosinamine and

thio-urea, dissolved sufficient quantities of the haloid silver salts to allow of their use in fixing or in combined toning and fixing. We therefore had to confine our attention to these two substances, which one (thiosinamine) has been pointed out by Liesegang as capable of replacing hypo in the combined baths.

Thio-urea, like its isomer, ammonium sulphocyanide (from which it is prepared), dissolves silver chloride, forming a double combination of silver chloride and thio-urea. On evaporation of the saturated solution of the silver chloride in the thio-urea, the compound can be isolated in the form of white shining needles, having the composition of 13 molecules of silver chloride to one of thio-urea and corresponding 95.4 per cent. of silver chloride, whilst the saturated solution of silver chloride in thio-urea contains only 29.8 gms. of silver chloride for each 100 gms. of thio-urea, representing a formula of one molecule of the chloride to 13 of the urea, a compound which has been separately prepared. These compounds are very stable in aqueous solution, and do not produce, as does the double hypsulphite of silver and sodium, silver sulphide, on heating of aqueous solution. Further, they are not decomposed by excess of water as are those containing ammonium sulphocyanide.

Thio-urea reduces chloride of gold as readily as does hypo. One of the drawbacks that it presents is that it cannot be used in a strong solution than 6 per cent. without affecting the gelatine, even in the presence of alum. Moreover, the solution of the haloid silver salt in thio-urea easily decomposes in the presence of alkali forming silver sulphide. In consequence of the comparative weakness of the combined bath in thio-urea the toning should be longer than with hypo, since the solubility of silver chloride is only 1.49 gm. per 100

\* We prepared the substituted thio-urea by the action of aqueous ammonia on the amines and semioles, these bodies being obtained by the action of carbon disulphide on the amines or hydrazines followed by heating with mercuric oxide.

of 5 per cent. thio-urea solution, whilst it is 1.99 gm. in the same volume of 5 per cent. hypo. Thus the toning action should be sufficiently slow in order that fixing may be complete at the same time. Using thio-urea in a 6 per cent. solution, together with a small quantity of alum, the conditions above mentioned are complied with. Not only is the silver salt dissolved without alteration of the gelatine, but the gold is instantly reduced from the auric to the aurous state, and no bodies entering into the composition of the combined baths are precipitated.

There is an essential difference between the action of the thio-urea and that of hypo in a combined bath. An ordinary solution of this kind made with hypo has practically a toning action only when it contains a small quantity of lead salt. In the absence of lead the toning is extremely slow and the tones are reddish. We have already given the theory which we think explains this fact.\*

In the case of thio-urea not only is the lead salt unnecessary for the toning but it is an actual drawback, owing to its alteration of the half-tones of the picture. We have made experiments to find if other metallic compounds when used in thio-urea toning can play the same part as the lead salt in combined baths made with hypo. The bodies which we have examined, excepting only stannous chloride and zinc nitrate, have not shown any positive action. The best results have been obtained simply by using thio-urea, alum, and gold chloride in such proportions that the thio-urea exerts no action on the gelatine and the toning is not so rapid that it is completed before the print is fixed. The following bath has been found to fulfil these conditions:

Thio-urea .....	60 gms.
Alum .....	30 gms.
Gold chloride, 1 per cent. solution .....	60 ccs.
Water .....	1000 ccs.

The time of toning is about six minutes, and the tones obtained are very similar to those produced in the ordinary combined bath. The prints thus toned cannot be washed in ordinary water, owing to the fact that the alkalinity of the latter is sufficient to produce during the washing process a decomposition of the double salt of silver and thio-urea, giving rise to black stains. This can be avoided by washing in distilled water or using ordinary water containing 1 gm. of acetic acid per litre; a larger quantity of acetic acid is liable to affect the gelatine. The washing is complete in six or seven treatments, each of two or three minutes, with the weak acid solution, employing altogether 1 litre for ten 7 by 5 prints.

Thiosinamine has a greater solvent action on silver chloride, but not as great as hypo; 100 gms. 1 per cent. hypo solution dissolve 4 gms. silver chloride, whereas 100 ccs. 10 per cent. thiosinamine solution dissolve only 3.17 gms. silver chloride. Thiosinamine, like thio-urea, instantly decolourises gold chloride solution, and can be used for the preparation of combined baths. Owing to its small solubility it cannot be employed of greater strength than 6 per cent. Water will take up 10 per cent., but a solution of this strength after a time deposits transparent crystals, which appear to be a hydrate of thiosinamine. Like thio-urea, the best tone is obtained without the addition to the bath of any other substance than chloride of gold and alum, the latter in quantity to give a solution of weak acidity. If the solution is too acid the gelatine is affected, and we have been led from these considerations to the following formula:—

Thiosinamine .....	6 gms.
Alum .....	2 gms.
Gold chloride, 1 per cent. solution .....	6 ccs.
Water .....	100 ccs.

Thiosinamine has the same drawback as thio-urea of giving with haloid salts of silver compounds which are readily decomposed by alkalis forming silver sulphide. This fact prevents the use of ordinary tap water for the washing of prints toned with thiosinamine, and the washing needs to be done as indicated above. The result of the above experiments therefore seems to prove that the substitutes for hypo have very little advantage over that substance. Although the silver compounds of hypo are very unstable in the presence of acids, those of the organic substances are likewise in presence of alkalis, and, moreover, have the disadvantages of small solubility and comparatively high price.

## AMERICAN VIEWS OF TWO BUSINESS TOPICS.

[Among the papers and contributions which appear in the "Annual of the Photographers' Association of America," reviewed on another page, are two which we reprint on account of the peculiarly practical subjects on which they touch.—Eds. "B. J."]

### A LESSON IN BOOK-KEEPING.

STOPPING to see a friend of mine, who was doing a very good business in a small studio, we began to discuss the question of business and expense. I found in our discussion that his system of account was not an accurate one. I devised a plan for him which I have since given to a few other friends in photography, who have told me that it was a great help to them, so I thought it a good plan to present it here. The idea is simply this: get a three-column cash book, and on the left-hand side use one column for the cash taken in during the month, on the other or right-hand side place your expenses divided into three parts; use the first column for all general expenses, the second for all your salaries (and, by the way, pay yourself a reasonable salary each week, placing it in this column also), and the third for your stock bills of every kind. At the end of each month add up the columns, which will show at a glance what the different expenses cost you, then carry the salary and general expense totals out underneath the stock totals, and in red place the difference to make the final footing of the right-hand page or expense side balance with the final footing of the left-hand page or cash side. This difference in red ink will show you the cash balance or profit of your studio each month. If you follow this plan closely you will soon discover the losses in your business. It will teach you to notice which expense runs highest.

There are only two ways for your studio to earn more money, either get a better price for your work, and make the figures on the left-hand side of your cash book larger, or the cost of production less, and make the figures on the right-hand side of your cash book smaller, hence the balance or figures in red ink will be larger, thus making your profit larger. If you use this division of expense account and general plan, it will enable you to see where your leaks are and many a dollar will be saved by your studying these interesting figures, for, having made a start in this direction, more divisions will follow, and in a short time a broader plan will present itself, and your eyes will be opened so that you may more readily see the difference in the business that pays from the kind that does not.

G. W. HARRIS.

### SOME THOUGHTS ON ADVERTISING.

It has been said that "The fellow who tries to attract business without advertising is like the fellow who throws his sweetheart a silent kiss in the dark. He knows what he is doing, but nobody else does." Every man in any kind of business at this day and age must admit that advertising pays. The question for each to decide is what way is the best for his own business. Of course, there are extremists among us who insist that photography is a high art or a profession, and self-respecting members should not advertise any more than painters, artists, lawyers, or doctors. One can afford to maintain that position if he has an independent income sufficient to meet expenses until perchance the public discovers that he has something it wants. Most of us, however, are not thus situated, and from the start have to make a living from the business—then it is a business and should be treated as such. For myself, I like to be classed as a business man, and the world in general now accords the good business man as high a place in its esteem as any members of the so-called learned professions. As all successful business men advertise, I see no good reason why I should not and several reasons why I should, so I do, and I think it pays. I refer more particularly to newspaper advertising.

I differ from most advertising experts in their opinion that prices should be quoted, for I never quote prices on photographs in my ads. In the first place, there being no standard of sizes or quality of work, to quote prices means nothing to the average reader; and in the second place my prices are invariably higher than those of my local competitors. The chief object of advertising in our business, as I figure it, is to create a demand, to keep up the public interest in photography so that when anyone speaks of photographs in your locality they will think of your studio first and foremost. It is true that the photographer's best ad. is work of high quality, work that people show with pleasure and pride, but good newspaper ads. supplement and often clinch the impression produced by the

\* Bulletin de la Société Chimique de Paris, 1902.

former. People see a good picture of a friend and pronounce it a fine portrait; they may even be urged to have some taken themselves and say they will "before long," but straightway proceed to forget it. The newspaper ads. don't let them forget, and by the mere force of mental suggestion frequently applied, accomplish their purpose and bring in the customer who finally feels that it is the only thing to do.

Short ads., right to the point, well set up and perhaps illustrated with cuts, but at least located so that they will be read, I find will bring in many an appointment during dull times and increase the number in busy times. Of course, what is good for the person in one locality frequently does not work well for another elsewhere, and methods that succeed in small towns probably would not do in large cities. I am located in a town of only 10,000 inhabitants, but with as many more within easy reach. I have not put out tickets nor made special prices for more than ten years past. I believe that the reason ticket men are able to sell so many tickets is because the great majority of people really want photos, but have not got around to having them made. The main thing is to get them to "do it now." This can be done with more dignity by judicious newspaper ads. than in any other way I know of. I also get out a neat folder at least once a year, which I mail to all probable customers, keep my show windows attractive and quality of work up, but the immediate results of a vigorous campaign of newspaper advertising during the past few months, when business generally has been greatly depressed, have been so gratifying to me that I thought it might be of interest to others.

C. S. BATEHAM.

## Photo-Mechanical Notes.

### Celluloid-Linoleum Electros.

A GERMAN inventor named Michael Sandman, of 60, Elisenstrasse, Dresden, A., has taken out a patent for a method of preparing electros of line or half-tone blocks, in which the matrix used consists of a layer of celluloid and one of linoleum in intimate contact. The specification (No. 13,238, 1908) describes the process as follows:

A sheet of linoleum, of a thickness of from two to four millimetres, made smooth by mechanical means, such as calendaring, is intimately combined with a thin layer of celluloid of similar dimensions and of about from 0.15 to 0.30 millimetres thickness. This is effected by moistening a sheet of celluloid with a heated liquid solution of 30 gms. of camphor to a litre of 95 per cent. spirit and then placing it with its moist surface upon the sheet of linoleum, which has undergone preliminary heating. Both sheets are then subjected to considerable pressure.

According to an alternative method of procedure the combined celluloid and linoleum sheet may be produced by pouring by any suitable means a thin layer of hot liquid celluloid upon the linoleum sheet and then subjecting the sheet first to hydraulic pressure and afterwards to rolling to obtain a smooth surface.

From a composite sheet thus prepared the block or plate is then produced by means of suitable cutting and graving tools, in such manner that the face of the block is formed in the layer of celluloid, and its depth in the soft mass of linoleum. By means of this process defects inseparable from the celluloid process as heretofore carried out are entirely obviated. In the first place it may be observed that from the combination of the layer of celluloid with the foundation of linoleum there is produced in the mass in which the electro is cut a certain elasticity, in consequence of which, when the new process is employed, there is obtained at once a satisfactory covering of ink and a soft toned print, advantages which, in the case of an electro produced by the celluloid process or a printing or half-tone plate of the kind heretofore usual, has only been obtainable by means of overlays, the adjustment of which has required considerable time.

SOUTH LONDON PHOTOGRAPHIC COMPANY, LIMITED.—Capital, £2,000 in £1 shares. Objects: To carry on the business of photographers, photographic enlargers, and reducers, art dealers, dealers in photographic materials and scientific and optical instruments, etc., and to adopt an agreement with F. G. Waghorne. Private company. The number of directors is not to be more than three.

### FORTHCOMING EXHIBITIONS.

- September 11 to October 24.—Photographic Salon. Sec., Reginald Craigie, 5A, Pall Mall East, London, S.W.  
 September 17 to October 24.—Royal Photographic Society. Sec., J. McIntosh, 66, Russell Square, London, W.C.  
 October 13 to 17.—Southampton Camera Club. Hon Sec., S. G. Kimber, Oakdene, Highfield, Southampton.  
 October 14 to 17.—Rotherham Photographic Society. Sec., H. C. Hemmingway, Tooker Road, Rotherham.  
 October 22 to 26.—Hove Camera Club. Entries close October 15. Sec., W. Chater Lea, Cransley Lodge, Dyke Road Avenue, Brighton.  
 October 27 to 31.—Heaton and District Camera Club. Entries close October 12. Secretary, George C. Urwin, 24, Tenth Avenue, Heaton, Newcastle-on-Tyne.  
 October 28 to 29.—Watford Camera Club. Entries close October 22. Sec., W. Branch, 100, High Street, Watford.  
 November 2 to 11.—Portsmouth Camera Club. Entries close October 24. Sec., F. J. Lawton, 20, Clarence Square, Gosport.  
 November 4 to 7.—Hackney Photographic Society. Entries close November 2. Secretary, Walter Seife, 70, Paragon Road, Hackney, N.E.  
 November 20.—Redhill and District Camera Club. Entries close November 7. Sec., J. Paterson, Ness House, Redhill.  
 November 23 to 26.—Lancaster Photographic Society. Sec., J. Holt, 11, Fern Bank, Lancaster.  
 December, 1908, to January, 1909.—Kiew International Photographic. Sec., S. T. Horovitz, Technical Society, Kreshchatik, 10, Kiew, Russia.

1909.

- January 6 to 27.—Northern Photographic (Manchester). Entries close December 11, 1908. Sec., S. L. Coulthurst, Broad Oak Road, Worsley, Manchester.  
 February 13 to March 13.—South London Photographic Society. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been received between September 21 to September 26:—

- DEVELOPMENT.—No. 19,782. Improvements in machines for developing, fixing, and washing photographic roll films. George Beattie Stoolie, 41, Reform Street, Dundee.  
 TANK DEVELOPMENT.—No. 19,845. Improvements in, and relating to, devices for use in tank development of photographic plates or films. Alexander Bruce, 96, Buchanan Street, Glasgow.  
 DEVELOPING APPARATUS.—No. 20,092. Improvements in photographic developing apparatus. Horace Handley O'Farrell, 61, The Avenue, Kew Gardens, Surrey.  
 COLOUR PHOTOGRAPHY.—No. 20,111. Improved screen or plate for direct colour photography and process for manufacture of the same. Société Anonyme des Plaques et Papiers Photographiques, A. Lumière et ses Fils, 31, Bedford Street, Strand, London.  
 ENLARGING.—No. 20,227. Improvements in photographic lantern enlarging apparatus. Arthur Gray Pickard, 6, Bank Street, Manchester.  
 SHUTTERS.—No. 20,292. Improvements in photographic shutters. William Savidge Akerman, 4, South Street, Finsbury, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

FILM DEVELOPING APPARATUS.—No. 1,327. 1908. A tank is fitted with a series of vertical compartments capable of supporting, edge

wise and separated from each other, a number of partially doubled films. The upper and lower ends of the compartments are arranged to allow of free circulation of the liquid and of the upper ends of the films to be withdrawn.

The apparatus comprises a holder A for the films and a receptacle B for the necessary solution. The holder A comprises a series of tubes 1, which may be formed by bending sheet metal blanks into the required shape, as shown in Figure 2. In this construction these tubes have two straight walls which form radii of a circle, the third wall being semi-circular, so that in cross section each tube roughly resembles the sector of a circle. One end of each tube is preferably provided with a projecting portion 4, whereby the stand

Fig. 1.

as a whole is provided with a series of supporting legs, or in some cases, where it is desired to render the stand reversible, these projecting portions may be formed at both ends of each tube. At the extremities of these legs are arranged stops 7, which, in the present instance, are formed by turning over and inward the end of the leg.

The object of the legs is to support the stand with the lower ends of the tubes well above the bottom of the receptacle or tank, a space being formed whereby through which the body of the liquid may circulate freely within all the tubes.

As the films are inserted in a rolled position their adjacent or vertical edges may have a tendency to curl or be otherwise deflected inwardly against each other. This action results in the sensitised surfaces of the films becoming scratched; moreover, the films no longer assume their proper erect position. It is to this

Fig. 2.

end that the radiating flanges, 6, are provided, since, when the up-right edges of the film which are adjacent to the central member of the stand tend to curl inwards, they are prevented by means of

the radiating ribs 6, and are so secured in their correct position and are prevented from coming in contact with each other. Kodak, Ltd., Clerkenwell Road, London, E.C.

**VIGNETTERS.**—No. 27,419. 1907. The invention consists of a vignetter in the form of a shallow case of cardboard, etc., with a large aperture in the upper cover. This cover carries a sheet of card or other material which can be moved in either direction, up or down, or across the negative or printing frame, and has in it an aperture smaller than that in the main cover. The shallow sides of the case fit on a printing frame, and the cover can be kept at a given distance from the frame. This is done by means of a strip of paper held to the under-side of the cover, and adapted to stand at different angles in relation to the cover. It is moved about a stiff hinge (e.g., of cardboard), and according to the amount this part is moved about its hinge (the lower edge of which will rest on the top of the printing frame), so will depend the distance the part containing the vignetting aperture will be above the negative. The movable part containing the vignetting aperture may be adapted to slide in between two sheets forming the cover of the appliance, the natural friction between the surfaces being sufficient to hold it in the position to which it has been adjusted, and at the same time enabling free adjustment to take place. William Lawrence Parkinson, Commutation Row, Liverpool.

## New Trade Names.

**GRAPH BRAND.**—No. 304,314. Nitrate of silver, chloride of gold, chloride of platinum, and other chemical substances used in manufactures and photography. Auguste Désiré Pennellier, trading as D. Pennellier and Co., 56, Gray's Inn Road, London, gold and silver refiner and manufacturing chemist. June 29, 1908.

**'XTRA SPEEDY.**—No. 305,462. Photographic dry plates. Wellington and Ward, The Elms, Shenley Road, Boreham Wood, Elstree, Herts, photographic material manufacturers. August 14, 1908.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Colouring Carbon Prints.

Carbon prints, if made in light pigments, may be coloured by either of the three general methods—namely, pastel, water colours, or oil colours.

In applying the dry or "pastel" colours (writes Mr. F. G. Palmer, in the "Amateur Photographer" for October 6, 1908), stumps are used, and with these a delightfully velvety appearance is obtained. The colours should not be applied thickly; one of the first maxims in colouring photographs must be, "Be moderate." A dusting of colour, which can be ultimately increased if necessary, is put on, and if there be any tendency to blow off or to come away too easily, the surface of the print can be made slightly more adhesive by gently breathing upon it. The edges of the colours may be readily fined off or left sharp, according to the exigencies of the particular case.

Water colours lend themselves without any difficulty or preliminary treatment to this form of work. The carbon surface is admirably suited to the process, and each successive shade may be worked on very easily and simply. Though not necessary, a sizing solution is sometimes applied, consisting of—

Isinglass .....	4 gm.
Water .....	100 cc.
Methylated spirit .....	100 cc.

This should be mixed in a flask or jar, and warmed in a saucepan of hot water until solution is complete. It should be put on the print with a wide, flat brush while still fairly warm, and, of course, allowed to dry before being used. This sizing is only applicable to papers which are very absorbent or have an extremely rough surface.

## New Books.

R. Dührkoop und die Neugestaltung der Bildnisphotographie  
Berlin: Otto von Holtzen.

A book about Dührkoop ought to be interesting, at any rate if it is illustrated as this is by his own work. And the excellent reproductions are the really interesting part of this volume, which is issued apropos of Dührkoop's completion of a quarter century in photography. The worst of the text is that it says a good deal of what other people in England and America have said of Dührkoop, but not very much of the man himself. However, we admit that Dührkoop to English eyes, and probably to German, is something very illusive. He has no fixed principle, no standard of beauty and style. To-day he delights in this, to-morrow in that, and he convinces you that he is a master of whatever method he may be using. Therefore, we must accept the text of the writer (Herr K. Wolf-Czapek) as the best account, short of personal acquaintance, which it is possible to give of the lively Hamburg photographer.

"Traitement des Residues Photographiques." By L. Mathet.  
Paris: Charles Mendel. Fr. 60.

Mr. Mathet's brochure of 30 pages quotes on its first page the figures of Davanne and Girard as to the small proportion—3 per cent. only—of the silver in the printing paper, which remains in the finished print, but it must not be forgotten that this result was obtained in 1864, and applies to albumen or salted paper. The modern emulsion paper does not yield so large a proportion of the precious metal to the residue collector, nevertheless M. Mathet's directions may be commended to those who prefer to have such instruction in the French language. The chapters deal with the recovery of silver from plates and papers, and of gold and platinum from papers.

"La Revue de Photographie." Paris: Le Photo-Club de Paris.  
Fr. 12.

In this volume we have the promised continuation of the monthly magazine carried on for some two years by a committee of the Photo-Club de Paris, composed of MM. Bourgeois, Bucquet, Demachy, and Puyo. The monthly issue has become yearly, but we hope will not become more infrequent still. The present volume evidences the same editorial policy which characterised the monthly—that is to say, there are plenty of examples of French and other pictorial work, and a few technical articles: not a word on the illustrative contents, which, like the cheese of the low comedian, is permitted to speak for itself. The pictures include some delightful work of MM. Demachy and Puyo, landscapes of the accomplished M. Missonné, some portraiture of Baron de Meyer, the strong sunshine effects of Guido Rey, and, in short, a pretty good representation of the Frenchmen and some other of the pictorial workers.

TELEPHOTOGRAPHY.—The current "Telephoto Quarterly," published and edited by Captain Owen Wheeler, from "Strathmore," Prince's Road, Weybridge, contains some most interesting notes and illustrations, showing the scope of instantaneous telephoto work in the way of seaside figure studies, wild birds, and distant architecture. The editor's article is on telephotography with small cameras. Our contemporary (5d. post free) continues to succeed in its task of recording practical progress in telephoto work.

## CATALOGUES AND TRADE NOTICES.

IS AN ANASTIGMAT WORTH ITS PRICE?—An oft-put question finds a most readable and instructive answer in the current issue of "The Prism," the tiny magazine of optics which Messrs. A. E. Staley and Co., of 19, Thavies Inn, London, E.C., publish in a semi-private way—that is to say, they send it to any one sending them one penny stamp for the postage. The current issue is particularly worth having.

BROMIDE ENLARGEMENTS.—Messrs. A. King and Son, trade artists,

of High Street, Littlehampton, send us their newly issued price list for the coming season, which we may recommend to those seeking good work in bromide enlarging and other branches at a moderate price.

## New Apparatus, &c.

A CIRCULAR TABLE SLIDE RULE.—Our contemporary, "Knowledge," has just issued a calculator for multiplication and division which should be useful to those having much computational work. It may be used for general calculations, for conversion of weights and measures, coinage, etc., or for the use of any special factor which its possessor has need to employ frequently. It is the design of Major B. Baden-Powell, and is issued at 3s. 6d. (postage 3d.) by "Knowledge," at 27, Chancery Lane, E.C.

THE NOS. 2 AND 2A "COMPOUND" SHUTTERS.—The new models Nos. 2 and 2A, of the "Compound" shutter have been fitted with alternating locking device for time and instantaneous exposures. Before the lens when fitted to shutter is a small plate bearing the initials "M. B. T." To work the shutter for the instantaneous exposures marked on the speed dial, the small button or knob should be placed at "M." In such case the setting lever on the right-hand side of the shutter should be set, and the speed dial adjusted to any of the speeds marked on this latter, when a pressure on the finger-release gives the exposure. If the automatic working of the shutter is required to be brought into play, the small knob or button should be placed at "T" or "B." In this case the finger-release or ball and tube may be used, when either time exposure or ball and tube can be made, or, when set at "B," bulb-exposure with finger or ball and tube. In this case the lever for setting for "time," marked on the speed dial, cannot be used, the shutter cannot be set when the button is placed on "T" or "B," nor can the finger-release for instantaneous work control when the button is set at "M." The alteration and improvement has been made to prevent accidental exposures, which sometimes take place when the finger-release inadvertently pressed, causing accidental exposure. By the improved construction this is entirely obviated.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, OCTOBER 10.

Liverpool Amateur Photographic Association. Excursion to Widnes.  
South London Photographic Society. Excursion to Croyhamhurst.

MONDAY, OCTOBER 12.

South London Photographic Society. "First Step in Architectural Photography." C. H. Oakden.  
Bradford Photographic Society. "Suggestions on Improving Prints, from Pictorial Standpoint." W. H. Womersley.

TUESDAY, OCTOBER 13.

Royal Photographic Society. Ordinary Meeting for the Election of Members.  
Birmingham Photographic Society. "Oil Pigment Printing." Demonstrated by J. H. Gear, F.R.P.S.  
Leeds Photographic Society. Social Evening.  
Hackney Photographic Society. "Carbon." Demonstrated.

WEDNESDAY, OCTOBER 14.

Leeds Camera Club. "Gloucester Cathedral." Harold Baker.  
Wimbledon and District Camera Club. "Development of Dry Plates." H. Matthews.  
Croydon Camera Club. "Autotype Carbon Process, and Oil Pigment Paper." A. C. Braham.

THURSDAY, OCTOBER 15.

Melbourne (London) Camera Club. "Old Printing Processes, etc." L. W. Ayer.  
L.C.C. School of Photo-Engraving, Bolt Court. "An Artist's View of Current Reproduction." F. C. Tilney.  
Liverpool Amateur Photographic Association. "The Caucasian Alps." Hermann Woolley.  
Handsworth Photographic Society. "Astronomical Photography." Frederick Smith.  
Richmond Camera Club. "Various Systems of Development." P. G. Payre.

## Commercial & Legal Intelligence.

A RECEIVING ORDER has been made in the East Kent Bankruptcy Court against Benjamin Knight (carrying on business under the name of Ben's Studio), photographer, of 58, High Street, Folkestone.

## Correspondence.

\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* We do not undertake responsibility for the opinions expressed by our correspondents.

### THE "GREAT CONGRESS" OF PHOTOGRAPHERS.

To the Editors.

Gentlemen,—Your wonderful report of the above would have afforded much better reading had you adhered to the truth, and a fair criticism, favourable or otherwise, would have been esteemed; but when it becomes needful for you to pen an article which bristles with fabrications it is only becoming that you should give the true facts to your readers, and offer an ample apology to those whom you have so basely traduced—namely, the promoters of the "Great Congress."

To take your article seriatim, you first take exception to the fact that the names of the committee were not published. Was this needful? I think not.

Your next point is, "It commences a hopeful paragraph with, 'The following trains will be run . . . ' but gives no trains." The actual paragraph reads: "Special excursions are being run by the following railway companies. For full particulars the reader is referred to the companies' bills and announcements, the trains mentioned being only a small proportion of those being run." Then follows a list of eight railway companies, beginning with the G.N.R., and no less than eighty-six cities and towns from which excursions were run are mentioned; an entirely different reading to that which you in your great kindness of heart put before your readers.

Now, as to your quibble as to the use of the word "congress," which appears to be your great stumbling-block. Wherein was this wrongly used? According to "Nuttall," a congress is a meeting of envoys, commissioners, deputies, etc. (please note the "etc."): Now, we had in attendance at the meeting envoys, deputies, or whatever other name you like to call them, from Liverpool, Northampton, Birmingham, and other large towns. Thus is the use of the word justified.

Had you stopped your quibble at this point I should have treated it with the silent contempt which it most undoubtedly deserves, but when you go on to say that the name of one of the gentlemen was used without his sanction and against his expressed wishes, I throw the lie back in your throat, and tell you that every gentleman whose name was used gave his full permission before it was added to the list; nay, more, I hold the written replies to my letters giving this permission, and these letters are open for either you or any other person to inspect if they are sufficiently interested to call at my address. Criticise as much as you like, but be fair, be honest, and, above all, be truthful.

The fact is, Gentlemen, that the "congress" was too great a success for you to fully appreciate it; you had, I suppose, never before heard of a gathering of over 1,500 photographers and their friends; you had never before heard of over 950 cameras being used at one place on the same day; you had never before seen between 500 and 600 photographers sit down to tea at one and the same time, with other sittings to follow.

Next time the L. and P. think of organising a "great congress," shall most certainly suggest that my committee first obtain your kind permission; but perhaps you were very short of cheap copy

last week and wanted to fill your paper, for I notice that the "congress" was worth nearly a page to you, fabrication as it was.

As to the report in the "Morning Post," with this I had nothing to do. The L. and P. certainly does not number 1,000 members. I wish it did, but it still grows.

I was once blest with two grandmothers, one of whom used to say to me, "What is worth doing at all is worth doing well," and the other taught me that "If I could not say what was good of anything to say nothing at all." What a blessing such grandmothers would have been to you.

I would, in conclusion, ask you to note that there is no "R" in my name, other than that in the word "Ernest."—Yours faithfully,  
ERNEST HUMAN.

43, Whitta Road, Manor Park, Essex.

[It would seem that an unfortunate choice of ancestors has deprived us of the power of refraining from criticism when criticism is needed. The author of the above letter (to go by his last paragraph) should surely exonerate us from blame. There is nothing in our report of last week which was not justified, and we have since reconfirmed what we said as to the twice-expressed wish of one individual not to be announced as a speaker. We withhold from the above letter one paragraph, which is unnecessarily personal.—Eds. "B.J."]

### THE INVENTION OF SELF-TONING PAPER.

To the Editors.

Gentlemen,—In your issue for April 20, 1906, page 319, Mr. D. Bachrach claims to have been the inventor of the now popular self-toning papers. In your succeeding issue, in a leading article, you confirm Mr. Bachrach's claim "to have been the first to have worked and published such a process." Quite recently, however, during a search through back files of the photographic journals, I noted that Ashman and Offord published in the "Photographic News" for July 24, 1885, the addition of auric acid to gelatino-chloride emulsions for "quickenning the toning process considerably." Apparently they did not recognise that subsequent toning was unnecessary; still this note antedates Mr. Bachrach's publication by about three years.—Yours faithfully,  
E. J. WALL.

Ealing.

### COUNTING SECONDS.

To the Editors.

Gentlemen,—Your editorial re "Counting Seconds," was very interesting, but though passably musical myself your musical method does not appeal to me as accurate enough. I prefer to stand with feet slightly apart and gently rock from foot to foot; it is quite easy this way to convert oneself into an accurate pendulum. I have often counted to a full minute in this way, quite correctly—to another's testing, I mean, and without seeing the watch-face myself, of course. This is the method I invariably use when testing light by the invaluable "Watkins."—Yours faithfully,  
FREDERICK H. EVANS.

32, Rosemont Road, West Acton, W.

October 2, 1908.

To the Editors.

Gentlemen,—Being a subscriber to your valuable paper, I was naturally interested in your remarks respecting an article of mine on counting seconds by music appearing in the September "Photographic Monthly."

You suggest that a waltz tune would be not so variable in tempo as a march. In this I must beg to differ from you. I may say I have some claim to being a musician, and know several men who earn their living wholly by playing at dances, etc., and they say some people dance waltzes very slowly, whilst others, notably military people, dance waltzes very quickly.

I think you will agree that the two bars drum solo, which precedes the tune proper of a band playing on the march, varies but very little. In fact, I have since learned that the regulations set out in the manual issued by the Army Council for infantry training state that a quick

march (that is, of course, normal march time) should be 120 paces to the minute, that is half a second to each step, or a second between, say, the left foot and the left foot again. The regulations further stipulate that a pendulum, or, in other words, a musical metronome, should be used to accurately time the paces when drilling recruits.

You advocate for quarter seconds setting shutter at bulb and squeeze and relax as quickly as possible. This I do for an eighth of a second. Moreover it depends upon the flexibility of one's hand as to how quickly they can open and shut it. A man who is used to playing the piano would naturally have his hand more lissom than a man who did heavy work.

For half-second you recommend setting the shutter at time and squeeze and relax as quickly as possible. I have tried this, and can give a quarter of a second easily, so I think you must agree it would be much easier and more accurate to imagine the time between two paces in march time for half a second. For both your methods of quarter and half-second I should be giving only half the exposure necessary if I followed them.—Yours very faithfully,

59, High Street, Whitstable, ARCHIBALD H. DODMAN.  
September 29, 1908.

### THE "ILLUSTRATIONS BUREAU."

To the Editors.

Gentlemen,—I notice in your replies to correspondents in last week's issue you state that to the best of your belief the "Illustrations Bureau" is dead. If such a report has reached you, perhaps you will permit me to point out that it is much exaggerated; it is not even in a moribund condition, but at its old address—which you can find in any directory or telephone book—it carries on what is undoubtedly the biggest photographic press business in the world. Its pictures are to be seen in all the important weekly papers and magazines both in the United Kingdom and in every foreign country where photographs are used as press illustrations. Perhaps it is that the gentleman who replies to correspondents does not see the illustrated weekly papers, or he would have seen the "Illustrations Bureau" as the most prominent source of supply.

Believe me, Mr. Editor, we are very much alive.

I remain,

Yours faithfully,

BERNARD ALFIERI,

Illustrations Bureau, 12, Whitefriars Street, London, E.C. Manager.

October 7, 1908.

[We can assure Mr. Alfieri that the error arose from the confusion of the name of the business under his direction with that of another no longer existing, and not from the least doubt in our own mind of the magnitude and activity of the "Illustrations Bureau." Our apologies are due both to Mr. Alfieri and to the querist whom we have unwittingly misled. We cannot visit the office of the "Illustrations Bureau" in Whitefriars Street without feeling that an obituary notice of that business is the most remote of our editorial duties.—Eds. "B.J."]

**PORTSMOUTH CAMERA CLUB.**—The annual exhibition of the above club (formerly known as the Southsea Photographic Society) will be held at 5, Pembroke Road, Portsmouth, from November 2 to 11, inclusive. There will be two open classes, one for prints and one for lantern slides, and in these the awards will take the form of silver vases. Exhibitors at the Southampton and Hove Exhibitions can have their exhibits forwarded to Portsmouth free of charge, and at reduced entrance fees. Further particulars and entry forms may be obtained from the secretary, Mr. F. J. Lawton, 20, Clarence Square, Gosport.

**SCREENLESS PHOTO-ETCHING, LIMITED.**—Capital, £10,000, in 9,900 ordinary shares of £1 each and 2,000 deferred shares of 1s. each. Objects: To carry on the business of printers, publishers, photo-etchers, etc. Minimum cash subscription, 20 ordinary shares. The first directors (to number not less than two nor more than five) are R. Bain, C. Walkden, and C. F. Cazenove. Remuneration, 10 per cent. of the profits available for dividend. Registered office, 5, Henrietta Street, Covent Garden, W.C.

## Answers to Correspondents.

\**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*

\**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

\**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*

\**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

H. S. Franks, 60, West Strand, London, W.C. Four Photographs of Miss Mabel St. Clair.

A. G. Meakes, 12, Victoria Street, Rusholme, Manchester. Photograph of the Manchester New Infirmary.

W. Hampton, 195½ Argyle Street, Glasgow. Photograph of a Wonderful Freak Malformation Child.

ANXIOUS.—T. S. Bruce, 4, Villas-on-Heath, Vale, Hampstead, N.W.

**COPYRIGHT.**—I have some postcard photographs of self and friends, taken while on my holiday in the country by a local man who sells them. My friends want some copies of same larger, which I can do myself. Have I the right to do so without his consent?—**ENQUIRER.**

Unless an order was given for the groups you have no right to copy. If the photographer has, as seems to be the case, the right to sell copies, no one else has a right to copy or enlarge the photographs.

**MERCURY.**—(1) About 1,000 hours' use. (2) New electrodes, which would appear to be necessary, would cost as much as a new tube. Better write A. W. Isenthal and Co., Mortimer Street, London, W. W. M.—We are sorry we have no information beyond that already published.

**LENS QUERY.**—In your next issue I should be pleased if you would say what value a lens might be by Vogel of Philadelphia, half-plate portrait, about 8 in. focus, Waterhouse stops, working at about F5, and working in rack focussing?—**LENS CAP.**

We do not lay ourselves out to value apparatus. Your best way will be to try the lens and then judge the value it would be to you in your business. Its market value is probably a few shillings.

**SPOTTY PRINTS.**—Will you kindly inform us what is the cause of the spots on enclosed prints? The process, roughly speaking, was:—Developer, metol soda, hypo, with a little acetic and alum wiped over with weak ferricyanide, washed well twenty minutes, dried by heat.—**PRINTER.**

The spots are clearly due to want of care in the work. Some particles of foreign substance have been allowed to come in contact with the prints while they were in a wet condition. This is shown by the spots having a well-defined nucleus in the centre.

A. T. W.—(1) If the facts be as stated by you we should say that you were justified in refusing acceptance of delivery of the cards. (2) The firm can, of course, sue you, but whether they will succeed is quite another matter. (3) If you are sued you will have to instruct your solicitor to defend the action. This seems a case that the Professional Photographers' Association could amicably settle for you.

G. Q.—The prints enclosed are certainly about as bad as they well could be to be supplied for sale. You will be quite justified in refusing to accept them. As you have already paid you should demand the money, and negatives, back. If it is refused, sue in the county court.

**LENS QUERY.**—Could you tell me the maker and about the value of the following:—12 x 10 "Extra Rapid Euryscope," iris diaphragms. There is a small brand on the flange (as enclosed sketch); there are only two glasses in the lens (one in front and

at back); the diameter of these glasses is about one inch each and about a quarter-inch thick. Will be much obliged if you can inform me from above description.—E. W. L.

From the description we can tell you nothing about the make of instrument. We can, however, say that it is not what is generally known as an "Extra Rapid Euryscope," and that if it will cover 12 x 10 it must be a very slow one, as the glasses are but 1/4 inch in diameter. Euryscope lenses of ordinary rapidity for 12 x 10 size have an aperture of about 2 1/2 inches, and the extra rapid ones are much larger. The value of such a lens is very small indeed.

INTAGLIO PRINTING.—I should be greatly obliged if you could give names and addresses of intaglio firms who work for the trade in photogravure, and particularly half-tone intaglio, those who are accustomed to do a fairly good postcard or similar print.—R. A. LYNCH.

The Rembrandt Photogravure Printing Co., Lancaster.

CAMERAS.—I see dry plates 6 in. x 4 in. are now in some makers' catalogues. Will you please say whether you know of any camera at size now on the market, and if anything is on foot to introduce as a standard size? The plate, if held in the dark slide by the ends, will cut a full cabinet, and gives plenty of room to centre postcard. Print from a plate taken in a camera that size enclosed. C. W. R. E.

Our notice has not been drawn to cameras of this size, and we cannot name one offhand. We doubt whether the present vogue for the half-plate size will encourage manufacturers of either plates or papers to take up the 6 x 4 size.

W.—If you sold the rights to reproduce to the company the matter is obviously within its rights in disposing of the latter as it sees fit. We cannot see that you have any legal ground for complaint. You must have supposed that the sale of the cards would be by local tradesmen.

P. P. A. (Kathiawar, India).—All gelatine plates are at a disadvantage when worked at a shade temperature of from 100 deg. to 105 deg., unless everything is cooled artificially. You mention that you want plates that will stand 110 deg. Fahr. We cannot say that we know of any makers who would guarantee their plates bear that temperature unless very special precautions were taken. However, we should think that most brands of English plates might, with care, be manipulated at 100 deg. to 105 deg. Fahr. by the use of a bath of chrome alum after the developer or of a chrome alum fixing bath as given in the "Almanac." A bath of formalin before development might help matters, though we fear the high temperature would make its use almost prohibitive.

CLASS BICHROMATE.—(1) Would you kindly tell me whether it is possible to obtain bichromate of potassium in a clear state—that is, colourless, or nearly so—without destroying its properties and union upon gelatine? For a certain purpose I wish to get rid of a strong yellow, but I suppose it is impossible without altering chemical properties. (2) Also, could you tell me how formalin is made (in brief), and whether it is poisonous?—METAMORPHOSE.

(1) It is impossible to do what you want without converting the bichromate into something else—e.g., a chromium salt—but then it would not have oxidising properties. If you require a nearly colourless oxidising agent you might try chlorine water. (2) Formalin is a solution in water of formic aldehyde. The latter is made by the oxidation of methyl alcohol, the vapour of this latter compound being passed, mixed with air, over spongy platinum. Formalin is not highly poisonous, but is an irritant.

FRAM LANTERN SLIDES.—I wish to make lantern slides from printed matter, showing white letters on a black ground (on the lantern screen), and am using process plates direct, afterwards cutting them to lantern size, but cannot get sufficient density without veiling the letters, which should remain almost clear glass. Is it not possible to do this without intensification, as I find any slight veiling is only accentuated by this process? What developer would you recommend giving excessive contrast, and, if necessary, what intensifier?—DENSE.

There is no better developer for this purpose than hydroquinone and caustic soda, as given in the "Almanac" for Thomas's plates. A good plan is to over-develop somewhat and reduce with strong Farmer's reducer, rubbed over on a wad of cotton wool. If this is used until the lines are practically clear when the negative is

laid face down on a piece of paper, it will be best not to intensify, although mercury and ammonia is the best for the purpose, if any be employed. See the article in the "B.J." for July 31.

MRS. J. A. D.—We suggest you apply to one or two retouchers for their charges for similar services. The prices vary, but we should say £1 for ten or twelve lessons, about an average.

LILLY AXWORTHY.—There are many possible causes of spots on collodion paper, and we should advise you to look up the "B.J. Almanac" for 1907, page 786. A very common cause is drying with blotting-paper that has been used before, and is therefore slightly contaminated.

G. H.—The markings appear to us to indicate that the gelatine is decomposing. We have seen similar effects before on old negatives. The only course we can advise is to make a copy of the negative on a fresh plate. We doubt if external damp is the cause, as a properly varnished negative should be quite damp-proof. If, however, the negative is not properly dried before varnishing an effect such as this might be readily produced.

VERITAS.—Such a series of exposures would be impossible, in our opinion, for anyone working single-handed.

P.O.P. TONES ON POSTCARDS.—As I am wanting to do a great deal of publishing postcard work could you favour me with the formula and working instructions for obtaining on bromide cards the effect of silver prints, as obtained by postcard publishers?—TONER.

Most of the commercial toned bromides on the market are done with hypo-alum, the action of which is very satisfactory with a paper suitable for the process.

COPYRIGHT QUERY.—I photographed a cricket club, and to get the privilege I had to give a picture value 25s. to the club, on condition no one else photographed them. I have been selling pictures and also postcards. Now I find somebody has sent a postcard away and got an enlargement done, a shade under my price, and is quite probable they may get a good many more. Will you answer if giving this picture makes my photograph copyright, and can I take action against this photographer?—ANXIOUS (Accrington).

The copyright in the picture is yours, but as you have probably not registered it you cannot take action against anyone. If you register it now you can prevent further copies being made from the picture, though you can recover no penalties for what has already been done.

RESIDUES.—Will you kindly give your valuable information—viz., what quantity of liver of sulphur do I put, say, in 80 oz. of hypo? I save in order to get the sediment (silver), which we want.—VANDYKE.

It is impossible to say without knowing how much silver there is in the hypo. The best way is to add the sulphide of potassium until it ceases to cause further precipitation, then you will know that all the silver has been thrown down.

A QUESTION OF INFRINGEMENT OF COPYRIGHT.—I have bought some (china?) figures at a shop, and intend to photograph them and home-made surroundings, scenery, buildings, etc. They are "made in Germany," and the box containing them is so marked. I intend sending the prints to an illustrated paper. Can I do so without risk of copyright law? I have seen toys treated so, and these are similar ornaments.—TORS.

In doing what you propose you will not be infringing the Copyright Act in any way, and you can, if you like, make the pictures copyright.

STAINS ON NEGATIVES.—We have one or two valuable negatives which, owing to carelessness on our printers' part, were put out printed in a damp state, and consequently are badly stained. Is there any remedy for removing silver stains without injuring the negatives?—S. A. C.

Some stains are very difficult to remove, and some cannot be removed at all. About the best remedy we can prescribe is as follows:—Soak the negative in potass iodide, 200 grains; water, 10 ounces; and, after washing, put into potass cyanide, 300 grains; water, 10 ounces; then rub the film with a fledge of cottonwool. If this does not get rid of the stains try one of the other methods.

BROMIDE.—We will reply to your query next week.

DELAY IN EXECUTION OF ORDER (J. DOUGLAS).—All we can suggest is that you write to the effect that if the new slides are not sent

forthwith you will proceed in the county court for return of the money you have paid and the value of the pattern slides; also for damages for their detention.

**ELECTRIC LIGHT.**—Please advise us through this week's "Journal" on the following:—We propose taking premises for portrait work. The size of studio would be 24ft. x 11ft. x 31ft. 6in. high, and shall have to rely entirely on artificial light. Would the light, viz., 8ft. 6in. be sufficient for producing good work, and should you think that one lamp (we think of having Houghtons' Jandus) would be sufficient, or would it be advisable to have a pair? We are rather concerned about the light, as we have a recollection of an article in your journal saying a considerable light was required for good work.—**BRIT.**

One light may be used with suitable reflectors. But it would be better to have two for work in the way of groups, and on the score of shorter exposure in single portraits also.

**VARIOUS.**—(1) Would lead or zinc be suitable for the lining of home-made trays for developing and fixing of plates? (2) Also, would it have any deleterious effect on prints, collodio-chloride, P.O.P., etc., and also on bromide papers, providing, of course, that separate dishes were used, and that the solutions are not left standing in the dishes? (3) Where can I obtain rubber sheeting for lining toning trays, and what is the usual price of same? (4) Can you give me a formula for stripping films from the glass? I have used the hydrofluoric acid, but it is difficult to obtain, and a chemist once gave me a formula which, when made up, answered the purpose very well, and he told me that the constituents formed hydrofluoric acid, but I have lost the formula. (6) I have seen several formulæ for gold and sulphocyanide toning of bromides, gaslight papers, etc.; would these be applied to the sulphide-toned prints after a thorough washing, or does it apply to the black print without any sulphide or alum toning?—**T. HOPKINS.**

(1) The usual photographic trays would be preferable to either. Zinc will certainly not do for hypo solutions, as it would soon be destroyed. (2) Yes. Unprotected metal must not be used for papers containing free nitrate of silver. (3) At any of the india-rubber shops. Its price varies according to its thickness and quality. (4) Fluoride of sodium 60 grains, sulphuric acid 1 drachm, water 1 pint. (5) Dorritt and Martin and others. See our advertisement pages. (6) If used on the black prints the toning action is slight, and gives a blue-black colour; if applied to the sulphide-toned prints red chalk tones are produced. See the current "Almanac," page 652.

**HOLIDAYS.**—I have been in my present berth for eight months, and last week I asked for a fortnight's holiday. My employer replied that he did not, as a rule, give holidays, but he would arrange that I could take one if I liked, but that I must not expect him to pay me while I was away. I should like to know, and I shall be much obliged if you will tell me, what is the rule in the photographic business with regard to holidays. Are not some compulsory under the Factories Act?—**RETOUCHER.**

Yes, the statutory Bank Holidays and a few half-days during the year. In reply to the other query, there is no set rule amongst photographers with regard to holidays. Some give a fortnight, some a week, and some none at all. Where holidays are given it is customary that the employee is paid his, or her, wages the time. Unless that were done the holiday would be much discounted. Usually in establishments where holidays are given it is only to those who have been in the employ for a full year or more.

**C. A. S.**—The combined bath containing hypo, alum, lead, and gold is not to be recommended to the novice if permanence in the pictures toned in it is a consideration, and for the reason that long after the bath has been exhausted of its gold it still continues to tone and yield as good tones as it did before. Under these conditions the novice continues to use it, although the tones then are obtained by sulphur toning and not by gold. An experienced hand, if he used the combined bath, would discard it so soon as it was known that all the gold had been used up. For ourselves, we prefer separate toning and fixing, although it entails a little more trouble.

**Mac.**—In copying a cabinet picture the same size as the original the lens must be midway between the latter and the focussing-screen

of the camera. If your camera will not extend far enough you will have to use a "cone," or elongating piece, to carry the lens. The alternative is to use a shorter focus lens that will cover the size of the negatives.

**J. BEDWELL.**—What you describe as the extraordinary appearance of the negatives is due to hyposulphite of soda crystallising out of the film. Had the negatives been more carefully washed they would not have had the "extraordinary appearance." More care in future will avoid it.

**VINCENT.**—The most convenient furnace you can get for firing small enamel plaques would be one or other of the gas furnaces supplied by Messrs. Fletcher and Co., of Warrington. They are not at all costly. Doulton's, Lambeth, we think, also make suitable gas furnaces for the work.

**ANNOYANCE.**—My studio is on the ground floor in the garden. No door is a small school, and when the children come out for their play hour they cause great annoyance to sitters by looking and sometimes laughing and making grimaces at them. I have complained to my neighbour and he says he has forbidden the children to get on the wall, but the nuisance still continues. Could the police interfere?—**STUDIO.**

No, such a thing is not within its province, but it surely is a very easy matter for you to put a stop to the nuisance. All you have to do is to put fluted or ground glass in the side of the studio.

**SMOKING IN DARK-ROOM.**—Is smoking in the dark-room likely to cause fogging of the negatives? Several times of late I have had them fogged through no apparent cause, unless it be tobacco smoke. I may say that I almost always, while developing, have a pipe or cigarette in my mouth.—**FUMA.**

We have never heard of tobacco smoke causing plates to fog.

**A BUSINESS AFFAIR.**—We should feel under an obligation to you if you would enlighten us on the following. My brother and I have been in business at the above address for eight years. Three years ago we bought a small business at —, and engaged an operator and manager for it. The business has now grown to be a good one. A month ago he gave us notice, and has since left. When he gave notice we offered him more money to stop, but he would not do so. We now learn that he has taken a shop in High Street and is building a studio at the back; the money, we are told, is being lent by a tradesman in the place. We wish to know is whether there is any law that will prevent his opening a business in the town, seeing that he was three years in our employ and is better known in the business than either of us. Also, can he be prevented from using our name on circulars and shop front?—**S. BROS.**

Unless you have an agreement to the contrary, there is no law to prevent the man from acting what he is. He has a perfect right to commence a business on his own account, and it would be his fault if he had not—notwithstanding that his doing so may probably materially injure you. He is also entitled to use your name, provided that he does not place it more conspicuously than his own in such a way as to lead the public to believe that you are connected with the new business, or that it is yours. He may say for Messrs. —, or say three years manager to Messrs. —, anything of that sort, so long as his name is the most conspicuous.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

is day (Friday), October 16, marks the closing of the "British Almanac," 1909, for the press.

an exhibition of multi-colour prints by the Brothers Hofmeister H. W. Müller remains open at the house of the "B.J." until day week, October 24.

photographer was fined £5, with the alternative of forty days' imprisonment, at Dundee last week, for working a scheme consisting combination of the issue of football coupons and the making of nit enlargements. (P. 800.)

death is announced of Professor von Jan, by drowning, while holiday in the Scilly Isles. (P. 801.)

conclusion of the article by Dr. C. E. K. Mees on photography coloured objects deals with certain specific cases in which the of a colour-sensitive plate and suitable screen proves of immense value. (P. 788.)

methods of manufacturing colour screen-plates and of copying one screen-plate on to another, figure, among other items, in the of the week. (P. 795.)

6 x 4 size and "Thames" colour plate appear, with other under "Correspondence." (P. 802.)

arrangements are far advanced for the holding of the sixth Scottish at Wishaw in January next. (P. 786.)

report of the exhibition of the Southampton Camera Club is on page 794.

Birmingham Photographic Society have moved into new rooms Exchange Buildings, New Street. Their occupancy was inaugurated recently by the Lord Mayor, and the society would appear to be showing its vigorous life. (P. 793.)

carbon process is the most suitable for the transfer of photographs to ivory for colouring. Some necessary details are mentioned on page 786.

precautions necessary when using a focal-plane shutter at a narrow aperture of slit are mentioned on page 785.

## EX CATHEDRA.

**Matt Varnish.** At the present time matt varnish is being largely employed as a means of improving negatives. It is sold by all the large dealers, and the formula for making it has appeared regularly for several years past in the ALMANAC. It is there mentioned that the proportion of the benzole used determines the character of the grain—the smaller the proportion the finer will be the grain, and the larger, the coarser will be the grain. But there is a limit to this, for if too much be used the resins will be precipitated. It must be understood that although the two resins—sandarc and mastic—are soluble in ether, they do not dissolve in benzole. It is the ether that holds them in solution, while the benzole has a tendency to precipitate them, which it will do if added to excess. The following formula for the varnish is the same as that in the ALMANAC, but is given in a more convenient working form:—

Picked sandarc	...	...	1 ounce
Mastic	...	...	100 grains
Ether	...	...	10 ounces
Benzole	...	...	2 to 8 ounces

There is a wide margin here in the proportions of the benzole, and the quantities given may be taken as the maximum and minimum that can be successfully employed. The sandarc and mastic are first dissolved in the ether and the extraneous matter allowed to subside, or the solution may be filtered. The benzole should be the pure No. 1 benzole, the coal-tar product, and not the petroleum spirit known as benzoline. It should be added a little at a time and well shaken between each addition. It will be noticed that each addition will cause a turbidity in the solution, but this will disappear on shaking. In making the varnish it is well to test it, after each two or three additions of the benzole, by pouring a little on a clean glass plate. Sandarc, like most resins, varies somewhat in its characteristics, and some samples may require more or less benzole than others.

## The Movement of the Focal-Plane Slit.

In using that very popular form of hand-camera, the focal-plane folding camera of the Anschütz or Palmos type, many fail to realise that the camera can be held in either of four positions, so that the blind may run either up or down or from right to left. As has often been pointed out before, when a narrow slit is used at a moderate tension various degrees of distortion may be produced in the image of a moving object, according to the direction in which the slit runs, but the direction of movement also has an important bearing upon exposure, which fact should be borne in mind when dealing with fast moving objects. When the image and the slit are moving

across the plate in opposite directions the exposure for the moving image is shorter than when they are moving in the same direction, therefore there is less chance of movement showing in the result. Stationary objects, of course, get the same exposure in either case. This applies to slits of any width, and the point is of considerable importance when very rapid movement is in question. One must, however, be careful to remember that the image moves in the opposite direction to the object itself, therefore, to attain the shortest exposure possible we should always make the slit move in the same direction as the object. It may be objected that when the camera is turned so as to make the slit move in the direction desired the finder may become useless. It will, of course, often get into a position in which we cannot use it, but in photographing rapidly moving objects a small finder is of little or no use according to our experience. It is quite easy to aim straight without it, while it is next to impossible to snap a particular phase of a movement if we pay any regard to the finder at all.

\* \* \*

#### **The Scottish Salon.**

The prospectus and entry form for the sixth annual "Scottish" are now available, and may be had on application to the Salon Secretary, Robert Telfer, 138, Glasgow Road, Wishaw. This exhibition, it might be remarked, is really the only "national" photographic exhibition in the world; it is confined to photographers in Scotland and Scots "ayont the Border," and in this connection it is interesting to note each year the increasing number of Scots now located outside Scotland who are represented at the Scottish. There are no entry fees and no medals, hanging being the only award of merit, and getting a place on the walls is becoming increasingly difficult. At the last "Scottish" in Aberdeen about 300 were hung out of some 1,000 entries, and it is expected that Wishaw, with its central position, will top the Aberdeen entries. Alex. Keighley, Arch. Cochrane, and R. Clouston Young, R.S.W., form the Board of Selection this year; this is a new board altogether, although Messrs. Keighley and Cochrane have at different times served as jurors. Great preparations are being made at Wishaw; some thought it was rather ambitious of the folk there asking the Salon to visit their town, but they are determined to give their visitors a right hearty welcome. The Provost is at the head of affairs, and every one seems anxious to work for success. The perambulating nature of the Salon draws in each year a new set of workers and thus widens the sphere of interest. As usual, an Art Union will be run in connection with the exhibition, and this has been the means of selling a

considerable number of the exhibits. Entries close December 7, receiving date for pictures is December and the exhibition will remain open from January 1 to

#### **PHOTOGRAPHS ON IVORY FOR COLOURING**

On several occasions of late we have had to reply to correspondents with reference to the production of photographs on ivory, such as: How they are made—Where ivory is to be obtained—What colours are employed in colouring of them—Where obtainable—and similar queries. As the replies given in the "Answers" column must necessarily be brief, we shall here give working details for producing photographs on this material. We do this especially because at the present time highly finished miniatures are being made such a special feature of most of our leading portraitists. Ivory, it is well known, is the best and most pleasing material for the miniature painter to work upon, and on it effects are to be obtained which cannot be got on any other substance.

The idea of producing photographs on ivory dates back to the very earliest days of the art, and some fifty or more years ago patents were applied for in connection with this class of work. They were all, however, based upon similar methods, transferring collodion or albumen films to ivory, and none of them came into practical use. It may be thought by some that if the ivory were salted after the manner of paper, then sensitised with nitrate of silver and afterwards printed, that a photograph could be obtained. And so it could; but there would be no whites in it, and the grain of the ivory would be very conspicuous in the finished picture, so that it would be useless for colouring upon. That is due to the varying porosity of the ivory absorbing the solutions unequally.

The only successful way, up to the present, of producing photographs on ivory is by the carbon process—by the double transfer method. If the single transfer be used, the laterally reversed negative must be employed, and, furthermore, the ivory is stained by the bichromate in the time when the latter is squeezed upon it, which stain cannot afterwards be discharged.

Ivory, suitable for the purpose, is supplied by all art colourmen in various sizes. In the smaller sizes it is at all expensive, but as the size increases the prices increase very materially—quite out of proportion to that of smaller pieces. In purchasing the ivory, the whitest, that freest from grain, should be selected. As sold, it is supposed to be ready for the use of the miniature painter, but such is not always the case. It may appear free from scratches when bought, but if it be immersed in water

#### **THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1909.**

Edited by GEORGE E. BROWN, F.I.C.

THE forty-eighth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of over 1,000 pages, and the entire edition of 25,000 copies was sold out immediately. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1909 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

#### **REFLEX CAMERAS,**

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the

ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1909 will be modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1909 will appeal to photographers the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and, wherever practicable, new features of an informative nature will be added.

**NOTICE—IMPORTANT.**—Our publishers ask us to inform agents that it is advisable to place their orders for copies immediately, as over half the issue is already booked, and a second edition will not be printed.

while it will often show some fine scratches that were previously visible. These must be got rid of, otherwise they will be more pronounced in the finished picture. This is done as follows:—Some cuttle-fish powder is tied loosely in a piece of fine muslin, the ivory is wetted with water, and a little powder dusted on. Then, with a soft cork, the surface is worked over until the scratches are removed. In doing this the cork should be used in one direction only—that of the grain of the ivory. The latter is then well rinsed with water and allowed to dry, when it will be ready for use.

It will be as well now to say something with reference to the negatives that are best suited for carbon pictures on ivory that are afterwards to be highly finished in water-colours. Usually, pictures on ivory are reductions from larger ones, so that it is easy to make the negatives of the character best suited for the purpose. It should be somewhat thin and delicate. If it is of a very strong and vigorous nature the print will be strong and vigorous too, consequently the shadows of the picture will be in considerable relief, a very undesirable feature in a highly finished miniature. Moreover, if in the colouring gum is heavily used on the shadows to give them transparency there is the possible—perhaps rather remote—danger, if the miniature is subjected to a long-continued dry heat, say such as that of the tropics, of the gum and the thick plate splitting off the ivory in the deep shadows. With regard to the colour of the tissue used, it is very much a matter of taste, as some artists prefer one colour to work upon and some another. One gentleman we knew always preferred for colouring prints those that were of a light reddish-brown colour, because, as he told us, they saved him much time in the finishing. Whatever tissue be selected it should be but lightly printed, so that it may be developed in moderately cool water. If darkly printed it will give trouble to the colourist, as some of what should be the high-lights—or almost bare ivory—will probably have to be scraped away.

The print must be developed on the usual flexible support. The one best for our present purpose is a piece that has been used several times for transferring to paper. After development the print should be well washed to ensure the complete removal of all traces of the bichromate, so that the ivory does not become stained. The print is then put into a weak solution of alum for a few minutes and again well rinsed and allowed to dry, when it will be ready for transferring to the ivory. That is done as follows:—The print on its support is soaked in cold water for about ten minutes, or until both have become somewhat pliable. It is then, with the ivory, immersed in a solution of gelatine made as under:—

Nelson's No. 1 gelatine .....  $\frac{1}{2}$  ounce.  
Water ..... 8 ounces.  
Chrome alum (dissolved in 2 ounces water) 8 grains.

Both solutions should be made tolerably hot before they are mixed, and the alum solution should be added slowly with vigorous stirring. The hot mixture is then strained, through a double thickness of fine muslin, into a warmed dish. For convenience in working it is well to trim the print on the temporary support a trifle smaller than the ivory to which it is to be transferred. The two are next brought into contact—face to face—in the solution, avoiding air bubbles, and then well squeezed together on a glass plate so as to expel as much as possible of the gelatine, and thus leave the surface of the ivory as free of it as is possible. The picture is now allowed to dry. When quite dry, the support is stripped off, and the picture will be firmly attached to the ivory. If it were attempted to colour the picture in the state in which it now is, it would be found to repel the colour and seem to have a greasy surface. This is due to a trace of the waxing compound of

the support remaining on the surface. This, however, may be removed with benzole and a pledget of cotton-wool. The picture is now finished and ready for the colourist.

With regard to the colours used for painting on ivory, they are the ordinary water-colours as sold by all artists' colourmen, and the finished picture, of course, depends entirely upon the skill of the artist who does this important part of the work.

#### FINENESS OF GRAIN AND MICROPHOTOGRAPHY.

A COMMUNICATION from a correspondent this week suggests that something of interest may be said with reference to the character of the grain obtainable in the photographic image. It appears our correspondent is anxious to produce micrographs that will stand high magnification under the microscope without showing excessive granularity of the image. He also refers to the good results obtained by the late Mr. Dancer and others many years ago, when these tiny pictures were regular articles of sale by opticians and others who made a feature of objects for the microscope some fifty years ago. One of the first, if not the first, to produce these little pictures—though not for sale—if we mistake not, was the late Mr. Geo. Shadbolt, for some years editor of this "Journal." From some examples of his work we have seen, we may say that nothing since has been done that eclipses, even if it equals them.

Although these minute pictures, which seem a mere speck on the glass, are looked upon more in the light of curiosities than anything else, they may at times prove exceedingly useful. For example, during the Franco-German war, when Paris was so closely besieged, the only way of communicating with the outer world was by means of the "pigeon post," which was placed in the hands of M. Dagron, who had long been identified with the production of microphotographs, mounted on the surface of a small Stanhope lens. The communications were written, with the addresses, boldly on paper. A number were then affixed to a board, or screen, and a negative made of the lot. From this a minute transparency was made on a wet collodion plate, and the film stripped off. A number of these films, which only weighed a few grains, were then rolled up and put into a small quill and attached to the carrier pigeon's wing. When the pigeon arrived at its destination the films were flattened out and the images projected on a screen by an enlarging lantern. The communications were then read and re-written, and afterwards forwarded in due course to those to whom they were addressed.

Now it is manifest that in order to produce microphotographs the particles of silver forming the image must be in an extremely fine state of division, otherwise it will not be readable under great magnification. By way of illustrating this, most persons have seen on the embankment at some railway stations the name of the place formed by large chalk flints in letters six or eight feet long, which are clearly readable; but if the same size stones were attempted to be used for letters, say, two feet long, the result would be failure, as they would be too large to form them legibly. So it is with a coarse grain in a very minute photograph. Seeing that for this work the reduced silver must be in the finest possible state of division, we shall now consider how that is to be obtained, for it is obvious that it is of no use to employ a high-class objective for the work if the definition it yields cannot be rendered by the photographic film.

At once it may be said that gelatine plates are useless for the purpose. It is true that with some lantern plates the reduced silver is in a comparatively fine state of division: but if a small micrograph, such as are now being referred to, be made on such plates, the grain will

appear very coarse under the microscope. This might well be expected when it is considered that with this process the particles of bromide of silver are practically held in mechanical suspension in the gelatine. In the collodion process, however, the fineness or coarseness of the particles in the developed image depends very much on conditions. For instance, a bromo-iodised collodion, sensitised in an acid bath, and developed with the usual iron developer, will not yield so fine a deposit as will a simply iodised one, without bromide, sensitised in a neutral bath, and developed with pyrogallie acid. The latter method of working is somewhat more difficult for the novice, because, to get the best results, everything must be almost in a state of equilibrium, which the slightest disturbance may upset.

It goes without saying that the collodion used must yield a film that is perfectly structureless. The sensitising bath should be neutral, and the developer freshly made. Under these conditions the reduced silver will be in an exceedingly fine state. One point, however, is essential, which is that the exposure must be full, and must be made in a good light, for it is found that under these conditions the image partakes more of the character of a stain than an actual deposit of particles of silver. The image then has a warm claret tint—that is, when the developer is acidified with acetic acid only; it has a colder tone if, in addition to the acetic, it contains a small proportion of citric acid. If the exposure is made in a bad light, even when an equivalent time is given, the character of the developed images is different—the colour is much colder: also the particles of reduced silver are coarser. The silver bath should be the usual thirty-grain strength, and must be saturated with iodide of silver. Before the developer is applied it is well to drain off the superfluous silver bath as closely as possible so as to avoid unnecessary density or hardness.

The most convenient size for the negative from which to make micrographs is, perhaps, 5 by 4, used in a small copying camera; but nothing need be said with regard to appliances beyond that the objective must be one that will give the finest definition and work to focus. An inch

and a-half or two inches is about the best for the purpose. The focussing of the image is best done by moving the negative, unless the exposure of the plate is made at the stage of the microscope, which is really the best way of working.

Although, as just said, an exceedingly fine grain is obtainable with the wet collodion process when employed under the best conditions, a still finer grain, however, can be obtained with the albumen process when it is worked at its best. It is a more troublesome process to work, and the exposures required are very prolonged compared with collodion, and it is doubtful if the extreme fineness secured is, in practice, worth that extra trouble, seeing that all the earliest micrographs, the excellence of which our older readers will well remember, were made by the collodion process. It may, however, be said that those now sold at bazaars in holiday resorts, in trinket form, are by that process, and are certainly very bad, and are not to be compared for a moment with those made some forty or fifty years ago as regards fineness of deposit.

With regard to the working of the albumen process for this kind of work, it will not differ from the usual method. The albumen is prepared and iodised in the usual way, but it may be as well to mention that the iodised collodion employed as the substratum, should be old, yield a clear film, and be quite free from structure. The silver bath should be thoroughly saturated with iodide of silver, and the time of immersion of the plate in it should be short—not more than half to three-quarters of a minute at the time of the year. The developer may be either a solution of gallic acid, or an acidified one of pyrogallie acid, with in either case, a drop or so per ounce of a twenty-grain solution of nitrate of silver added. The developer, whichever is used, is best employed at a temperature of 100 deg. to 110 deg. F. If, when the albumen picture is fixed, it is considered to be too brown or warm in colour, it may be toned in the old gold and hypo combined toning and fixing bath. If that is done it should not be overdone, the pictures dry up considerably darker than they seem while wet.

## THE PHOTOGRAPHY OF COLOURED OBJECTS IN PRINCIPLE AND PRACTICE.

[The following article, which is completed in this issue, is composed of several chapters from a book by Dr. C. E. K. Mees, to be issued under the title of "The Photography of Coloured Objects." Dr. Mees' treatise so well explains matters in the practice of orthochromatic photography that frequently present difficulties, that by permission of his firm we quote from advanced sheets of the book. The full text of the latter we would recommend to the perusal of our readers, for the sake of the chapters on portraiture, landscape, reproduction work, and the tri-colour process, all in relation to the photography of coloured objects. Messrs. Wratten and Wainwright will shortly publish the volume at a nominal figure.—Eds. "B.J."]

### Colour Contrast for Special Purposes.

The type of colour contrast which we have been describing is simply a concession from orthochromatism, in order to enable us to some extent to make up for the failure of monotone rendering when it is necessary to render colour. But there is another case of the photography of colour contrast which is to the technical worker of as great, if not greater, importance, and that is the photography of coloured objects *per se*, in order to obtain the best possible results, generally for reproduction purposes.

**General Principles.**—If a colour is to be rendered as black it must be photographed in its absorption band by light which is of such a wave length that it is completely absorbed by the colour. That colour then appears as black as it can be made.

A useful example is given by a photo-micrographic section stained with eosine. This section is pink; if it is viewed by blue light, owing to the fact that eosine does not absorb blue, it looks comparatively light. By green-blue light of wave-length about 4,800 to 5,200, which is completely absorbed by eosine (see Fig. 15), the section is entirely black, as is shown by Fig. 16, being blocked up in detail; this gives the maximum degree of contrast. Photographing at 5,700 on the border of the absorption band, we get a lessened contrast (Fig. 17) which for this particular section will give us the best result. There is plenty of detail in this section, while at the same time the contrast is sufficient for reproduction purposes. Photographing at 6,400 in the red, and in light which is completely transmitted by the section, the section has no contrast, is very

at, and results are useless (Fig. 18). So that for the maximum contrast we must photograph in the absorption band. Let us take two practical instances:—

(1) Given an engineer's blue print showing white lettering

Fig. 15.

on a blue ground. We require to reproduce it for a line block. This blue print has a strong absorption in the red. If we photograph it through an A screen, the strong red screen used for tricolour photography, or better, through the screen made specially for this work, upon a process pan-

Fig. 16.

chromatic plate which is quite sensitive to this deep red light, when we shall get the maximum contrast which can be obtained, and, as a matter of fact, the blue will be to all intents and purposes an intense black, and there is no difficulty whatever in obtaining our negative.

In photographing typewriting, a green screen must be used, and if there are any red ink corrections the green screen will record these also. If, however, a red screen be used, the typewriting will record satisfactorily, but the red ink will disappear.

Fig. 19

Suppose, to take another example, we have a sheet of typewriting with corrections in red ink. The violet typewriting absorbs the whole of the orange and green, the red ink absorbs only in the green. If we photograph through the green filter of the tricolour set, B, we shall get both the typewriting and the red ink completely black (Fig. 19), and the greatest contrast which can be obtained. If, on the other hand, we photograph through the red A filter, the typewriting will appear plainly

visible, but the red ink will show so little contrast that it can easily be intensified out of existence (Fig. 20), and we can make a reproduction of the sheet showing the typewriting only.

By the application of this principle we can pick out, in fact, any colour from a combination of colours, and in two, three, or four printings obtain a facsimile result. For the application

Fig. 20.

of this principle to photomicrography, in which it is of great importance, see a little booklet which I published some time ago called "The Selection of Plates and Filters for Photomicrography."

(2) The second principle of importance is that where a uniformly coloured thing is to be photographed and the best

Fig. 17.

Fig. 18.

rendering is to be obtained, it must be photographed, not in its absorption band, but in the transmission or reflection region of the colour. That is, by using light of the same colour as that which is reflected by the object, not of that which is absorbed. For instance, in photographing the eosine-stained section we get the greatest contrast by photographing in the absorption region of the stain, but we obtain that contrast at the expense of the loss of detail in the section, and we get the greatest detail in the photograph where we used the red light. Owing, however, to the fact that we must keep contrast against the background in this case, our best final result was a compromise between contrast and detail, obtained by photographing on the border of the absorption band. A very good example, however, of the use of light such as is transmitted by the stain is shown by the Figs. 21 and 22 of a whalebone section, which are reproduced here from the little book on photomicrography. The upper one shows the section photographed for contrast by means of light which is absorbed by it; the lower one shows the same section photographed by the light which it transmits in order to show detail.

The most important instance of this method with which I am acquainted occurs in the photography of furniture, where the results obtained are simply startling to the uninitiated. If a piece of reddish mahogany is photographed on an ordinary

plate no trace of grain is usually visible. The photograph is made by blue light, to which both the red darker portions and the yellow light portions are black; to give an increased expo-

Fig. 21.

sure simply results in the photography of a plentiful crop of normally invisible scratches (Fig. 23). If, however, a panchromatic plate sensitive to the red is used, with a strong

Fig. 23.

yellow screen, the results are entirely different; the scratches disappear and the grain comes up in the most wonderful way; in fact, so startling is the difference that probably many of my readers will think that Fig. 24 herewith is faked, but I

can only assure them that if they try the experiment they will get similar results.

A useful example of this same principle of photography

Fig. 22.

in the coloured light which is reflected from the object is given by the photography of prints for reproduction purposes. A warm sepia carbon print, for instance, if being copied for

Fig. 24.

photographic reproduction represents a most difficult object, the shadows invariably clogging, and the whole scale of contrast becoming greater in spite of any variations of exposure.

development. In the same way, a red silver print when photographed on wet plates for half-tone work is well known as a most difficult subject, requiring usually a large amount of fine etching. These and any other cases of the

same kind can be dealt with very easily by using panchromatic plates with a medium screen. The prints then become as easy to copy as any black-and-white subject.

C. E. KENNETH MEES, D.Sc., F.C.S.

## THE HALIDE CONTENTS OF P.O.P. AND OTHER SILVER IMAGES.

In the "British Journal of Photography" for February 21 of this year there appeared an article by me dealing with the question of the nature of the image on a P.O.P. print. Very soon after the publication of this article an experiment I was then conducting made me suspicious of the conclusion I had come to that the P.O.P. image contained much silver chloride. I printed out a very faint image on a piece of P.O.P., and then, after fixing and washing, found I was able to develop up a yellowish brown image of full strength by immersing the print in a dilute solution of silver nitrate to which a little metol and citric acid had been added. Here I got an image very similar in appearance to that produced by exposing P.O.P. to the light and then fixing it, which image could not contain much, if any, silver chloride. This developed image behaved on development just as the ordinarily produced image on P.O.P. does. I saw at once that I must re-examine the question of the P.O.P. image, for what had made me first accept the views put forward in the above-mentioned article was the difficulty of explaining the action of sulphide solutions on the P.O.P. image unless this image contained a large percentage—at least 20 per cent. or so—of silver chloride. I did not accept the views I expressed last February without examining (as I then thought thoroughly) the fixed P.O.P. image for silver chloride, and, as I then believed, finding it in very sufficient quantity. Much of the silver chloride I then found, however, I now know, produced by the silver as it passed to the solution acting on traces of sodium chloride left over in the paper from the fixing bath. The mass of the silver of the image so small that very small traces of a soluble halide are sufficient to precipitate a considerable portion of it. At the time I was examining the fixed P.O.P. image for silver chloride I was quite aware, of course, of the chance of traces of sodium chloride being left in the prints, and of the result such traces would have, but I thought the washings to which I subjected the prints were ample to eliminate all such therefrom. Moreover, on subjecting bromide prints to the same treatment as plainly fixed P.O.P. prints I found a less halide present in their case. It was this latter fact which made me less careful than I should have been to see to it that the washing of the prints experimented with was thorough and sufficient to eliminate the last traces of soluble halides, for it appeared to me at the time to be practically certain that if any trace of a soluble halide was left in the paper similar results would be given by bromide or gaslight papers and by P.O.P. This, however, is not the case. The explanation of the difference of behaviour of bromide or gaslight and fixed P.O.P. prints containing traces of soluble halides when exposed, as I exposed them, to a solution of ammonium persulphate is as follows:—The action of the ammonium persulphate is a good deal slower on the P.O.P. image than on the bromide or gaslight one, and so more time is given for the soluble halide to diffuse up to the dissolving silver. In the case of a P.O.P. print all the silver chloride is precipitated in the position of the image, but in the case of a bromide print it is precipitated partly in this position and partly elsewhere. While I worked with ammonium persulphate and did not properly wash the prints, I always noticed, on subsequent development, a stain produced behind the image in the paper of bromide prints. I thought at the time that this stain was due to combination having taken place between the paper and the dissolved silver, the concentration being greater here than elsewhere, and owing to the quicker action of the solvent, greater than in the case of a P.O.P. print. I now know that the stain was brought about by traces of halide which I had not properly washed out. Well, I need not go on with this story any longer, but can pass to the description of the proper method of examining a silver image for its halide content and the conclusions which experiments carried out in this way have forced upon me.

The last traces of sodium chloride and bromide left over from the fixing operation are only eliminated by very prolonged washing. In older text books of photography great stress was always laid on washing plates and papers for several hours in running water after fixation. Now, it is the fashion to advise that the final washing should be of less duration—an hour is generally about the time recommended. Of course, much depends on the method as well as the duration of washing, but certainly no matter how satisfactory the method be, an hour is not sufficient whenever any harmful substance has been brought previously into contact with the plate or paper.

In my later experiments, in investigating the halide contents of the images of prints, I worked with quarter-plate prints, and, after fixing, washed these singly in quarter-plate dishes. Water was allowed to run continuously into the dish at the rate of about 2 oz. in 10 seconds, and the prints were turned over every half-hour or so. I found it necessary to continue washing for five hours in order to get rid of all the soluble halide salts. Strictly speaking, of course, it is not possible to wash out all the soluble halides with tap water because this always contains a very small quantity of soluble chlorides, but this amount is so small as to be practically negligible, especially if the bath used for dissolving the silver is made up suitably. When the print has been thoroughly washed it should be immersed in

Ceric sulphate .....	90 grains.
Conc. sulphuric acid .....	150 minims.
Silver nitrate .....	3 to 4 grains.
Water .....	10 ozs.

The object of the addition of the silver nitrate is, in the first place, to get rid of any soluble chloride present as an impurity in the water used in making up the solution or in the other chemicals, and in the second to precipitate any small trace of soluble halide left in the paper in situ, and so prevent it from being precipitated in the position of the image. Ceric sulphate acts rapidly and readily on all silver images. After all the silver has been dissolved out of the image the print is thoroughly washed again in running water, and is then treated with a solution of pure crystalline sodium sulphide or sulphuretted hydrogen. This, by converting the halide content of the image into silver sulphide, renders them visible.

When examined in this way, it is at once apparent that the halide content of the images, both on plainly fixed P.O.P. and on bromide and gaslight papers, is very small—far too small, in my opinion, to account for any of the properties of these images. In fact, in the case of bromide paper, the halide content is almost invisible. No matter for however long I have washed a print or negative I have never failed to find some halide content in the image. I am therefore as convinced as before of the correctness of the "lake" theory, but I now regard the fact that the silver contains silver halide dissolved in it as one that is certainly interesting in itself, but not capable of explaining many of the phenomena which it has been alleged by myself and others to explain. Before going on to consider these phenomena, I must here add that I have lately several times repeated the analysis of the image on plainly fixed Barnet P.O.P., and find that owing to insufficient washing I greatly over-estimated the percentage of silver chloride contained therein. My later results show the halide content to be very small. My experiments were not elaborate enough to enable me accurately to determine the actual percentage of this halide content, so it would only be misleading to give the exact results. Let us now consider some silver images and see how far their properties can be explained by reference to their halide contents. It is well known that if the black silver image of an ordinary negative or bromide print be bleached and then redeveloped with a suitable developer an image showing marked increase in "body" results. If the halide content of the image on a negative

before and after redevelopment be examined by the method above described—and this can be done by cutting the negative in half and redeveloping one half—it will be found that the increase in halide content is very small. I am myself by no means certain that any increase really occurs at all, if the redevelopment is carried out to completion. It may well be that some bleached images can only be redeveloped to yield a lake containing a good deal more silver halide than the original image, but I can only say that, if this is so, I have not met with them. I find no difficulty in redeveloping an image bleached in a solution of iodine and potassium iodide to one containing very little silver iodide indeed, provided a powerful redeveloper is used and sufficient time allowed for its action. In every case of redeveloped image seems to me to be a molecular one. The results of density in the image. I have never found, however, that a second redevelopment gave further density. The only possible explanation of the increase of covering-power possessed by the redeveloped image seems to me to be a molecular one. The results of the experiments I have lately carried out appear to me to put aside altogether an explanation depending on an increase of the halide contents of the image. What the exact molecular change is which takes place nobody, of course, can say, but I may perhaps be not going too far in suggesting that if the spaces between the ultimate molecules forming the particles of which the image consists are increased an increase in size of these particles would occur. An increase in the size of the particles of the image does occur in redevelopment, and it is this increase in size of the particles which gives to the image its increased "body."

I, of course, admit that this theory does not give such a satisfactory explanation of the result of sulphuration as that depending on the increase of halide content, but we must abide by facts. If a bromide print is bleached and redeveloped, and then bleached again and sulphuretted, the silver sulphide formed has exactly the same covering power as that formed by bleaching and sulphuretting the original image. We must here assume that the intermolecular spaces are not so variable in extent in the case of silver sulphide as they are in the case of metallic silver.

Another fact about redeveloped images is that very often, but not always, they are acted upon quite readily up to a certain point by a solution of a soluble sulphide, and this phenomenon we must, I think, now ascribe to some molecular change rendering the image more easily open to attack.

Before leaving the subject of bromide and similar papers, I must mention a very interesting fact, and one which I personally think is of considerable practical importance, viz., the difference in colour produced by redeveloping from a chloride bleached image as opposed to a bromide or iodide bleached one.

Images redeveloped from a chloride bleached image by a redeveloper containing no potassium or other soluble bromide possess a beautiful blue-black colour. A similarly coloured image is also produced by properly carried out primary development of gelatino-chloride or gas-light papers, and those having certain chloro-bromide emulsions spread upon them. It may possibly be the fact that the silver chloride, although in extremely small quantity, affects the molecular state of the silver in some particular, but it seems more likely that the special molecular state of the metal on which the colour depends is regulated by the chemical and physical composition of the substance from which it has been developed. It is an interesting fact that an image developed out by primary development of a blue-black tone yields on sulphuration one of a rather yellowish brown. To come to the case of P.O.P., we must ascribe the fact that the image is so easily attacked by sulphide solutions and also the loss of density on sulphuration to causes depending on the molecular structure of the silver, for no other explanation seems available. If a P.O.P. print be plainly fixed and washed and then exposed to an atmosphere containing much sulphuretted hydrogen or else to a weak solution of a soluble sulphide, the image changes colour, passing from brown through red and purple to a dirty bluish brown, and finally becoming very faint in density. These changes in colour and density would appear to be almost certainly caused by the formation of a film of silver sulphide on the surface of the silver particles, which gradually gets thicker and thicker until at last all the silver is converted into silver sulphide. Now, I don't think it can be denied that the "lake" theory I previously advanced offered a more satisfactory explanation of the colour effects and the change of covering-power.

Reddish chloride-sulphide lakes are known, and the change of density seems very great for a purely molecular explanation. When bromide print which has had a "correct" exposure and full development is sulphuretted the covering power of the sulphide image seems to be quite equal to that of the original one, but this is the case where it is so. As an explanation depending on the halide content of the image is no longer available, we are forced to the conclusion that the molecular state of the silver sulphide of a photographic image is often very different from that of the silver from which it is derived.

It is curious that a film of silver sulphide of a certain thickness produces a red colour, but so it seems to be.

I believe that the red constituent of the tone of a finished P.O.P. print is always caused by sulphuration, and never by the deposition of gold. It is, of course, quite possible that a film of gold in a certain molecular state might give almost any colour to the image, but I have never been able to obtain any evidence of any effect caused certainly by the sole action of gold which gives any "warmth" to the tone of the image.

It is commonly stated that the permanence of P.O.P. prints depends on the kind of toning which has taken place. It is said that those prints which have been toned with gold are permanent, and those which have been "sulphur toned" are likely soon to fade. I think this is a totally wrong view of the matter. I don't believe there is any such thing as "sulphur toning," if by this is meant deposition of sulphur on the image. I believe, as stated above, that a film of silver sulphide is formed on the surface of the silver of the image, and that the toned image consists essentially of silver and silver sulphide. Generally, where gold is contained, as it practically always is, in the toning bath the image consists of a certain small amount of blue metallic gold as well, which causes the tone to verge away from red towards purple. We know also that certain gold solutions react with silver sulphide, and no doubt some of the products—probably aurous sulphide—of this reaction is also present under certain circumstances.

Silver sulphide is an extremely stable compound, and its presence cannot have any injurious effect on the permanence of the image.

I believe there are two causes of want of permanence in P.O.P. prints: (1) "Retained" silver or lead, (2) traces of unstable sulphur compounds left in the print through insufficient washing. I discussed the question of "retained" silver and lead in my article of February 21, and I need not again go into it.

When the image of a P.O.P. print fades the result obtained is exactly the same as when a solution of a soluble sulphide has been allowed to act upon it beyond the time necessary for reaching the purple-coloured stage. The conclusion seems irresistible that the fading is due to sulphuration.

Prints which have been toned in a "combined" bath have long been suspected, and undoubtedly a great quantity of such prints have possessed a very short life. I believe that this has come about because the "combined" bath is so often improperly used, and not because its use is necessarily dangerous. A "combined" bath must be made up properly and properly used, and the print must be washed very carefully after toning. But somebody will very likely say: "I have washed prints toned by the 'combined' method as by the 'separate' one in an exactly similar manner and have found that while those toned in the 'combined' bath did not last as long as the others have done so." Yes, undoubtedly many have had this experience. The reason probably is—leaving aside those who, by using a badly made-up bath or misusing a good one, have made the acquaintance of "retained" silver or lead—that neither lot of prints were properly washed, but that in the case of those toned and fixed separately the substances left in were not nearly so harmful as in the case of the others.

I ascribe the early fading of many P.O.P. prints merely to the fact that substances were left in the paper and gelatine film of an unstable nature, which decomposed and gave off sulphuretted hydrogen and so sulphuretted the image. But some one will want to know why bromide prints toned in the hypo-alum bath are so stable, for "surely," he will say, "you don't imagine that all such have a long and careful washing given to them after toning." No, most certainly I don't. However, in this case the liberated hydrogen sulphide will do no harm, for it cannot act on a complete

phuretted image. The case of negatives or bromide prints fixed in acid fixing bath is also interesting in this connection. I don't imagine that the residuum of the acid fixing bath is nearly so unstable as that of the much more strongly acid "combined" toning solution, still I should certainly say that it is more unstable than that of a neutral solution. The power of resistance to the action of sulphuretted hydrogen possessed normally by black silver images is very considerable, so that I can quite understand how the acid fixing bath proved itself innocuous.

If late there has been a reappearance of baths for toning P.O.P. prints from which gold is absent. I don't think there is any objection to the use of such provided they are made up properly and properly used. An ordinary hypo-alum bath, to which a little lead is added—not more than half a grain to the ounce—has been found to be apparently quite good; so, too, is a very dilute solution of pure crystalline sodium sulphide made distinctly alkaline by the addition of caustic soda solution, provided that silver can be obtained showing complete absence after fixing of combination between the soluble silver and the gelatine, but this, as stated in my previous article, I personally doubt.

Those who wish to use any toning bath containing unstable sulphur compounds must see to it that they not only employ a good bath and use it properly, but they must be careful to wash their prints in an efficient manner—i.e., the prints must be got to move properly in the washer—and they must continue this washing for five or six hours. While I firmly believe that there is nothing to take the place of really thorough washing, it would be interesting to know what effect treatment with an alkaline solution subsequent to toning would have on the permanence of prints toned in a "combined" bath and rejected afterwards to a moderately long washing. It certainly seems probable that where lead is absent from the toning bath a beneficial effect ought to be produced, and even where lead is present this effect should still show itself. I am at present conducting experiments on this point, and naturally some considerable time must elapse before any conclusions can be drawn.

In stating my belief that silver sulphide is present in the toned image of P.O.P. I am quite aware of the fact that some hold that a brown image of a sulphuretted bromide print consists of a gelatino-sulphide of silver. I do not, however, agree with this view. Those who uphold it point to the facts that (1) the colour of the image is brown and not black; (2) when the film containing the image is dissolved in hot water a brown solution-like liquid is obtained.

These facts do not seem to me to be worth much. In the first place, brown silver sulphide can be easily obtained. If we produce a film of silver sulphide, or get the substance in a fine state of suspension, we notice that it is brown in colour. The following experiments show this clearly enough:—

A) Put a drop of the solution of a soluble sulphide on a coin or other article of silver and a thin brown film of silver sulphide results.

B) Dissolve 1 grain of silver nitrate in 40 ozs. of water and add a few drops of a 20 per cent. solution of sodium sulphide and a brown suspension, due to silver sulphide in suspension, will result.

It is, of course, very well known that sulphides very often exhibit the phenomenon of suspension. I hold that the brown solution-like liquid that is formed by dissolving the film from off a sulphuretted bromide print is merely an emulsion of silver sulphide. Gelatine, as is known by everybody, has the power of holding in fine suspension or "emulsifying" various solids. It does not seem to me to be at all curious that a solution of gelatine should hold in very fine suspension a solid which even water can to a certain degree so hold. Much for the arguments of the gelatino-sulphide theorists. Now I ask them a question. How do they account for the fact that if a compound is formed no spreading of the image occurs? The fact that when a bromide print is sulphuretted a perfectly sharp image, showing no signs of "running," is formed in the same place as the original silver one, seems to me to upset altogether the compound view and to show that the image consists of pure silver sulphide. If, however, it should turn out to be the fact that a combination between gelatine and silver sulphide does occur in the sulphide toning of bromide prints, then it is very likely that such takes place in the case of P.O.P.

R. E. BLAKE SMITH.

## BIRMINGHAM PHOTOGRAPHIC SOCIETY.

### OPENING OF NEW ROOMS.

THE rooms recently acquired by the B.P.S. in Exchange Buildings, New Street, were inaugurated by the Lord Mayor on the 6th inst. At an early period of its existence the society held its exhibitions on the same premises, but for the last seven years the members have assembled in Norwich Union Chambers. The new home of the society is more convenient in many ways. There is a meeting-room 46ft. by 21ft., with lantern screen, as well as a reading-room and dark-room. In view of the important departure made by the society it may be interesting to review briefly its history. The present society was founded in 1884, but Mr. Harold Baker, in a paper read some years ago, traced the development of the photographic art in Birmingham as far back as 1790, when experiments were made with sun pictures by Boulton and Watt at Soho. One of the earliest Daguerreotypes made in this country was the work of the late Mr. Geo. Shaw, and Dr. Hill Norris, who became the first president of the society, patented a collodion dry plate as early as 1855. The first society was founded in Birmingham in 1856, with Mr. W. B. Osborne as hon. sec. One of its objects was to build a gallery for the exhibition of members' work, but before this was realised a heavy deficit on an exhibition brought the society to an untimely end. The society lived long enough, however, to develop considerably the art of photography in Birmingham, and one of its achievements was the raising of a fund to induce Pouncey to reveal the secret of his carbon process. Mr. W. Willis, a member of the society, was the inventor of the platinotype, and another Birmingham man, Mr. Alex. Parkes, made a substance which he called Parkesine, and which is now largely used as a basis for celluloid films. The present society began in a very modest way in a room at the Technical School. In 1887 the question of photo survey work was introduced by Mr. W. Jerome Harrison, and taken up by Sir J. B. Stone, who had been privately engaged in securing records for many years. The National Photographic Record Association was formed, and was instrumental in supplying the British Museum with valuable records of old customs and contemporary events. After holding several successful exhibitions in the Exchange Rooms, the society received artistic recognition by being invited to hold their exhibition at the Royal Society of Artists. Photographers from all parts of the world now send pictures to this exhibition. The society will continue to hold the annual open show in the rooms of the Royal Society, but it is intended to hold periodical exhibitions of members' work in the new rooms. The first of these minor exhibitions was held on the opening night, when some fine examples of members' work were shown. There was also a lantern display, the most striking feature being some fine Autochrome slides by Messrs. Baynton, Holder, Leeson, and Partridge. The programme also included some musical items.

Mr. Harold Holcroft (president) was in the chair, and there was an overflowing attendance. The president pointed out the advantages which members would have in the new rooms, and expressed the hope that they would use them in the daytime as well as evening. They intended to develop the social side, and it was possible that the subscription might be reduced in order to increase the membership. The society had a good reputation for artistic work, but its membership was not so large as it should be, considering the size of the city. In conclusion, he welcomed the Lord Mayor as a brother photographer, a former member of the society, and as a future subscriber.

The Lord Mayor congratulated the society on having moved into rooms so centrally situated and so well adapted for their purpose. He thought everyone should have some hobby in which he could take an active interest, and because photography fulfilled that requirement he had come to give the society the civic blessing. One could not look round those rooms without seeing that the artistic element was very much to the fore in the society, and he would rather have such photographs hung on his walls than an indifferent oil painting. He took a camera with him on his holidays and illustrated his diary with photographs, which in after years recalled pleasant memories as he turned the pages. There was also pleasure to be derived from the freemasonry which existed among photographers wherever they went. In conclusion, he wished the society all success, and would be only too pleased to do all he could to further its objects.

Dr. Hall Edwards, in proposing a vote of thanks, said photography

deserved a civic blessing, because it enabled the public press to give people a more accurate account of scenes and events than could be given in words. The pictorial side of photography had been developed to its limit, but its educational and scientific uses remained to be developed. Already the lecturer had to provide himself with slides in order to get a hearing, and the time would come when the same consideration would be shown to children in schools. He was glad to see that the scientific section of photographic exhibitions, which was formerly the darkest corner and used as a cloak-room, was coming into greater prominence.

## Exhibitions.

### SOUTHAMPTON CAMERA CLUB.

THE first of the triumvirate of southern exhibitions is now open in the Philharmonic Hall, Southampton, where, as usual, a strong collection of work has been got together. Hove and Portsmouth follow in the order named. A glance round the exhibition now under consideration reveals the fact that fewer frames than usual are on show, but the same glance will also show that the usual high standard of excellence is well maintained, even if there is no actual advance. Indeed, the standard of the work submitted this year is so high that the hanging committee have been able to exhibit every frame sent in, and it is not too much to say that there is no picture on the walls that can be considered bad. Three hundred and twenty-four frames in all are shown, composed as follows:—One hundred and thirty-two by members of the Southampton Camera Club, one hundred and forty-eight in the open competitive class, and the balance of forty-four represents an interesting loan collection.

Taking the members' classes first, we find that Miss E. Alder shows an interesting study in Hereford Crypt; E. E. Butler shows a good view of the "Wirtschaft Wasserfall," Switzerland; and O. P. Butler's one-frame "Hamble Marshes" is a good rendering of the subject, although we consider it somewhat low in tone; his slides, however, are better in this respect. C. H. Burr is best in "A Wee Burn," whilst A. D. R. Bacchus shows some fine technical work in "Pictures from Birdland," and his slides, also of technical subjects (snails, to be exact), are very nice indeed. Cecil Daw shows but one frame this year, and although it is a pleasing picture it is by no means up to his usual high standard. R. G. Vaughton Dymock shows sixteen frames, the best of which we consider to be "Evening in the Teign Estuary," with "Ships that Pass in the Night" a good second. H. Essex is one of the club's strongest workers, and "Rainy Day in a London Suburb" enhances his reputation, being one of the finest renderings of a wet pavement that we have seen. "Sunshine on the Old West Gate" is a little behind the other in excellence, and "Passion Flowers," a delicate floral study, shows the worker's versatility to advantage. Mr. Essex also takes an award for a set of excellent landscape slides. Mrs. Alan Francis exhibits three frames, of which "A Five Foot Jump" is undoubtedly the best. A. Gibbings has four frames, of which the best is "Evening," the sky of this picture being particularly well rendered, but the water is monotonous and the shadows somewhat heavy. The Rev. John Heath is best represented by "Oliver Goldsmith's Resting-place—the Temple," and this picture earns him an hon. mention, the sunshine and atmosphere being particularly well controlled. A. E. Henley shows ten frames, but it is evident that his opportunities for pictorial work in the past year have been fewer than usual. His best is a "Sunlit Lattice," but this picture shows signs of halation. "In a Tudor Room" is better in this respect, but the inclusion of the very modern figure is unfortunate, and green is not the best colour in which to have rendered such a subject. "The Pass of Llanberis," by the same worker, is a broad rendering of a somewhat hackneyed subject. C. D. Kay exhibits some very fine professional work "Not for Competition," which shows to splendid advantage the capabilities of the electric arc lamp for portraiture. His picture, "A Temple Half as Old as Time," is a good rendering of sunlight on an old stone muredo. W. R. Kay shows six frames, and takes an award and two mentions, and also an award for slides. S. G. Kimber, who is, of course, the pictorial leader of the club, as well as its mainspring in business

matters, is strongly represented, and the best of his frames, "A Portal," is certainly worthy to compare with his past successes, both in technical quality and pictorial excellence. "The Crypt, Hereford Cathedral," is not far behind, and "Sunny Lassie" finds general favour with all visitors at the show. We cannot help thinking, however, that it is perhaps rather heavy. The best picture exhibited in the name of H. W. Miles is "Green Grow the Rushes," and "Test at Greatbridge" will prove of more than passing interest. E. H. Plumptre's best exhibit is "Northam Bridge." The atmosphere is very fine, but the whole picture is too low in tone and an unpleasant colour; the framing also, we think, might have been more carefully done. R. E. Parson receives a well-merited hon. mention for "In Lowestoft Harbour," which is undoubtedly the best of his four frames. The picture somewhat lacks balance, but that is the only fault we can find with it. His slides are somewhat unequal in quality, but the best are very good indeed, and for these he has also received an hon. mention. W. P. Purvis shows "A Corner of Romsey Abbey" and "A River Landscape," but the architectural study is easily the better. H. J. S. Quilter takes an award for "Play of Sunlight," and would have received another in the same class for "Autumn," but the rules of the exhibition only allow him to take one. The former picture is a new rendering of that well-worn subject, sunlight on whitewash, and Mr. Quilter is to be congratulated on obtaining a satisfactory picture of this nature on his own. A. Rumsey receives an award for "Jews' Quarter, Rome," but equally good we consider is "A Corner in an Old Roman Garden." Mrs. Swainson receives a mention for "Spring Flowers," a delicate floral study. Another good picture by the same worker is "The Turn of the Plough," but the white inner mount is almost fatal to the tones of the print. Mrs. Tugwell also receives a mention for "April with its Changing Light," a bold rendering of a tree trunk against a strongly lit April sky. Guy C. Vachell is the strongest competitor in the club classes this year, and we cannot say but that he has earned the many awards he has received. Seventeen frames represent Mr. Vachell's work for the year, but his awards prove that quality, as well as quantity, has been the object before him. "Evening on the River Mole" we consider his best picture; "The Imposition" has been preferred by the judge. "Portrait of Colonel Heathcote" also receives an award (debarred), and "Study of a Girl's Head" is a particularly pleasing piece of work. In addition to the several awards already mentioned, Mr. Vachell receives the champion club award for the best collective exhibit in the members' classes. Smith Whiting is easily the strongest natural history worker in the club, and this year Mr. Whiting's five frames earn an award and three mentions. "A Story in Three Chapters" represents a pied wagtail feeding a young cuckoo whilst standing on his shoulders, and is of far more than mere photographic interest. This has been the judge's favourite, but "The Gannet" is perhaps quite as strong, and one of the best renderings of the subject that we have seen. C. H. Witt has four frames, of which the best is undoubtedly "On Southampton Common, April 26." F. Watson has a dog study in "Lionel," and Dr. Milner White shows three pictures, "Not for Competition." "Bayeux Cathedral" would have been the best of these if judicious use had been made of the trimming knife. As it is, we prefer "A Stormy Sunset." Dr. Milner White is one of the club's best friends, and members and public alike are always glad to see his interesting work.

The open competitive classes are exceptionally strong this year, but space will only permit us to mention a few of the most outstanding pictures. There are many others, however, with almost equal claims to consideration. A few of the exhibitors of past years are not represented on the walls. Some are new to Southampton, but the bulk of the work is by those who have exhibited year by year, and it is gratifying to find them showing this appreciation of the treatment they have received at other times.

Miss Gertrude Aitchison is best represented by "A Flemish Canal." Herbert Baird is especially good in "Around the Camp Fire," and Mrs. G. A. Barton, to whom the judge has made two awards as strong as ever—"Summer," in particular, strikes us as a most pleasing production. E. W. G. Burder shows good colour work, and receives a well-merited award for "Oranges and Bananas," and "Matter of Opinion" earns a similar honour for Bertram C. E. F. H. and Miss Crouch exhibit some good work this year, and Dan Dunlop follows up his previous successes at Southampton

taking an award with "Edinburgh Castle from Greyfriars." This we consider one of the best things in the class, and certainly the best rendering of this subject we have yet seen. Miss E. M. Gladstone shows distinct promise in "Three Score Years and Ten," and C. H. Hewitt, although he has failed to catch the judge's eye this year, has a particularly fine rendering of a strongly lit face in "The Mirror." The control of light and shade in the last-named picture is masterly, but we cannot help thinking that there should be more suggestion of the mirror. Oscar Hardee scores with "Isabella en Jan Wilden," perhaps actually the finest picture in the show—though "The Harvest that is to be" is but little behind it in excellence—and Heinrich Hinz takes an award and an hon. mention for fine, straightforward photography. Aubrey Harris is well to the fore with "After the Ball," and A. F. Hirschfeld's work is excellent, especially "The thoughts of youth are long, long thoughts," which, like the previous picture, receives a "mention." Ellis Kelsey and V. E. Morris are responsible for some of the best slides in the show, and H. W. W. McAnally, in "An Italian Hillside," is well represented. The Autochrome slides by Captain W. Stomm and P. D. Prior show to the full the possibilities of Messrs. Lumière's plates in careful hands.

Mrs. Ambrose Ralli's best picture is "Algeciras," the composition being pleasing and the general effect bright and sunny, as one would expect such a subject to be. Miss Dendy Sadler shows some delicate work; and another lady, Miss Hilda Stevenson, though not even quite at her best, has a fine oil print in No. 237, "A Portrait." A. Taylor receives an award for his series of natural history prints illustrating "The Life History of the Tawny Owl," although the "Domestic Habits of the Song Thrush," another series of absorbing interest, is practically as good. Miss F. C. Vandamm has a powerful figure study in "The Monk," and other exhibitors of fine work are Miss Agnes B. Warburg, A. W. Ward, and B. C. Wickham.

The most interesting work in the whole exhibition is undoubtedly the fine collection of loan exhibits, and this includes the work of most of the strongest men in the British School. The collection has been carefully arranged in panels, and consequently is shown off to the greatest advantage. The first panel includes four examples of Mr. Arthur Marshall's coloured oils. Chas. Job follows with four of his beautiful South Country landscapes, and in the next panel Alex. Keighley shows four of his strongest pictures. John H. Gear has three small but attractive prints, whilst Mrs. G. A. Barton and H. Blake show four and two respectively. F. J. Mortimer, W. Rooke, Harold Baker, Frederick H. Evans, and J. M. Whitehead each represented by four of their best works, whilst Archibald McPherson and Reginald Craigie are less prominent only in the number of their exhibits.

Thus it will be seen that a very fine collection of pictorial work on show at Southampton, and we can only hope that the financial results and the interest taken in the exhibition by the general public will prove equally satisfactory, and so encourage the committee to fresh efforts in the future.

In conclusion, it may be said that Mr. Arthur Marshall, A.R.I.B.A., Nottingham, has given general satisfaction to all concerned in the capacity of judge; and though his task must have been a difficult one, his efforts have but helped to enhance the esteem in which he has long been held by photographers of Southampton and neighbourhood.

Another feature at the Philharmonic Hall this week is Martin's photographic Stall, where there is a large display of apparatus and other items of interest to a photographic public. Recitals are given daily at 3 and 7.30 upon the Electrical Auxeto Gramophone, with records by Tetrizzini, Melba, Caruso, etc., and an excellent refreshment stall has been arranged by the proprietors of the Bungalow Café.

CAMBRIDGE AND DISTRICT PHOTOGRAPHIC CLUB.—The fourth annual exhibition will be held in the Guildhall from November 11 to 14, inclusive. There will be awards of specially designed bronze plaques for the open classes, with certificates for those exhibitors obtaining a mention, and a silver plaque for the best picture sent in. Entry forms are now ready, and may be obtained, together with full particulars as to fees, etc., from the hon. sec., Mr. T. J. Sowdon, Sunny Side, Guest Road, Cambridge.

## FORTHCOMING EXHIBITIONS.

- September 11 to October 24.—Photographic Salon. Sec., Reginald Craigie, 5A, Pall Mall East, London, S.W.  
 September 17 to October 24.—Royal Photographic Society. Sec., J. McIntosh, 66, Russell Square, London, W.C.  
 October 13 to 17.—Southampton Camera Club. Hon Sec., S. G. Kimber, Oakdene, Highfield, Southampton.  
 October 14 to 17.—Rotherham Photographic Society. Sec., H. C. Hemmingway, Tooker Road, Rotherham.  
 October 22 to 26.—Hove Camera Club. Sec., W. Chater Lea, Cransley Lodge, Dyke Road Avenue, Brighton.  
 October 27 to 31.—Heaton and District Camera Club. Secretary, George C. Urwin, 24, Tenth Avenue, Heaton, Newcastle-on-Tyne.  
 October 28 to 29.—Watford Camera Club. Entries close October 22. Sec., W. Branch, 100, High Street, Watford.  
 November 2 to 11.—Portsmouth Camera Club. Entries close October 24. Sec., F. J. Lawton, 20, Clarence Square, Gosport.  
 November 4 to 7.—Hackney Photographic Society. Secretary, Walter Selfe, 70, Paragon Road, Hackney, N.E.  
 November 11 to 14.—Cambridge and District Photographic Club. Entries close October 29. Sec., T. J. Sowdon, Sunny Side, Guest Road, Cambridge.  
 November 20.—Redhill and District Camera Club. Entries close November 7. Sec., J. Paterson, Ness House, Redhill.  
 November 23 to 26.—Lancaster Photographic Society. Sec., J. Holt, 11, Fern Bank, Lancaster.  
 December, 1908, to January, 1909.—Kiew International Photographic. Sec., S. T. Horovitz, Technical Society, Kreshtchatik, 10, Kiew, Russia.

1909.

- January 6 to 27.—Northern Photographic (Manchester). Entries close December 11, 1908. Sec., S. L. Coulthurst, Broad Oak Road, Worsley, Manchester.  
 February 13 to March 13.—South London Photographic Society. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been received between September 28 and October 3:—

- DEVELOPING.—No. 20,396. Improved method of and apparatus for developing exposed photographic plates and films. Felix Trüstedt, Johannes Wegener and Ulrich Wegener, 6, Lord Street, Liverpool.  
 LENSES.—No. 20,415. Improvements in telephoto lenses. Owen Edleston Wheeler, "Strathmore," Prince's Road, Weybridge.  
 SCREEN-PLATES.—No. 20,593. Improvements relating to screen-plates for colour photography. Ilford, Ltd., and Rowland Samuel Potter, 8, Quality Court, Chancery Lane, London.  
 DEVELOPMENT.—No. 20,803. Apparatus for determining the relative times of development of photographic plates or films for different temperatures. Alfred Watkins, Birkbeck Bank Chambers, Southampton Buildings, London.  
 COLOUR SCREENS.—No. 20,909. Improvements in and relating to the method of making polychrome screens for colour photography. Charles Louis Adrien Brasseur, 18, Southampton Buildings, London.

## COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

FLASHLIGHT.—No. 10,440, 1908. The invention consists of an improved form of flashlight apparatus in which a shallow tray is carried by a vertical plate. A barrel is attached to the vertical plate, a spring-pressed piston fitting within the barrel. There are means for raising the piston when required. There is a groove

around the piston and a spring-pressed pivoted trigger lever the nose of which can enter the groove and retain the piston in its raised position, which, when it is required to impart a blow to the striker, can be released from the piston by pressure of the thumb of the operator or by pneumatic pressure on its lower end. James Patrick O'Hea, 133, Rushey Green, Catford, London, S.E.

**PRINTING FRAME.**—No. 10,421, 1908. The invention has for its object a photographic printing frame which will print from a number of negatives all at once, and enable all the prints to be examined by the removal of a single backing. It consists of a frame with two, four, or more compartments arranged in pairs, a clip or flap at one side of each compartment, to retain the negative and the paper in each compartment, by one edge, and a single removable backing to cover the major portion of all the prints and rest on the edges of the flaps, so that by lifting the single backing, all the prints will be disclosed for inspection during the operation of printing. Alfred White, 15, Hillside Road, Wallasey, Chester.

**LADDER CAMERA STAND.**—No. 8,314, 1908. The invention consists of a ladder, or pair of steps which is self-supporting, and folds up when out of use, the camera being affixed to a vertical adjustable pillar mounted on the ladder. Wilfred Asa Fessenden, 240, 1st Street, Newaygo, Mich., U.S.A.

**TELEPHONIC TRANSMISSION OF PHOTOGRAPHS.**—The invention consists in obtaining a photographic record from an acetylene or gas light of variable intensity in unison with sound obtained by means of a gas-box with a vibratory side, actuated either directly or electrically, and a slot behind which is the moving sensitive film.

If a shallow gas chamber be fitted on an open side with a vibratory diaphragm capable of motion in unison with sound the pressure of the gas in such chamber is varied in unison with the sound affecting the diaphragm, and a jet of light supplied by such gas varies in intensity with the pressure of same in unison with the sound.

To obtain this result it is necessary that the pressure of the gas at the inlet to the chamber be greater than the pressure of the gas in the chamber, that is, the opening or inlet to such chamber be smaller than the outlet of the jet, compatible always with a suitable-sized flame; the pressure to exceed as little as possible the atmospheric pressure. The chamber is made shallow to make the gas capacity as small as possible so that the vibrations of the diaphragm may cause the greatest amount of varying pressure of gas in the gas chamber.

The action is as follows:—When the diaphragm is compressed, the pressure of the gas in the gas cavity is increased, and the flame at the outlet jet gives out correspondingly more light. When, however, the diaphragm is in the opposite position the pressure of the gas in the cavity is decreased and the flame loses some of its brightness.

The gas used is an illuminating one, such as coal gas or acetylene gas. When the varying light is allowed to fall on a selenium cell in circuit with a battery, a varying electric current is obtained in unison with the sound causing the variations of light, and if a telephone receiver be placed in the circuit, with or without an induction coil, the sound is reproduced. If an induction coil is used, all effect on the receiver of any continuous current through the selenium cell is obliterated, and therefore the sound obtained is of a clearer nature; but it must be understood that as the voltage of the electric current necessary to pass through a selenium cell, when illuminated, must be light, such induction coil should be made in accordance with such pressure and with a secondary coil suitable for the resistance of the telephone receiver to be used.

For permanently recording the variations of light, the phonograph may be photographed by allowing it to fall on a slot or opening behind which a sensitive photographic film is passing at a suitable speed. When the exposed film is developed, a continuous band of silver deposit is obtained, but of varying density according to the variation of the light.

The light may be used direct or passed through a condenser or focussed by means of a lens on the opening. A negative is thus obtained from which a positive is made.

On passing the positive before a steady light placed behind a similar slot or opening to that originally used, variations in the steady light are obtained exactly similar to the variations of the original light, and if this light be allowed to fall on a selenium cell connected with a battery, and telephone receiver, with or without an induction coil, the sounds which caused the original variation of the

light are reproduced. Josiah Frederick Child, "Clovell," 258, Rosendale Road, Herne Hill.

**THREE-COLOUR SCREEN-PLATES.**—No. 3,252, 1908. The invention relates to three-colour screens for colour photography and to an improved process for making, by which the coloured gelatine is reduced to an extremely fine granular state of equal sized grains advantage being taken of the great transparency of gelatine and the property it possesses when desiccated of expanding by the absorption of atmospheric or other moisture. A supporting sheet of transparent celluloid is covered with an even layer of dried transparent grains of gelatine in the three primary colours of the spectrum, the grains being arranged in close contact with each other. After being arranged on the sheet of celluloid the gelatine grains undergo expansion by absorption of moisture from the air under preferably normal atmospheric conditions, or expansion may be attained by the application of a solution of gelatine, then dried and when in such state the grains are forced preferably by rolling pressure into the surface of the celluloid sheet and afterwards coated with celluloid or other varnish, and when dry are again rolled, preferably under slight heat, and if desired may be used on a glass support also. The improved process is as follows:—

1. In dyeing, three separate portions of gelatine (preferably gelatin sheet) in the three principal colours of the spectrum—orange-red, green, and violet.

2. Soaking the dyed and dried gelatine in formaldehyde 15 per cent. solution, after which it is again allowed to dry.

3. The formalysed gelatine is then immersed in water and allowed to expand to its fullest extent, after which it is removed and the external adherent water shaken off. In this state the gelatine is in an extremely brittle condition, and can readily be reduced to a fine granular state by means of the ordinary grinding mill. Should the gelatine be allowed to lose much of the absorbed water during grinding it will regain its natural toughness, and cannot be reduced unless water is added in sufficient quantity to expand the gelatin again.

The finer grinding is most effective when conducted under temperature of about 200 deg. Fahr., when the powder may be allowed to gradually become dry, and the grinding continued until that condition.

The gelatine powder thus obtained is in grains of various sizes. The means employed to separate the grains into various grades of fineness—each grade being in grains of approximately equal size—is a process of elutriation.

The elutriation is done in petroleum spirit of about 700 sp. g., but any other suitable spirit (not absurd by gelatin may be employed. By this process coloured gelatine grains may be selected in batches of equal sized grains, from, say, 1-500 to 1-3000 of an inch in diameter, or plain undyed formalysed gelatin may be reduced to a granular state and then separated into various grades of fineness, after which batches may be dyed in the three primary colours, but the former method is preferable, as by greater transparency of the grains is obtainable.

Three dried batches of coloured gelatine grains thus obtained—orange-red, green, violet, of a size most suitable—are then intimately mixed in such proportions that by reflected white light the mass of combined colours presents the appearance of a neutral grey tint.

To prepare the screen, a sheet of transparent celluloid is thinly and evenly coated on one side with a solution of celluloid and resinous gum, which will remain in a tacky condition during the time necessary to form the screen.

The mixture of coloured gelatine grains, made perfectly dry at a temperature of 212 deg. Fahr., may now be applied (in a desiccator) to the tacky surface of the celluloid sheet by a suitable means, so that the grains are evenly distributed in close contact with each other over the surface in one even layer.

If the screen thus far formed, be now removed to a room under normal atmospheric conditions, each coloured grain will slightly expand by the absorption of the moisture present in the air, and will interlock with its neighbours. After the proper expansion, with the grains the screen is passed under pressure between polished metal rolls, which forces the grains into the surface of the celluloid and fixes their position. The screen may now be coated with celluloid or other varnish, and, when dry, again passed through

rollers. John Bamber, 56, Lansdowne Road, South Lambeth, London, S.E.

**DEVELOPING TANKS.**—No. 1,329. 1908. According to this invention a rack is provided having perforated ends adapted to support a number of plates on edge and out of contact with each other. The rack is used in conjunction with a fluid-tight receptacle or tank of greater depth than the corresponding dimension of the rack, within which the latter fits, and is adapted to slide in two directions, the openings through which the plates have been inserted being closed by a wall of the tank. The latter is filled with solution to a depth sufficient to cover the plates, and by reversing it at intervals, end for end, the rack is also inverted, the liquid flowing freely throughout its length by reason of the perforated ends of a special rack, and also forming a buffer to prevent the effects of a too severe impact of the rack against that wall of the tank towards which it is travelling. Further, as the usual rectangular form of a plate makes it convenient to construct both the rack and tank of similar shape, a suitable device, in no way interfering with the foregoing manipulations, is provided for effecting the fluid-tight engagement of the cover by a rectilinear rather than a rotary movement relatively to the receptacle. Kodak, Ltd., 57-61, Clerkenwell Road, London, E.C.

**COLOUR SCREEN-PLATE TRANSPARENCIES.**—No. 21,684. 1907. The invention relates to the production of continuous-tone three-colour prints and sets of negatives from screen-plate transparencies. It is found that, even if the positives be prepared by contact film to film with the colour negative (in which case such positives are markedly discontinuous in tone), sufficient continuity of tone may be obtained by preparing prints from the same by a process involving transfer of dye from a gelatine print, plate, or the like to gelatine-coated paper or the like, such as the pinatype process. The diffusion of the dye gives the required continuity of tone if the grain in the colour negative be fine enough. Satisfactory prints can be obtained in this manner from Autochrome plates with remarkably little loss of definition.

In obtaining prints in this manner the high-lights are kept clean, whilst the tendency to dilution of the shadows by white may be practically eliminated.

Substantially continuous tone-negatives can be prepared from screen-plate positives, and prints can then be prepared from such negatives by well-known processes. In order to avoid discoloration of the high-lights by black and by colour it is essential that the negatives should possess in a high degree continuity of tone in the parts corresponding to the high-lights. In preparing prints from coloured positives on screen-plates the requisite continuity of tone must be obtained in one operation—namely, in preparing the negative transparencies.

Furthermore, small errors in tone in the shadows are far less noticeable than impurities in the high-lights. It is therefore recommended to work from colour negatives. When preparing prints by the pinatype or other process there is no occasion to obtain continuity of tone in the positive transparencies, and it is preferable to use a stop having a much smaller aperture, such as one quarter inch or equal to one-thirtieth of the distance between the diaphragm and the colour negative, thus greatly improving definition. With screen-plates other than the Autochrome other stops may be used according to the grain.

When making enlargements the use of a heavily coated paper is desirable to assist the diffusion. Diffusion may be increased by heating the print whilst moist, also by retarding the drying. It will be found that each grain in the colour negative is represented in the positive transparency by a spot the size of which depends upon the diameter of stop used, but the centre of which is materially darker than the surroundings. By the use of a large enough stop the dark centres of adjacent spots may be made to blend, but in doing there is some loss of definition. Improved definition is obtained by the use of a diaphragm, screened so as to cut off some of the light at the centre, thus a stop having a star-shaped obstruction may be employed, or a graduated stop darkest in the centre may be prepared photographically. Such means are not required except when the grain is too large to be conveniently dealt with by diffusion in printing.

When employing symmetrical screens with spots in square formation a diaphragm should be employed with a square hole, shaded if

necessary as above described. In a similar manner a shaded rectangular stop may be employed with line screen-plates, and other forms with other formations, but where enlargements are not required it is preferable to adopt finely divided colour negatives and to employ diffusion in the printing process.

The invention also includes apparatus for the printing of the plates. Edmund Basil Wedmore, 167, Clifton Road, Rugby, Warwickshire.

**COLOUR SCREEN-PLATES.**—No. 23,812. 1907. The first claim is for "a process for the production of colour-screens built up of hexagonal elements, consisting in ruling parallel line screens with lines of suitable width, combining films produced from them in three layers, having the lines crossing at angles of 60 degrees to form clear hexagons upon a black ground, printing black and white screens from the combined film, and producing the colour-screen from the hexagonal black and white screen by successive printing and registration in the colours employed."

The starting point of the process is a transparent plate, such as that shown in Fig. 1, which is made photographically from a handmade original or by other means. It is found that an hexagonal screen, containing 100 to 150 cells per linear inch, produce as good

Fig. 1.

Fig. 2.

an effect, owing to the broken pattern, as line screens of 400 to the inch. The colour screens are printed in three operations in a registering frame, to be separately patented.

A less direct method of forming the hexagonal screen is illustrated in Figs. 2, 3, and 4, this process being based upon parallel line screens and giving a fineness of pattern limited only by the degree of fineness to which line screens can be made. The effect

Fig. 3.

Fig. 4.

produced by hexagonal screens of such fineness as this greatly exceeds that of any present method. Fig. 2 shows a plate in which the thickness of the black lines *f* is exactly half of that of the clear space *g* between. Two films of this type are prepared from a negative having the black lines double the width of the clear spaces, and the films are prepared so that they strip easily if required from their glass supports. The films are cemented together face to face, with the lines exactly at 60 degrees to each other, and on stripping off one glass a plate is left of the type illustrated in Fig. 3, with diamond-shaped spaces *h* between the crossing lines. This plate is again combined with a film of the type shown in Fig. 2, set at an angle of 60 degrees, with both the lines in Fig. 3 producing the plate of Fig. 5, in which hexagonal spaces *j* are left uncovered by the three sets of lines *f*. A positive from this plate

gives the black and white screen of Fig. 1, forming an original from which printing blocks or coloured screens can be obtained on glass or other transparent support for negatives and transparencies, or paper or other materials for positives and enlargements.

The specification also illustrates the various ways in which screens of hexagonal formation can be made from ruled lines or

Fig. 5.

Fig. 6.

screens of different relation of line to space. Thus, Figs. 5, 6, and 7 show a system of cells each of four hexagons, forming an interlocking pattern. The colour cells are marked  $a^3$ ,  $b^3$ , and  $c^3$  in Fig. 5, and this type of screen is probably the most perfect for photographic purposes. It is produced in a very simple manner from ruled screens, having black lines of twice the width of the clear spaces, which are combined in the manner already described to form the plate indicated in Fig. 7, leaving clear cells  $r$  at the desired intervals. From this positives can be obtained. By combining these the black and white screen of Fig. 6 is obtained,

Fig. 7.

with cells  $s$  of four hexagons, forming the original for the final coloured screen of Fig. 5.

For enlargements the paper or plate is prepared with the same designs in hexagons of increased size and coated with emulsion. Registration is obtained by including registering marks in the original screen. Or the negative may be reversed, registered by sight, the positive printed, and the image of the print reversed. James Mark Child, B.A., B.Sc., 47, Harrington Street, Pear Tree, Derby.

CINEMATOGRAPH LENSES.—No. 5,504. 1907. The invention consists of "a projection lens, in which an increased effective power of the back member, as regards bringing the beam of light to a focus

sooner, is obtained by separating it from the front member a distance equal to at least half of the focal length of the front member."

Thus in the figure a Petzval lens of the type used in ordinary cinematograph lenses, consisting of a cemented front combination  $c$  of 9 cm. focal length and a non-cemented combination  $d$  of 15 cm. focal length is modified by slightly decreasing the separation and is reversed as shown, so that the more powerful combination  $c$  is nearest the film. At a distance (which may be varied from .1 to 4 mm.) from the front surface, an achromatic combination  $e$  of 15 or 10 cm. focal length is added. The variation of the distance may be used to give greater or less magnification. If still greater magnification is desired, the two achromatic combinations,  $e$  and  $d$ , of 10 and 15 cm. focal length respectively, are used as shown. The distance between these lenses may be made as small as possible but may be variable to alter the equivalent focal length. The achromatic combinations are each made of hard crown and dense flint glasses, and are made with one surface, which is nearest to the film. Robert Alfred Ives, 21, Melgund Road, Highbury, N.

## New Trade Names.

TENAX.—No. 299,170. Photographic cameras and lenses. Optische Anstalt C. P. Goerz A.-G., 44 and 46 Rheinstrasse, Friedenau near Berlin, Germany, manufacturers. December 30, 1907.

## New Books.

"The Adventures of Cock Robin and His Mate." By Richard Kearton. London: Cassell and Co., Limited. 3s. 6d.

Another gift-book of the hedge-row from the pen of Mr. Kearton and in good time for the Christmas season. And this time the reading is for children of a rather tenderer age than the whom the author has hitherto addressed. We cannot help compare these many printed pages, almost each illustrated, with those of certain "Walter in the Woods" which in our infant days were offered to us as a convenient and agreeable introduction to the study of natural history. A somewhat priggish Walter was there instructed on the Sandford and Merton system, and caused to assimilate truths of nature all ready digested for him. Mr. Kearton is more scientific in his method, more educative, and a thousand times more entertaining. He presents Nature from the point of view of the very humiliated and frightened robin, of whose adventures, not to say amours, he writes in 240 pages of autobiography. The photographs and the reproductions are quite up to the standard of the previous volumes by the same author.

"Das Photographieren." By J. F. Schmid and R. Herget. Vienna and Leipzig: A. Hartleben.

This is a second edition of No. 168 of the well-known technical library of the firm of Hartleben, and is issued, at the price of 6 marks. It is a very comprehensive treatise on amateur photography, well arranged and indexed, and evidencing a knowledge of his subject on the part of the author. As befits its place in the series the volume deals more particularly with the chemical side of photography, and gives full formulæ for the preparation of developing and intensifying solutions, etc.

CRIPPLEGATE PHOTOGRAPHIC SOCIETY.—In view of the success attending the series of lectures given by Mr. Coe during the season, the Committee of this City society have considered it in the interest of members to enter into an arrangement whereby all have the opportunity of further benefiting by Mr. Coe's practical experience and teaching. Another new feature of this session will be a series of "One Man" shows, when a number of pictures by well-known workers will be exhibited in the lecture hall once a month. The meetings commence at 7.30 as hitherto, but the hall will be open at 7 p.m., thus a profitable half-hour may be spent in company notes and chatting over difficulties with other members. An excellent opportunity is thus presented for members to become mutually acquainted. The hon. sec. of the society is Mr. H. S. Cuming, North End Road, West Kensington, W.

## New Materials, &c.

**"CHIC" CHRISTMAS MOUNTS.**—The series of mounts issued under this name by the Kodak Company reach us this year in pleasing variety, and form a tasteful setting for photographs intended to be sent as Christmas greetings. They are of both the slip-in and paste-in pattern. Among the former No. 274, as shown in the illustration,

is a nice example of the series. It is of marbled surface-linen paper, with an embossed greeting in brown, and has a thick white inset mount with pale green decoration. The prices vary from 3s. to 3s. 6d. per dozen, 34s. 6d. to 40s. 6d. per 1,000; and other numbers of the series, including some of the calendars, are equally dainty in style and moderately priced.

## CATALOGUES AND TRADE NOTICES.

**MOULDINGS AND FRAMES.**—A new large list of Messrs. J. Epstein & Co., of Rupert Street, Bristol, shows the up-to-date selection of mouldings and styles of frames made and stocked by this leading firm. Messrs. Epstein can offer a variety in all classes and prices of frames, and their list, fully illustrated as it is, is quite worth the trouble of being charged for it.

**PHOTOGRAPHIC ALBUMS.**—A very fine and well-illustrated price list of albums for photographs and postcards reaches us from the Deutsche A.G., 90, Ritterstrasse, Leipzig, by whom a copy will be sent to any reader of the "B.J." The list also includes particulars of the firm's other specialties, such as slip-in and other mounts, film storage albums, folder and portfolio mounts, passe-partout materials.

**WRATTEN PLATES AND FILTERS.**—The 1908-9 list of Messrs. Wratten and Wainwright, Ltd., Croydon, is much more than a list. It is a series of what the newspaper editor calls "pithy paragraphs." These Messrs. Wratten, presumably through their scientific director, Mr. C. E. K. Mees, speak of many things—of fog and how it may be caused at exposure or in development; of markings on negatives which are the fault of the plate-makers, and of others which are not; of emulsion, which no backing remedies; filters, and a test for optical flatness; in short, of matters of importance to any plate-user. The list, which does incidentally give the prices of the Wratten products, is sent free, and is worth asking for.

**SOUTHAMPTON CAMERA CLUB.**—The Members' Year Book for the year 1908-9, has just been published, and shows this active seacoast society to be still strong in its policy of "presenting" members drawn from the leading workers of the day. Mr. S. G. Green has our congratulations on the production of a most attractive fixture list. Our readers within reach of Southampton should certainly apply to him at Oakdene, Highfield, Southampton, for a proposal as members of the Southampton Club.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### SATURDAY, OCTOBER 17.

Blackburn and District Camera Club. Exhibition of Member's Work.  
Birmingham Photographic Society. Annual Meeting of Midland Photographic Federation.

#### MONDAY, OCTOBER 19.

South London Photographic Society. Monthly Competition—Prints.  
Bradford Photographic Society. "Some Mountains and Glaciers of Switzerland." A. E. Hassé.  
Stafford Photographic Society. "Printing, Developing and Toning of Velox Paper." W. F. Slater.

#### TUESDAY, OCTOBER 20.

Leeds Photographic Society. "Lumière Autochrome Plate." Thomas K. Grant.  
Birmingham Photographic Society. Annual General Meeting.  
Hackney Photographic Society. "Some Ancient Abbeys and Churches of South Essex." C. Forbes.  
Manchester Amateur Photographic Society. "Some Points in Picture Making." G. E. Mellor.  
Chiswick Camera Club. "Carbon Printing." T. A. Coysh and H. S. Hopkins.  
Wimbledon and District Camera Club. "Carbon." Demonstrated. D. H. Magnus.

#### WEDNESDAY, OCTOBER 21.

Leeds Camera Club. "Making and Toning Lantern Slides." Rev. Henry W. Dick.  
Wimbledon Park Photographic Society. "The Selection of a Printing Process." W. Cheeseman.  
Croydon Camera Club. "A Ramble Round London." H. Creighton Beckett.  
North Middlesex Photographic Society. "A Few Hints on Copying." S. H. Bentley.

#### THURSDAY, OCTOBER 22.

L.C.C. School of Photo-Engraving, Bolt Court. "Large Size Engravings and Illustrations for Publishers." F. C. Batter.  
Handsworth Photographic Society. "The Production of Christmas Cards by Photography." E. G. Collins.  
Liverpool Amateur Photographic Association. "Platinotype Printing." C. F. Inston, F.R.P.S.  
Richmond Camera Club. "The Humble Beauties of the Flower World." E. Seymour.  
North-West London Photographic Society. "Gower." J. S. Fairfoul.  
Blackburn and District Camera Club. "Swiss Scenery." Dr. C. Thurstan Holland.

**GLASGOW PHOTOGRAPHIC ART CIRCLE.**—At the last monthly meeting of the Glasgow Photographic Art Circle a lecture was delivered by Mr. J. Craig Annan on "Photography as a means of Artistic Expression." In reply to the question that was often asked if photography can be a means of artistic expression, the lecturer said he would most unhesitatingly reply in the affirmative. Each art describes some æsthetic quality, and in this respect photography was no exception. At first, photography was at a disadvantage, as it was taken up by those who were for the most part of a scientific turn of mind, and they are generally devoid of artistic imagination. Prints were made by them and shown, and the accredited artists looked askance at the productions of the scientist. Many of the same class at one time thought Whistler as a painter an impertinent charlatan. It is being realised now that a new art-craft is being evolved with pictorial photography, one that has not yet achieved any commercial status. One cannot, of course, expect the patron to anticipate the process, and collectors are to be excused until the artistic side of photography becomes established. One of the earliest photographers, D. O. Hill, while an artist, was for a time much engrossed in photography, and found it a medium capable of expressing his noble thoughts. Slides were shown illustrative of Mr. Hill's work, also of Mrs. Käsebieber, Steichen, Robert Demachy, Clarence White, and many other prominent artistic workers. One picture of considerable interest was Mr. George Davison's "Onion Field," which with some others contributed to the formation of the now famous London Salon exhibition, and the banding together of the body of artistic workers known as the "Linked Ring."

**BATH PHOTOGRAPHIC SOCIETY.**—On Thursday, October 1, the annual meeting of the Bath Photographic Society was held at the Royal Literary and Scientific Institution, when a fair number of members were present, the President, Mr. Mowbray A. Green, being in the chair. Mr. W. J. Hallett, the hon. secretary, read the annual report, which stated that the success achieved by the Society during the first session had been well maintained, and a

goodly programme of meetings had been well attended. The session commenced with a membership of 95, and this steadily grew until 114 was reached, but through resignations the number now stood at 98. Mr. Lewin, the financial secretary, then presented the financial statement, which showed a slight deficit on the year's working. The report was adopted, and votes of thanks were passed to Messrs. Chester and Gould for their services as auditors. Mr. Mowbray Green proposed as President for the ensuing year the Rev. James Dunn, who was the senior vice-president. Mr. Hallett was re-elected hon. secretary for the third time. The following were elected on the council: Messrs. Rossiter, Lewin, Cooling, Harbutt, Burgess, and Woodward, and Dr. Symons.

## Commercial & Legal Intelligence.

**THE FREE ENLARGEMENT AT NEWPORT PAGNELL.**—Before the Newport Pagnell Special Petty Sessions last week Max Wolff, reproducer, framer, etc., of 6, Somerset Terrace, Duke's Road, London, W.C., was brought up on a warrant charged with false pretences—viz., with unlawfully and knowingly, by a certain false pretence, obtained of, and from one, Sarah Lacey, at Great Linford, on October 2, a certain photograph.

Sarah Lacey said she was the wife of Thomas Lacey, and resided at Great Linford. On October 2 prisoner called at her house before dinner, saying that he came from Mr. Thorneycroft's (photographer, Wolverton), and produced a picture, remarking that Mr. Thorneycroft had a commission from a large firm in London to enlarge a certain number of photographs, and wished to get a dozen from Linford; also, that they had taken (rented) the old post office in Newport Pagnell, and that they would get proofs by the middle of the next week; if she approved of them, and thought them good enough for framing, he would bring frames for her to buy, and that that would be the only expense she would be put to, the other (plates) being paid for. Witness then gave him her mother's photograph, adding that if she liked them she would have some more later on. Defendant Wolff took the photograph, which she valued at 1s., away with him, and she never saw it after.

By Inspector Anthony: He made no arrangement as to when he would return the photograph.

By the Clerk: He did not say what the cost would be. The enlargement produced I have not seen before till in court. My own photograph was cabinet size, and the enlargement is a proof. He (Wolff) produced something like the enlargement and showed me, but nothing was said about the money.

Mr. Chantler: The point is that she thought the enlargement was to be done by Mr. Thorneycroft.

The Clerk was of opinion that that really did not matter, contending there was no false pretence at all.

In answer to Mr. Chantler (chairman), Wolff said, "I'm prepared to give her back the picture; it lies in London, at six, Somerset Terrace."

Inspector Anthony: I may say they have brought forty-eight proofs to the district. (In explanation of "they," there was a good-looking young lady "colourist," apparently accompanying Wolff.)

Defendant said he was staying at "Speedwell." Witness did not give him an order; it was merely a speculation; if they liked to buy they could; if not, there was an end to it.

By the Clerk: I will hand the photograph to Inspector Anthony. The enlargement is nothing, and the frame is 12s.

The Chairman said they had decided to dismiss the case, as there was not sufficient evidence, and, pointedly addressing Wolff, said, "But you are sailing very close to the wind, going about the country representing yourself as working for people you are not."

Mr. Thorneycroft (adds the "Bucks Standard") was present, and strongly wished to give evidence, but in the circumstances it was thought unnecessary by the ruling powers, a somewhat peculiar feature apparently, as we understood he was the prosecutor and really the aggrieved party.

**EASTMAN KODAK COMPANY OF NEW JERSEY.**—The directors of the Eastman Kodak Company of New Jersey have declared an extra

dividend of 5 per cent. upon the Common Stock of the company payable December 1, 1908, to stockholders of record at the close of business on October 31.

**AT THE KINGSTON COUNTY COURT,** on October 9, before his Honour Judge Harrington, J. P. Catford, photographer, of 2, Lansdown Villas, Hampton Wick, applied for his discharge. The Official Receiver's observations were to the effect that the public examination of the debtor was held in April, 1902, when the liabilities proved amounted to £950. The assets realised £99, and a first and final dividend of 1s. 2½d. in the £ was paid. Mr. G. Washington F. solicitor, for the debtor, in asking that the discharge at the expiration of the minimum of two years, said the debtor attributed his bankruptcy to the failure of two companies with which he was connected, and from which he was expecting to receive a substantial salary. His Honour granted the discharge, subject to the usual suspension of two years.

**FOOTBALL COUPONS AND PORTRAIT ENLARGEMENTS.**—George Wm. Moore, photographer, 31, Princes Street, and Andrew Taylor, gardener, 59, Blackscroft, the two men who were implicated in the recent football coupon raid, again appeared in Dundee Sheriff Court yesterday—before Sheriff Campbell Smith—to answer to a charge of having on and between August 22 and September 19, 1908, opened, kept, or used a house at 31, Princes Street, and a shop at 60, King Street, for the purpose of money being received by them or on their behalf as a consideration for an undertaking or promise to pay money thereafter on events or contingencies of or relating to games of football, contrary to Sections 1 and 3 of the Betting Act, 1853.

Superintendent-Detective Lakie was the first witness called in the prosecution. He stated that, acting on information he had received, he obtained a warrant to search the premises occupied by Moore. Moore had personally and through his agents been distributing coupons, and in consequence of this, on August 25, Superintendent-Detective Lakie sent for Moore and warned him against continuing to send these coupons out. On that occasion Moore promised to stop it, but shortly after this several anonymous letters were received by Chief-Constable Dewar saying that the football coupon system was again going on. In consequence of that information a warrant was issued on September 18. On the following day Moore's house was visited, and the two accused and Moore's wife were discovered counting the coupons. The coupons bore the name of Dundee Portrait and Enlargement Club, and proved to be an order for an enlargement of any portrait, the inclusive price of which was to be 21s.—this sum to be paid by weekly instalments of 6d. Each of the customers was entitled to take part in a football guessing competition. The names of four football matches were printed on order forms, and the customers were entitled to fill these up with the likely scores. From the house in Princes Street and the shop in King Street they collected altogether 2,825 coupons, the dates of matches on these coupons ranging from August 22 to September 19. They also found a bag containing £14 6s. in gold and silver and a few coppers. A receipt book with the names of the winners was also found and confiscated. Books containing the names of the customers, the names of agents, and lists of prize-winners were discovered. From the papers confiscated it appeared that agents were paid a commission of 3d. on every 1s. they brought in. The back room of the shop was empty, and in the house the photographic materials were packed away in a press.

Questioned by Mr. Strachan, solicitor, who appeared for the accused, Mr. Lakie said he did not believe any enlargements had been sent out at all. A sum of £12 in money was paid weekly for prize-money. Enlargements like those offered by Moore could be obtained in Dundee, said Mr. Lakie, for a sum of about 10s., whereas Moore was charging 21s. for his enlargement. Taylor, when charged with betting by the officers, said he had only come to help his son-in-law to count the coupons.

Corroborative evidence was given by the other detectives who took part in the raid on Moore's house and shop.

Moore, on his own behalf, stated that he was a photographer and a portrait enlarger. For the past 18 months he had carried on his business in Dundee, and for 12 months previous to coming to Dundee he had carried on business as a photographer in Edinburgh.

In reply to a question by Mr. Strachan, Moore said he found it better to send the photographs away to be enlarged. Q.

number of his customers, he said, were perfectly satisfied with the enlargement without taking part in the competition, and some of the older forms were returned without the competition form being filled in.

A number of persons who had had enlargements made by the accused gave evidence to the effect that they were perfectly satisfied with the enlargements, apart from the competitions altogether, and that they considered the enlargement cheap at 21s.

The Sheriff found Moore guilty, but acquitted Taylor, his reason for convicting Moore being that his system was a combination of the lawful and the unlawful. A fine of £5, with the alternative of 40 days' imprisonment, was imposed on Moore.

**LEEDS FAILURE.**—At Leeds, on Monday, the first meeting of creditors was held in the case of Henry Morton Pearce, carrying on business in County Arcade, Leeds, under the name of "Morton's Star Photo Company." The liabilities were set down at £448, and his assets at £59. Failure was ascribed to heavy rent of business premises and bad trade. No resolutions were passed, and the case remains in the hands of the Official Receiver.

## News and Notes.

**ROYAL PHOTOGRAPHIC SOCIETY.**—The following lectures will be delivered at the New Gallery, those illustrated with Autochromes at 7.30, the others at 8 p.m.:

Friday, October 16.—Autochrome lecture, "The Thames from Kew Gardens to the Sea." By J. McIntosh.

Saturday, October 17.—"Some English and French Gothic Churches." By Henry W. Bennett, F.R.P.S.

Sunday, October 19.—Autochrome lecture, "The Thames from Cirencester to Maidenhead." By J. McIntosh.

Tuesday, October 20.—"Flower Photography." By E. Seymour.

Wednesday, October 21.—Autochrome lecture, "The Thames from Windsor to Richmond." By J. McIntosh.

Thursday, October 22.—"Life and Work on the Panama Canal in 1908." By Vaughan Cornish, D.Sc., F.R.G.S.

Friday, October 23.—Autochrome lecture, "The Thames from Kew Gardens to the Sea." By J. McIntosh.

Saturday, October 24.—"The Camera and the Sea." By F. J. Mortimer, F.R.P.S.

**LECTURES AT THE NEW GALLERY.**—The lantern lectures at the New Gallery during the Royal Photographic Society's exhibition have been well patronised, although in several cases they had been previously delivered before the Society, and were therefore not fresh to a number of the frequenters of the Exhibition. One of the raciest of the lecturers was Mr. George E. Thompson, of the Liverpool Amateur Photographic Association, who told the story of a photographic tour a little-known but not remote part of the Continent—the region of Cevennes, between Lyons and Marseilles, in Southern France. In this district there are wonderful volcanic formations, and the gorges of the river Ardèche present a wonderful spectacle to which ordinary monochrome rendering does not do justice. Mr. Thompson followed the plan of colouring his slides, and although this work was excellently carried out, the chief point of interest in the lecture was its literary grace and impromptu poetry, and amusing descriptions of a life en pension in a French spa. Why should the MS. so often be a mere tag to a set of slides? In the small towns of this part of France, says Mr. Thompson, the people are invariably amused watching the photographer at work, but they are never obtrusive, the country lasses are very "posable." Among other lecturers the Gallery have been Mr. W. Bickerton, who demonstrated how useful is the exercise of guile in photographing wild birds, and Mr. W. Harvey-Piper, who suggested that those who are looking for a scene in which to photograph and sketch might do worse than go to Northwold, the tiny cathedral town of Nottinghamshire, where the view from the chapter-house is of a kind unexampled elsewhere in England.

**GOERZ LECTURES.**—Messrs. C. P. Goerz, 1 to 6 Holborn Circus, London, E.C., advise us that they have a series of six different lectures for loan to photographic societies. The slides and lectures are

lent without charge, but each society is expected to pay carriage one way. The series includes "Sports and Pastimes with the Goerz-Anschutz Folding Camera," an exceptionally fine collection of seventy-four slides of athletic and sporting subjects, with a commentary on the slides by a well-known athlete; also hints useful to the photographer on fast exposures and development, and a few remarks on the relative efficiencies of focal-plane and lens shutters; "Telephotography," illustrated by 79 slides; "Stereoscopic Photography," accompanied by a number of stereoscopic slides illustrative of points referred to in the lecture, and specimens of stereoscopic photography. For viewing the slides six stereoscopes are sent with the lecture. "Pictures with the Goerz Lens," a collection of 112 slides of instantaneous, architectural, pictorial, and general subjects. "The Photographic Lens," illustrated by fifty-three lantern slides and two models. "What can be Done with a Hand Camera," illustrated by 107 lantern slides.

**AUTOCHROMES AT THE POLYTECHNIC.**—The opening night and social reunion of the photographic school of the Regent Street Polytechnic took place on Tuesday evening last, when a full house of students and their friends assembled to witness a series of projections of Autochrome transparencies, the majority of which were contributed by MM. Lumière, of Lyons, and represented certainly the finest Autochrome results which we have yet seen on the screen. They were projected from a lantern placed behind a semi-transparent screen, to the front surface of which a heavy gold frame was fixed with the object of giving all the appearance of a picture to the projected transparency. It says much for the ingenuity of Mr. Howard Farmer and his assistants that in the great majority of cases the picture fitted the frame, although the actual slides, we were informed, were of various sizes. The fact, however, that, at any rate to those at some distance from the screen, the gold frame was practically invisible, largely discounted, in our judgment, the trouble involved in its use, although in other respects the projection of the pictures was excellent in every way. Yet we would have wished to have been spared the constant alternation of two illuminated signs, one in red, green, and violet and another in white, on a screen above the projected Autochromes; the effect became distracting after an hour of it.

On the proposition of Mr. Farmer, a resolution of thanks and congratulation was passed, and was communicated to Mr. T. K. Grant for transmission to MM. Lumière. Mr. Grant, in acknowledging the compliment on behalf of his Lyons friends, also spoke as to the technical methods of treating the Autochrome plate, and urged the audience to adhere to the makers' directions, which, despite the great amount of published matter relating to the process, were still the best for the purpose.

**EXHIBITION OF CHILDREN'S PORTRAITS.**—Messrs. Speaight, photographers of children, are organising an exhibition of children's portraits. The exhibition will be held in the company's New Bond Street galleries next season, and in many cases the mothers will be portrayed with their children. The Princess of Wales and the Crown Princess of Sweden have both given their approval to the proposal by honouring Messrs. Speaight with sittings from their children in order that the portraits may be included in the exhibition. The Queen of Spain's private secretary has intimated that special sittings from the Queen and her children will be given to Mr. Richard Speaight in Madrid. Mr. Richard Speaight has been summoned also to Berlin in order that he may have sittings from the Crown Princess of Germany and her children.

**ENTRIES** for the forthcoming Hackney Photographic Society's exhibition will be received up to Monday, October 26.

**DEATH OF PROFESSOR VON JAN.**—Herr von Jan, well known in photographic circles as a photographer of the female form, was drowned on Tuesday last at Scilly. The professor had been staying at Scilly for some weeks with a young lady friend, and intended spending the winter there. When walking at Penderennis about noon he left the young lady reading, and descended the rocks to take photographs. Anxious at his long absence, the young lady went to the edge of the cliffs and saw his hat floating in the water. In great distress she ran to the town, but being unable to speak English she could not be understood until an interpreter was

brought. The rocks and coast were thoroughly searched, but without result. It is presumed the professor slipped and fell into the sea.

## Correspondence.

- \**We do not undertake responsibility for the opinions expressed by our correspondents.*
- \**Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

### THE RECENT EXHIBITION NUMBER OF THE "B.J."

To the Editors.

Gentlemen,—Just cannot resist writing to say how much the issue of the 18th inst. was appreciated. The accounts of the R.P.S. and Salon exhibitions were excellently done, the sprinkling of gentle sarcasm gave them spice.

It would be impossible to write about the "Links" in a style as serious as they take themselves, so the alternative is to treat them humorously.

The groups of the selecting committees were extremely interesting, for the reason that the names of Major-General Waterhouse, Beck, Wall, Newton, Lewis, Mees, and Mummery are well known in the U.S., and it was almost like meeting them socially to see them in the easy attitudes in which they were shown.—Yours sincerely,

S. H. HORGAN,

Ed. "Process Engraving Notes," "Inland Printer."

602, River Street, Hoboken, N.J., U.S.A.

September 29, 1908.

### RETOUCHER'S THUMB.

To the Editors.

Gentlemen,—I shall be glad if you or any reader of your paper can recommend any treatment which may benefit me. My thumb has almost become powerless through, I presume, retouching. The doctor recommends me to massage it, but that does not appear to be producing much improvement. Perhaps some of your readers have been in the same predicament, and will be able to give me some advice, for which I would be extremely grateful.—I remain, respectfully yours,

ARTIST.

### THE 6 x 4 PLATE.

To the Editors.

Gentlemen,—We notice in your "Answers to Correspondents," of your issue October 9, that a gentleman is inquiring whether cameras are obtainable to take plates 6in. x 4in., which he notices are now being listed by some plate-makers. The size in question is very little different from the size 15 x 10 cm. (actually 5½ x 3 15-16), which size is being introduced on the Continent as a substitute for the present so-called postcard plate. As you know, the latter is either 5½in. x 3½in., or 5½in. x 3½in., and, although for certain subjects it is a very pretty and pleasing size, it is not large enough to print on the standard size postcard without the use of a mask. The 15 x 10 cm. plate preserves the shape of the postcard plate, but has the great advantage of printing right out on to the standard size of postcard without the use of a mask, and leaves no white margin on the card. When the whole of the plate is printed from, the size is very little smaller than cabinet, but the camera is very much less bulky than a ½-plate.

Of course, in practice it is very little use speaking of the advantages of particular sizes of plates unless cameras of the same size are readily obtainable. The "Pocket Tenax," which we introduced this year, is made to take this size of plate, and we expect we shall be able to deliver early in December the "Goerz-Anschutz" folding camera for 15 x 10 cm. plates also. It may be pointed out that if the worker at any time experiences a difficulty in obtaining plates of this size, that the slides will, by means of the adapters which are

supplied, take the 5½ x 3½ plate, and the film pack adapters take the regular Premo film pack 5½in. x 3½in. The information given in this letter may perhaps be of use to your correspondent, and that is our excuse for addressing you.—We are, dears Sirs, yours faithfully  
1 to 6, Holborn Circus, London, E.C. C. P. GOERZ.  
October 12, 1908.

### THE THAMES COLOUR PLATE.

To the Editors.

Gentlemen,—Your friendly little criticism of the above in last week's issue, raising the question as to whether transparency in colour screen plate might be to the detriment of the delicate tints and half-tones, is worthy of a little discussion.

Is it not time for colour-screen workers to recognise that the plate which on close examination gives delightful half colours and tints is not and never can be the best suited for lantern work? The artist who paints the small picture would, if called upon to reproduce for a poster, sacrifice much of the detail and go for broad and striking essentials. And the poster in art is the projected image in photography. It seems to me that the worker should make up his mind which of the two he wants, and expose and develop accordingly. If this is not done, there is another course, a sort of half-way house. Most of the rooms used for lantern work are not so large that a smaller display on the sheet would be a drawback. I remember some Autochromes of Mr. Malby's that were beautiful on a circle about 3ft., but which caused him to tear his hair when they got a circle of about 8ft.—Yours faithfully,  
OLIVER S. DAWSON.  
254A, High Holborn, London, W.C.  
October 13, 1908.

## Answers to Correspondents.

- \**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*
- \**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- \**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.*
- \**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24 Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, Two unmounted copies of each photograph must be sent with fee.*

### PHOTOGRAPHS REGISTERED:—

COPYRIGHT.—A local chemist has taken to having portraits copied and enlarged, and underselling us, and is now showing an enlarged copy of a local celebrity copied from a card which we have issued from a copyright group of ours. What is our course to pursue to put some check on this sort of thing, which is a serious matter for us, as a large proportion of our business the result of many years' experience, is in pictures where copyright is valuable. This is a small town, and the offender is intimately connected with us socially. So we feel that if we allow him to play fast and loose with our work it will damage our prestige and encourage others to do the same. At the same time we do not wish to appear arrogant and make bad friends. "OXON."

You appear to be over-indulgent and to be paying a high price for peace. Your best course is to register the copyright.

in subjects which you think are liable to be pirated, and you can then deal firmly with a case of infringement and teach the offender a lesson. The reproduction of one portrait from a group is equally an infringement.

**MICROGRAPHS.**—Can you very kindly help me in the following matter? I have been endeavouring to produce some of these tiny micro-photographs, which can be purchased at the makers of microscopic slides, etc., and which are viewed through a microscope. I have been using iodised collodion, sensitised as usual, and developed with pyro. The results have been fairly good, but are not at all equal to what it is certainly possible to produce. Some years ago, a well-known microscope expert, the late Mr. Dancer, produced exceedingly perfect slides, which would stand great magnification without displaying a coarse grain, and it appears that the really fine slides still sold were produced by him. Those made by others show a coarse grain when magnified to a considerable extent. There is, of course, no secret in the procedure of photographing a negative by the aid of a microscope on to a tiny wet plate, but the difficulty seems to be to produce slides of the exceedingly fine grain referred to. I have heard that it is possible to produce these slides by the aid of the albumen process, and that it will give finer results than collodion. Can you give me any particulars as to its preparation, the proper developer, and the relative speed as compared with collodion? I shall be very grateful for any such help, as you may imagine.—BROMIDE.

See article on another page.

**PHOTOGRAPHS ON IVORY.**—Will you kindly let me know how photographs are transferred on to ivory?—MINIATURIST.

See article on another page.

**H. COLLINS.**—Other things than iron specks in the water will give rise to such spots, e.g., dust of developer, such as pyro or amidol, settling from the air on to the prints. This may occur from spilt developer drying up on the floor or bench. A suitable white spotting medium is that sold for process use as "Ullmanine" by Penrose and Co., 109, Farringdon Road, London, E.C., in bottles from 1s. upwards. Such spotting is not being generally done. If we can be of further assistance write us again.

**ARTIST.**—We can only advise you to consult another doctor and obtain a letter to a good hospital in your part of the country.

**H. S. BURTON.**—The publisher is Otto von Holten, Berlin. We do not know the price. Perhaps you had better address the publisher, c/o Herr R. Dührkoop, 10, Unter den Linden, Berlin.

**A. A.**—Try Philip G. Hunt, 332, Balham High Road, London, S.W.

**MR. BURTON.**—The author writes: "I can only say—at any rate for the present—that the plates I had in mind were the 'Royal Standard' and 'Mawson,' but since writing I have tried one or two other makes and find very little difference in length of time for full development. I may remark, however, that when the same make of plates is used and varying exposures are given on the same subject a remarkable difference is the result in point of time of development and density. The correct exposure should be given as far as is possible to do so."

**COPYRIGHT.**—I am about to take a sitter whose portrait will be copyright. Do I require to get him to sign an agreement giving me full legal right to publish his portrait? If so, would you please give a simple form of words which will answer the purpose, and which I can get him to sign when he sits.—AXME.

Better adopt the following, which is that recommended by the Professional Photographers' Association:—

To Mr. A. Darkslyde, Photographer,  
22, Cathedral Street, Canterbury.

In consideration of your allowing me a reduction from your usual terms for taking photographs of me, or on my behalf, this day, I hereby agree that the copyright in such photographs shall be reserved to you, and that I will not deal in any way with the photographs to prejudice your interest in the copyright.

Dated June 30, 1902.

WM. WIGGINS.

Witness: Lucius Light, Sunlight Villa, Canterbury, Clerk.

**AGAINST THE LIGHT.**—I should be pleased with a little advice on the following:—I have by me some very pretty and effective

photographs which are perfect renderings of seascapes and river scenery, with evening or night effects. The supposition is that they are taken by moonlight; but they are really sunlight pictures taken against the source of light. In some, the sun is visible, in others where the sun is behind the clouds, an additional charming light and shade effect is obtained. In each, there is a pretty effect by the reflected light on the water; full of sparkling ripple and detail, the beauty of which is well marked by its contrast with the surrounding, almost detailless, shadow. The shadows, although nearly black in places, are not weak and wanting, and show just that certain amount of details which gives such charming realism. (1) Would it be necessary to fix a tube in front of lens to prevent the plate from being fogged? (2) Would a backed plate be necessary—rapid or slow? (3) For a crimson sunset what brand of "Isochromatic" plate would be to advantage? (4) Would a very rapid shutter exposure be necessary, so as not to lose the sparkle of the reflection? (5) For developing, which would be best—a pyro-soda developer with a trace of bromide but well diluted, or a fast working pyro-soda developer with no bromide, but rich in both soda and pyro? My idea is to obtain sufficient detail and strength in the shadows without the brilliant high-lights becoming too dense.—C. WILLIAMS.

(1) With almost every lens it will be advisable; with some, indispensable. (2) Yes. We should take a medium speed. (3) Any iso brand of plate would be suitable. (4) Not more rapid than 1-50th of a second. (5) We should prefer the latter, but any developer which does not easily give a very hard negative would be suitable.

**YOUNG ARTIST.**—(1) We should say your predecessor received only the usual circulars, etc., from the trade houses, and as these will, of course, continue to come to you we cannot see that it is necessary for you to advertise. In any case the mediums which would most benefit you would be those in your own neighbourhood, but money spent in this way is largely wasted if the advertising is not done systematically. (2) Re Christmas trade you should apply to Messrs. Walter Pearce and Co. for their circular or booklet, produced with the object of creating trade in this direction. (3) There is scarcely a subject which is not at some time or another, and in some journal or other, available for reproduction. Your question as you put it is too general for us to answer.

**DIAMIDOPHENOL.**—I am a fairly large user of diamidophenol, chiefly for bromides, my formula being: Soda sulphite, 1 oz.; diamidophenol, 1 drachm; water, 1 pint; potass bromide, q.s. (1) This is so easy to remember, but I find that it stains my finger-nails quite black after a few days' use, and should like to know a way of preventing this. I was interested in the recent articles, but was rather bewildered by so many formulæ. I thought possibly an acid formula might prevent stains. (2) The acid bisulphite of M. Balagny is presumably the lyé, but I cannot get it easily or cheaply here. Would a saturated solution of sodium bisulphite answer the same purpose? Potass. metabisulphite is so much more expensive. (3) I should be glad to know which of the many formulæ would best answer my purpose (if any), and what are the other advantages of adding acid. A professional can hardly make the various proportions for exercising control as in M. Balagny's article, but wants one reliable all-round formula.—D. B.

(1) The stains produced by diamidophenol are very difficult to remove—in fact, we know no way of removing them quickly. The best way to prevent them is to use plate-lifters and finger-stalls for handling the plates. The acid formula is, we think, rather less liable to stain than the old formula, but it is still capable of giving very effective stains if you give it the chance. (2) Bisulphite solution is supplied in this country by the Lumière Company, or by Clarkson, of Colchester. It is a saturated solution of sodium bisulphite, but one of probably greater purity than you would be likely to reach by dissolving the commercial bisulphite. (3) You can judge better than we can which of M. Balagny's formulæ would best suit your purposes. We use the following formula for bromide work, intensification, etc.:—

Soda sulphite .....	1 ounce.
Potassium metabisulphite .....	1 drachm.
Diamidophenol .....	40 grains.
Potassium bromide .....	5 grains.
Water to .....	20 ounces.

The acid developer gives cleaner results when used several times

in succession, and can be used for a longer time. One of the principal advantages is the fact that the bisulphite preserves the sulphite, so that a strong stock solution containing all the ingredients, except the diamidophenol, can be kept for a very long time.

E. J. E.—(1) A and B. For distant views you can use long focus lenses if you have a long base and no near objects, but there will be no relief with a separation of 3½ in. Very distant objects may require a separation of half a mile or so. If near objects are also included a small separation is necessary, so that it is impossible to get relief in all planes of a long-range view. For objects three miles away a separation much under 100 yards will be useless. Seven and a half inches is a somewhat long focal length for ordinary stereoscopic work. We regard it as about the maximum focal length of use with ordinary separations and plates of the usual size. (2) (A) It would be absurd to expect an anastigmat to give as good definition as an anastigmat, or a cheap anastigmat to be quite as perfect as one of the highest quality; (B) we should prefer  $y$  or  $z$ , though  $x$  is very good, but with a reflex more rapid lenses would often be serviceable.

REPRODUCED NEGATIVE.—In a recent issue I saw you recommended for the reproduction of negatives the plan given on page 838 in Almanac, 1908. This is probably rapid. I should like to hear if you think it better or as good as making an ordinary positive in contact and then from it printing a negative in contact, or doing the same by transmitted light in the camera. I have often found that a good positive made by transmitted light has brought out details better than a P.O.P. print.—NEGATIVE REPRODUCTION.

We should certainly prefer the positive and second negative method, particularly if a carbon positive transparency be made.

ARTIFICIAL LIGHT AND COPYRIGHT.—Some months ago I called at a studio to inspect a certain artificial light. The proprietor kindly took me a double negative and made me a present of same, which I brought away with me. Upon calling at a wholesale firm who sell a similar light, I showed them the negative, which I thought might interest. They then offered to dry it and send by post the following day, but I had to write for same and did not receive it until a fortnight later. I have lately learnt, through my friends who have seen them, that untouched prints from the double negative were printed by this firm and used for business purposes without my knowledge or consent. Is this legal? Can I take any steps, if so, what? I might add they now inform me that the gentleman who took the negative is in their employ. I do not credit this, as he was not using their light, and no mention was made of the fact.—NEGATIVE.

The legal position, as regards copyright, is that the copyright has lapsed altogether in the subject, the negative having changed hands without registration of the transfer of the copyright. The firm, we fear, cannot therefore be proceeded against for infringement, though their action does not seem to be justified by the circumstances you have described.

SPOTS ON PRINTS.—Please state what may cause the small yellow spots on enclosed photograph, which has been taken some three years. Salt bath used before toning (sulphocyanide bath), prints fixed in hypo 9 oz., water 3 pints, for ten minutes, prints being turned all the time, and were washed in running water for 1½ hours. The overflow of washer was at the top. I may mention about thirty prints were fixed in above quantity of hypo. I have had postcards with same spots appear in about six months: postcards fixed for fifteen minutes. Please say how much hypo is required for, say, fifty postcards fixed in same dish, and how long for fixing. Do you recommend salt bath before toning?—F. C. D.

The spots appear to be due to chemical dust that has settled on the prints at some time or other. Possibly hypo dust. A salt bath is certainly advisable. Fix for ten to fifteen minutes. An amount of hypo solution sufficient for fixing a dozen or so prints simultaneously should contain quite enough hypo salt for fifty, but in any case it is a mistake to economise hypo. About a pint of 15 per cent. solution should be enough in theory.

D. M. EDWARDS.—Your lens does not seem to be of quite sufficient focal length to cover a postcard properly. In No. 1 the light patch may be caused by uneven development due to pouring

developer on centre of plate. Nos. 4 and 5 strike us as being prints from foggy negatives, while 3 is either over-exposed or under-developed. No. 2 is stained, probably owing either to use of partly exhausted developer, or to neglecting the use of an acid fixing bath. We will return postcards on receipt of 1d. stamp for this purpose.

WOODBURYTYPE.—I want to make some gelatine reliefs, so as to obtain an image in high relief when finished, though not for the Woodbury process proper. I made the tissue strictly according to a formula published a few years ago, using "Nelson's Amber Gelatine." The tissue looked all right when it was dry, though the drying took quite three days, as the film is so thick. I was quite unable to develop it when printed, even after soaking for an hour or more in water as hot as the hand could bear. Three or four lots have behaved in just the same way. Can you, through the "Journal," tell me the cause, or get me over the difficulty?—CONRAD.

The trouble is due to the tissue becoming insoluble during drying. Woodbury films should be dried in a drying box over chloride of calcium, so that they become dry in from eighteen or twenty-four hours at longest. It is very little use attempting to dry these thick films in an ordinary room.

F. SIMPSON.—If the carbon tissue has become spotted with mildew through being stored in a damp attic it will be a waste of time to attempt to use it. It is true that the mould can be wiped off and leave no mark behind, but it would show in the finished print. The only thing to do with it is to consign it to the dustbin.

N. S.—If when you purchased the business there was no agreement made that the previous owner of it was not to open another in the neighbourhood, you can do nothing. As it is, he can start another next door to yours if he likes, and you cannot prevent him. The fact that he represented to you that he was going abroad goes for nothing. Persons in buying a business should bind the outgoer, under a penalty, not to open another within a certain area, and within a certain time, or they may find themselves in the same position as you are.

A PAGEANT SOUVENIR.—Messrs. Debenhams, of the County of Gloucester Studios, have recently completed a remarkable photographic souvenir of the historic pageant recently held in Gloucester. It is a picture 96 inches by 50 inches of the massed Episodes. Each of the figures in the enlargement has received individual treatment and been coloured by hand, the work in this connection occupying several weeks. In regard to their work as official photographers to the Pageant, Messrs. Debenhams write us:—

"Only those who have experienced the responsibilities of the post can have any idea of the work entailed in order that the event should have a permanent record, which should be a credit to any professional photographer who takes an interest and pride in this work. In our case, our staff during Pageant time numbered over 70 hands. We would mention that if our experience would be of any benefit to any brother professionals, with pageantry work in view, it is entirely at their disposal."

\* \* NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The "free portrait" canvasser has now been prosecuted by the Inland Revenue, not for fraud upon the public, but upon the Government in using to take out a pedlar's licence. The case is important, and we trust that photographers have everything to gain by bringing our case on page 808 and the report of the case (on page 819) before the eyes of their local Police and Inland Revenue officers.

Lantern-slides and Bromide Prints direct in the Camera. Mr. Douglas Carnegie gives working details of a method for producing satisfactory lantern-slides and bromide prints without the intervention of a negative. He employs a bichromate reversing solution, but takes advantage of certain facts to avoid the general procedure on re-development of the positive silver image. (P. 811.)

Rev. F. C. Lambert, in "Photographic Scraps," has advised a permanganate method of reversal for enlarged paper negatives direct on small negatives. (P. 815.)

In "Photo Notes" a modified reversal process is recommended by Mr. W. Morison. (P. 813.)

Mr. C. Welborne Piper, in discussing the use of a swing back for reflex cameras, suggests a movement in which the front and back of the camera are linked together. (P. 809.)

Both the Salon and Royal exhibitions close to-morrow (Saturday), October 24, as does also the exhibition of photographs in colour by T. and O. Hofmeister and H. W. Müller, at the house of "British Journal."

The awards at the Franco-British Exhibition in the photography are given on page 814.

Some of the precautions necessary when using a focal-plane shutter with a very narrow slit in order to avoid markings on negative are mentioned on page 808.

M. Lumière and Seyewetz have published the results of tests extending over a number of years) of prints toned in the combined "other baths," and have confirmed their previous views that when used properly the combined bath gives permanent results. (P. 810.)

The use of cellulose as a means of printing from wet negatives has been patented. (P. 816.)

## EX CATHEDRA.

### A Reversal Process for Lantern Slides and Paper Prints Direct.

We may direct special attention to the article by Mr. Douglas Carnegie which we publish on another page, since it describes a technical process of photography which many workers have already aimed at bringing to a successful issue. The use of the process in the making of a lantern-slide direct from a drawing or other original without the intervention of a negative must surely be a gain to the lecturer and commercial slide-maker, whilst the facility of carrying out the process in the case also of bromide paper suggests new opportunities for portraiture of the while-you-wait order. The most rapid bromide paper is still rather slow for portrait exposures, but not so slow that the process cannot be used in good indoor daylight for portraits direct on any paper of the bromide class.

\* \* \*

### The "B.J." Almanac.

As briefly announced last week, the pages of the "British Journal Almanac" for 1909 are now closed so far as concerns the writing or acceptance of copy. The remainder of the present month is occupied by the make-up and actual printing of the volume, operations which have to be got forward with all possible expedition in order to leave time for the most lengthy process connected with the production of the Almanac, namely, the binding. The actual work of folding so many sheets, large and small, each to a total number of 25,000, is no light task, to say nothing of the pasting and stitching which complete the processes of the binder. Our publishers would, therefore, once more call the attention of all advertisers to the fact that insets to appear in the Almanac should be delivered to the offices of the "B. J.," 24, Wellington Street, London, W.C., not later than Monday, November 2.

\* \* \*

### Distant Stereoscopy.

A correspondent last week set us the impossible task of determining the proper separation of the lenses in a stereoscopic camera to give a stereoscopic effect when photographing a scene including both near objects and also distant mountains five miles away. Naturally, to show stereoscopic effect in the mountains a very big separation is required, but the same near objects cannot be included on the two plates excepting when the separation is small, therefore it is impossible to obtain a stereoscopic effect throughout the whole picture from the foreground to the distance. A compromise is essential, and as a rule we consider the near objects and let the distant ones take care of themselves. If we use a wide separation we can obtain considerable relief in the distance, but then the foreground becomes confused; if, however, we adopt a small separation suited

to the foreground objects there is no confusion anywhere, and it will be found that the distant mountains recede to their proper distance, even though they themselves show no more relief than would be observable in the natural scene. On occasion we may want relief in these distant mountains, even at the expense of a confused foreground, and then we can arrive at approximately the proper distance of separation by applying the rule given by Dr. Porter in his paper on Stereoscopy read before the R.P.S. a year or so ago. The distance is governed by that at which stereoscopic relief ceases to be visible to ordinary vision. This is a somewhat debatable distance, but Dr. Porter fixes it at 43 feet. If then we want the separation that will be necessary to show relief at 5 miles we work out the following rule-of-three sum:—As 43 feet is to 5 miles, so is  $2\frac{1}{2}$  inches to the distance required. The distance of  $2\frac{1}{2}$  inches is the normal separation of the eyes, which is another factor that concerns the problem. The rule is approximate only, and we need not be particular to a few inches in the result, which is about 108 feet. It is sufficient to say that less than 100 feet will not be enough to show full relief; and that it will be best to keep well over that dimension. We regret to see that in our answer to our correspondent we wrote yards instead of feet. If 100 feet is the minimum then 100 yards would be more than necessary.

#### Lantern Slide Binding.

Some little time ago we made some suggestions with regard to the precautions necessary to prevent the dewing of slides in the lantern, and we pointed out that the sources of moisture in the slide were the gelatine and the paper mask. We have recently received suggestions on this matter that seem worth consideration, even though we have not as yet tested their efficacy. The trouble is the condensation of moisture upon the cover glass, and it is suggested that if the cover glass is coated with gelatine on the inside the moisture will not condense into drops and therefore will not obscure the slide. That is to say, a fixed, washed, and dried lantern plate will make the best cover glass. The second suggestion is that a painted mask would be a good substitute for the paper mask, and that the paint can very well be applied on the inside of the cover glass. It certainly seems likely that a slide made up in this way should be immune to the dewing effect, but considering that the quantity of gelatine is increased and with it the source of moisture, we may doubt if the permanence of the slide itself would be increased. Possibly, however, if both slide and cover glass were dried and varnished an ideal method of construction would be arrived at. Moisture

may condense on the glass of the cover, even when slide is varnished, if a source of moisture is near, but would be much less likely to do so on a varnished gelatine surface. The painting of a mask is not a difficult operation if a simple rectangular opening is required, and we have frequently had to make such masks when rebinding clear daguerreotypes. On a gelatine surface the task is easier, and the varnish is far less likely to flake off. A very good varnish for mask painting is made of fine lac black and celluloid solution, but "Photopake" would be effective in the case of a lantern slide, and possibly more simple in use.

#### Printing Processes Old and New.

A writer in the lay Press has recently given a description of the salted paper process for the benefit of those of our readers who are ambitious to make their own materials. No doubt it is interesting to try the processes, but it is as well to remember that in many cases their disuse has been the result of progress, not of regression, and that very few, if any, of the abandoned printing methods are really worth reviving. So far as effect is concerned, modern methods give as much variety as can be wished for, and at the same time they enable us to more or less repeat the effects attainable by the old processes. In carbon printing, for example, by simply varying the quality and texture of the transfer paper used and the nature of the pigment, we can obtain an infinite variety of results, including some that are practically the same as salted prints, so far as appearance goes. There is, therefore, nothing gained by going back to the salted paper process, and we think that modern photographers would be wiser to increase their experience with the permanent carbon process rather than waste time over obsolete methods, the defects of which were well known to early workers. About the only one of the old processes that cannot be rivalled by modern methods is the daguerreotype, and though this gives quite unique results and has certain qualities lacking in more modern methods, its defects are so obvious that no one is likely to try to revive it. Surely carbon, platinotype, bromide, gum, and oil offer enough possibilities in the way of results. Perhaps the only modern process in general use that is not quite satisfactory is the useful P.O.P. with its numerous varieties. We cannot get on without a paper of this class, but one of more certain permanence would be desirable, and we are therefore not surprised to hear that of late albumen has shown signs of revival. This is a good printing process, and in several respects it is a worthy rival of P.O.P., but it appears to us to be about the only one of the

### THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1909.

Edited by GEORGE E. BROWN, F.I.C.

The forty-eighth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of over 1,000 pages, and the entire edition of 25,000 copies was sold out immediately. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1909 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

#### REFLEX CAMERAS,

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the

ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1909 will be modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1909 will appeal to photographers all over the world as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and, wherever practicable, new features of an informative nature will be added.

NOTICE—IMPORTANT.—Our publishers ask us to inform agents that it is advisable to place their orders for copies immediately, as considerably over half the issue is already booked, and a second edition will not be printed.

silver processes really worth consideration at the present time.

\* \* \*

**German English.** Here is a copy of a letter sent out by a firm of German moulding manufacturers, verbatim et literatim:—"Dear Sirs,—By looking through our book at the end of the year we find, to our regret, that we miss your agreeable orders since sometimes. By the present we allow offer our services again, and hope you could give to us a new order again. Please assure we will do our best to serve you at your satisfaction." Our amusement is somewhat tempered by the reaction that were we to attempt to write a letter in German would be still more amusing to the Germans. "Have you seen the penknife of your mother's aunt?" We wonder youthful Germans acquire their knowledge of English by such methods as seem to be the rule in language teaching in most English schools.

\* \* \*

**Packing Up Photographs.** It is a commonplace that a man is taken at somewhere near his own valuation of himself, and if we except cases of gross exaggeration there is much truth in the remark. We may certainly say that the man who does not respect himself does not command respect. This may be applied to the work produced in the commercial studio: if the producer has no respect for his own work he need not expect an educated up-to-date clientele to have any. One of the most effectual methods of showing how much respect he has for one's work is to despatch it to the customer, packed up neatly and securely in such a way, in short, that its delicacy and value are at once suggested by the adequate protection afforded to it in transit. Expensive wrappers are not necessary. A few large sheets of yellow cardboard, or the rigid corrugated packing, some white tissue paper, or the thin, smooth paper used by printers known as "white demy"; some smooth, tough, brown paper, and white twine of two thicknesses are all that is necessary, though the addition of a stick of parcels wax sealing, and some neatly printed labels will give additional finish. The actual parcelling up demands some care, for the paper must be drawn sufficiently tightly round the package to prevent its contents slipping about. The photographs—we are now referring to the larger mounts, for which ordinary postal wrappers are not so suitable—should be wrapped up in the tissue or white demy, and then placed between the strawboards, which must both be of the same size and truly rectangular. The whole is then enclosed in brown paper, the edge being sealed down in a couple of places before the ends are turned in and folded over. If the twine is passed round the parcel at each end and once round its length a secure package is made, and any friction on the surfaces of the prints is avoided.

\* \* \*

**Dark Light the Dark-Room.** From time to time we meet photographers who find the ruby light commonly employed in the dark-room not only inadequate in illuminating power, but productive of considerable irritation to the eyes after working for a short time. It is well known that lights of different colours exert varying influences on the brain, the effect of red, for example, on certain animals having given rise to the saying, "It's like a red rag to a bull." Whether the difficulty of working in a developing room illuminated with red light, arises from the influence of red on the brain, or whether from the fact that the retina is in some individuals very insensitive to red rays, the unpleasantness remains, and such workers would find a green light much more convenient and pleasant. Of course, the right

sort of green must be employed—a very deep cathedral green, very much nearer to yellow than to blue, being what is needed. Such green safe-lights are on the market, and one firm supplies a filter specially adapted for use, with plates sensitive to orange and red light, from which, however, one sheet of green paper may be removed if it is desired to employ such a light for the development of ordinary plates. Further than this, if workers would give attention to getting their exposures correct within reasonable limits, and adopt the method of developing with a constant or standard developer for a fixed time, keeping the dish covered during development, more light might be used, except during the few seconds needed for the placing of the plates in the dish, and the pouring on of the developer. In short, a little knowledge thoughtfully applied will very materially enhance the pleasure of work in the dark-room.

\* \* \*

**Considerations when Enlarging Portraits.** We recently discussed at some length the question of the size of head in so-called "life-size" portraits, this being a matter simply of the degree of magnification when making the enlargement, but there are other points which must be carefully borne in mind, not only when enlarging, but when taking the original negative from which the enlargement is to be made. It is not at all an uncommon thing to see harsh, crude-looking portraits, with excessive contrast, biting definition, and that peculiar outlining of the shadows with a line of light which has never been definitely accounted for, though it occurs generally in negatives erring slightly on the side of under-exposure, and, it has been suggested, is due to the developer absorbed by the film spreading from the slightly exposed shadow to the fully exposed high-light which utilises its activity. While it is usually accepted that all portrait negatives should be soft in contrast, this is an absolutely necessary condition in those intended for enlargement if pleasing results are to be produced, and, further, it is necessary to have a full scale of tones or perfect gradation from shadows to high-lights. Many workers over-develop their negatives to such an extent that, though fairly good contact prints may be obtained, in enlarging, the lighter half-tones become more or less lost. Skilled handwork will, of course, remedy such a defect, but this increases the cost of production beyond what, in many cases, is possible. More may be got out of the original if an enlarged negative is made, and where this is not worth while the negative may be reproduced same size, taking care to keep the new negative much softer in contrast. This is a simple matter, especially if a carbon transparency is made to work from.

\* \* \*

**Price Lists.** We are continually seeing the price lists issued by our professional friends, and are frequently surprised to find errors which should certainly never have been allowed to pass had the printer's first proof been carefully read. As an example, we have before us a price list which gives the following information with regard to imperial portraits:—

One Copy .....	1	1	0
Six copies .....	2	12	6
Extra copies, each .....	0	5	6

Many people, at first glance, may not notice much amiss here, but our experience is that when money comes to be spent, calculations are made, and it would soon be found that at this particular establishment it was decidedly less expensive to purchase one copy and then five extra copies at a total cost of £2 8s. 6d. than to go straight away for the six copies at £2 12s. 6d. The usual idea is that the price falls slightly as the quantity ordered increases, but

in this instance, to buy an odd copy as required is actually a more economical method than to get half a dozen straight off. Price lists must necessarily be somewhat confusing to the lay mind, understanding little of the various processes and of the difference in the amount of labour per print when making one or two prints only, and when producing several dozens from the same negative; but errors, and this is presumably such, can only increase confusion or necessitate subsequent explanation or correction.

\* \* \*

#### **Narrow Blind Slits and White Lines.**

When using a very narrow slit in a focal-plane shutter the resulting negatives often show white parallel streaks and lines passing right across the plate in a direction at right angles to the slit. The cause of these streaks is much the same as that of the black longitudinal lines often seen in a spectrum. That is to say projections exist on the edges of the slit, which projections are generally due to dirt in the case of the spectro-scope, and to fibres of the blind material in the case of the shutter. Inexperienced workers often fail to realise the importance of having a perfectly sharp-edged slit, and the fact that a very slight irregularity on the edges of, say, a  $\frac{1}{8}$  in. slit will produce lines on the negative is somewhat of a surprise to them. With metal-edged slits the trouble should never occur, it can always be prevented by simply keeping the slit clean, but with cloth-edged slits the defect is often serious, and the remedy is not so simple when the edges are slightly frayed. One expedient is to run a little varnish, say celluloid or shellac, along the edge and smooth the fibres down. A better remedy is to re-cover the edges with new material, but if this course is adopted, of course the old binding must be removed, otherwise the slit will be still further narrowed. Generally the blind material is a rubber cloth, and rubber solution is the adhesive used. In this case the old binding can readily be removed and replaced by fresh. But if this work of repair is found to be really necessary, we should strongly advise widening the slit a little. Of course, if the slit is adjustable this is not necessary, but many modern shutters are fitted with a series of fixed slits of different widths, and when this is the case we prefer to widen the slit and so save a recurrence of the bother. With a slit of  $\frac{1}{4}$  in. or  $\frac{3}{8}$  in. width a little irregularity is of very small consequence, but with a  $\frac{1}{8}$  in. slit it is not only important, but a difficult thing to avoid, and in our experience such a narrow slit as this can very generally be dispensed with. Of course, if the slit is doubled in width the speeds are halved, but even then it will probably be found that as high a speed as is likely to be required is easily attained. As a matter of fact a  $\frac{1}{8}$  in. slit is of little use at all unless an extremely rapid lens is available. With a reflex fitted with an  $f/4$  lens it may be very useful, for exposures of one-thousandth of a second then become feasible, but in a hand-camera with a lens working at an extreme aperture of, say,  $f/5.6$  or  $f/6$  such high speeds are usually out of the question. With an  $f/6$  lens we have found that a shutter intended to give one-thousandth of a second with a  $\frac{1}{8}$  in. slit will still give as high a speed as is practically useful, even though we have enlarged that slit to  $\frac{3}{8}$  in.

\* \* \*

#### **Black Lines in Focal-Plane Exposures.**

As already pointed out, white parallel lines on a negative situated at right angles to the slit indicate that the edges of the slit are either dirty or frayed out. Black lines similarly situated may indicate notches or nicks in the edge of the slit if a narrow one was used, but more often they are caused by pinholes in the blind. An old shutter frequently shows such holes, and they should

be looked for when the camera is under inspection in preparation for work; they can easily be stopped out with a small piece of blind cloth stuck on with rubber solution. This is the best remedy, as the patch is flexible and rolls up nicely with the blind, but in an emergency we have resorted to a small patch of black court plaster with perfect success. If the black lines prove to be due to a damaged slit, the remedy is much the same as before described in the case of the white lines. The damage must be repaired by rebinding the slit, while widening will prevent the lines appearing again.

### **INLAND REVENUE PROSECUTION OF PHOTOGRAPHIC CANVASSERS.**

It will be seen from the report which we publish on another page that the Inland Revenue authorities have recently instituted prosecution of a canvasser in Worcestershire who was found to be plying his business without a pedlar or hawkers licence. It was brought out at the Police court that a man coming from Clapton, London, took up his residence at St. John's, together with four other men. They were in the neighbourhood for about two months during which time they were accustomed to work the "free enlargement" fraud on the timeworn lines which unfortunately appears to have lost none of its ancient power in deceiving a gullible public. One of the gang first travelled round the district calling on publicans and other persons and offering to make, free of charge, an enlargement of any photograph, the enlargement to be hung up where it could be seen so as to serve, it was alleged, as some sort of advertisement. The visit of this first representative was followed by one from another of the party, who called with the enlarged photograph and with specimens of moulding for frames. Canvasser No. 2 exhibited the enlargement and intimated that it might be had on purchasing a frame for it. On the owner of the photograph objecting and maintaining that he was to have the enlargement free, Canvasser No. 2 explains that No. 1 must have made a mistake and usually a frame was supplied at a price sufficient to remunerate the vendors for the gratuitous inclusion of the photographic enlargement.

It will thus be seen that the method adopted by the canvassers in no way differs from that which is being practised by unscrupulous and dishonest persons in all parts of the country. No actual articles were offered for sale; the canvassers offered their work in frame-making for purchase, and thus brought themselves within the scope of the Act which specifically mentions the need of a licence by the hawkers "offering for sale his skill in handicraft." We may surmise that a disregard of this provision led these particular pedlars to refuse to take out a licence. Moreover—and this is a point upon which we would lay special stress—these canvassing gentry have the best reasons for not putting their names on any document which will bring them into relations with the authorities. As we have already pointed out, a year or more ago, the Pedlars Act of 1871, which is that now in force, contains certain provisions which make it very awkward to carry out a fraudulent game like the "free enlargement" swindle. In the first place, the canvasser who proposes to carry on his trade in a certain district must first show that he has been resident in the district for one month, and that he is a person of good character. His application, accompanied by evidence on these points, is made to the Chief Officer of Police who (or whose representative) is a person whom the canvassing swindler prefers not to meet.

Further, the pedlar's licence, according to the Act, is only available for the district for which it is granted. True, the holder of the certificate, on paying the sum of sixpence,

have it made available for another district, but in that case he must have it endorsed by the officer of the new district, again a meeting which the canvasser will avoid if possible.

Thus, two things are clear:—(1) That the obligation to take out a licence hampers the "free enlargement" canvasser; and (2) the nature of the business—the offer for the retail of his skill in frame-making—does actually bring a canvasser within the scope of the Act. We pointed out in our latter fact a year ago in our article,\* but it has not been until now that we have heard of a prosecution of the itinerant enlargement swindler by the Inland Revenue authorities, and therefore we would strongly advise every professional photographer to prepare himself for a possible visit to his town of a gang of canvassers by acquainting his local police with this decision of the Worcester Petty Sessions. The point which must be brought out is that the portrait canvasser is not only defrauding the public; he is also defrauding the Government by trading as a dealer without having paid the sum of five shillings, which

is exacted by the Inland Revenue Department. The present prosecution, therefore, does not represent simply a chance decision of the "Great Unpaid," or some officious act of Bumbledom, but is the outcome of proceedings instituted by Somerset House. The canvassers have made their trade so notorious that there is no likelihood of the most uninformed police officer denying the fraudulent character of the business. This he knows full well, but what he may not know yet will be very glad to be told, is the legal ground on which the movement of the canvassers can be nipped in the bud. The virtue of the Pedlars Act in this respect has now been confirmed by the authorities, and therefore a photographer can point out to his local police:—

1. That the portrait canvassers (sellers of frames) come under the Act.

2. That the necessity of one month's residence and of proving good character would usually make it impossible for them to carry on the business.

It is to the advantage of photographers, and particularly of those who rely on the poorer class of trade, to familiarise their local police authorities with these facts.

\* "The British Journal of Photography," August 9, 1907.

## THE MOVEMENTS OF A REFLEX CAMERA.

The most important peculiarity of the reflex camera is the fact that focus can be adjusted right up to the moment of exposure, and a study of the results of this characteristic fact shows several possibilities that manufacturers up to the present have neglected. For one thing, it renders possible movements of a kind that would be practically useless with a hand-camera of the ordinary type. Swing front and swing back can both be brought into play and taken the fullest advantage of, yet, if any, reflex cameras are at present provided with either movement.

Two of the main advantages of the reflex over the ordinary camera are that we can use a lens of far greater rapidity, and so a lens of much greater focal length. An eight-inch lens of  $\frac{1}{4}$  is almost useless in a  $\frac{1}{4}$ -plate hand-camera with which focusing is effected by scale, yet experience shows it to be a most valuable type of lens with the  $\frac{1}{4}$ -plate reflex. With the reflex, however, the size of such a lens limits the use of the rising front, and the great intensity renders the depth of field very small. Both these troubles can be got over to a certain extent with the aid of suitable movements, and it is therefore desirable to consider how the reflex camera can be modified to provide the necessary adjustments.

### A Suggested New Movement.

It stands to reason that the ordinary rising front movement of a reflex cannot be increased without a material growth in bulk. We must make the camera higher to get more rise, yet greater rise is distinctly desirable, for the long-focus anastigmat commonly used both requires and permits the use of a very considerable amount of vertical movement. What is wanted is clearly the substitute for a rising front that we sometimes employ in stand cameras. That is to say, if we tilt a hand-camera upwards, and then swing back and front until they are vertical and parallel, we can obtain all the effect of a rising front without using the actual sliding front movement at all, and by using the sliding movement as well we can gain a very big rise. Now, a reflex camera, like a stand-camera, can be fitted with either a swing back or a swing front, in addition to the usual rising front. If we have both swing movements, and also a means of linking front and back together, so that they will always be parallel, then the rising front difficulty

disappears. Such a parallel swing movement would be of no use in a hand-camera, because, when brought into play, the lens is nearer the plate, and focus is disturbed; but this trouble is of no consequence in the reflex, in which focus is adjustable up to the moment of exposure.

If, now, a swing back and swing front are both provided, we can get over the difficulties attending the photography of very high buildings, and we have also two ways of compensating for the want of depth possessed by the large aperture lens. To bring near and distant objects into sharp focus we can use either the swing back or the swing front. If the former, we may introduce distortion; but if the latter, we can avoid distortion altogether: therefore, the swing front is obviously the best movement for the purpose. To be able to effect this correction of focus, and also to obtain the big rising front movement, we must, therefore, arrange the swing front and swing back movements so that they can either be linked together for parallel movement or disconnected and used independently. This may seem a great complication, but there would be no great constructional difficulties, so far as I can see, and no very great increase in weight need be involved.

No doubt it may be argued that the one swinging movement alone should be sufficient; but if we consider the two cases of swing back alone and swing front alone, I think it will be evident that either movement by itself will be of small advantage in the particular case of a reflex camera, with which a very rapid lens is an essential feature.

The two difficulties we have to cope with are the inclusion of high buildings on a vertical plate and the compensation for want of depth.

With a swing front alone we can get over the depth difficulty quite effectively; but for taking a high building this movement is quite useless unless we also have a big rising front, which latter movement we cannot possess in the reflex. The high building difficulty is therefore unconquered if we have the swinging front alone. Next suppose we have a swing back alone. With this we can get over the depth difficulty, but at the expense of distortion. We can also get a high building on to the plate, but only at the expense of stopping down the lens, and generally this is the last thing we want to do with such subjects.

Of the two movements the swing back will do more than the swing front—that is, it will do two things, both imperfectly; but, while the swing front will do only one thing, it will do that well. On the other hand, the combination swing movements, that can be used either linked or separately, will do all that can be wanted as well as it possibly can be done. With them we can take the fullest advantage of a flat field lens of large aperture and great covering power, or we can humour the idiosyncrasies of a narrow-angle lens. The proper method of use would be somewhat as follows:—

#### Use and Construction.

Ordinarily the front and back should be linked together, so that both always move parallel, and the two should be actuated by one piece of adjusting mechanism. A single lever or knob could work both. In the case of a high building the ordinary rising front will be used first. If required, the parallel swing movement will then be brought into play; and if this proves inefficient, owing either to the extreme height of the building or the lack of covering power of the lens, the linking can be disconnected and a little extra movement given to either back or front as required: to the former if great height is the trouble, and to the latter if the lens is at fault. The amount of stopping down then wanted will be at a minimum, so the fullest advantage can be taken of the rapidity of the lens. In the other

case, of want of depth, the first thing to do is to disconnect back and front, and then adjust the front alone.

As regards construction, it is obvious that front and back can be kept parallel and yet separable for focussing purposes by parallel rule or lazy-tongs methods of linking. Any swing imparted to one will then affect the other. The front can be given an independent swing on the linked-up framework, and a similar independent swing can be given to the back. I think, however, that in practice it might be found that the independent swing to the back could be dispensed with, as the parallel swing movement would probably give sufficient rise to meet all cases of high buildings.

It is, of course, obvious that when a swing back is used in a reflex modifications must be introduced to ensure that the focusing screen shows the exact image that will ultimately fall on the plate. The mirror must always bisect the angle between plate and ground-glass; therefore either all three must remain always in the same relative position, or two of them must be automatically adjustable. It should be clear that a linked parallel movement of back and front is precisely equivalent to a big rising front. If this latter movement can be provided, then, with it, and a swing front, all the requirements are met. I very much doubt, however, if this can be managed without a great increase in bulk.

C. WELBORNE PIPER.

## ON THE ALTERATION OF PRINTS ON P.O.P. TONED AND FIXED IN THE COMBINED BATH.

In a previous paper<sup>1</sup> we have shown that the alteration in positive prints on gelatino-chloro-citrate paper toned and fixed at one operation in the combined bath appears to have been wrongly attributed to the presence of lead salts in the toning solutions. Prints toned in combined baths containing gold and lead, or even lead only, have proved to be as permanent to light and moisture as those toned with gold alone. We have shown that the indispensable condition for this permanence is the complete elimination of every trace of hyposulphite of soda. The presence of small quantities of this unstable body certainly gives rise to the speedy alteration in damp air of prints which have been toned with gold either with or without lead salts. The alteration of prints toned in the combined bath (with aid of lead salts) has seemed to us to be favoured by the acid reaction of the bath, but this cause can prove an active agent of the destruction of the prints only when the print is not completely freed from the hyposulphite.

The above experiments have so far not been confirmed by the test of time. The prints have been exposed to light and to air only for about twelve months, and therefore we have been able to draw from these experiments only provisional conclusions. But we have had under observation for several years past a number of prints, toned under the most diverse conditions and freed from hypo, which have resisted for one year the action of air and damp. We have examined these prints after their storage for seven years in cardboard boxes placed in damp cupboards. The following were the results of the examination:

1. No prints toned and fixed in a combined bath containing gold, either *with or without a salt of lead*, have suffered any change. All the prints washed free from hypo have retained their original vigour, whether the toning had been much or little.

2. On the other hand, all the prints toned in baths which contained no gold, but only a lead salt, have suffered more or

less severely. The toned prints, both those made with the toning bath containing lead pentathionate (no gold), which we have described as giving tones resembling those given by gold, and those made with the toning baths containing nitrate of lead, have equally shown strong yellowing.

3. The presence of lead in the toning baths, in the case of separate toning and fixing, has not detracted from the permanence of the prints.

4. The substitution of tin for lead in the combined bath containing gold (giving a bath which tones as well as that containing lead) has had an unfavourable influence on the permanence.

5. Lastly, prints fixed in a bath of hypo free from gold or lead, and to which has been added alum either with or without boiling, or to which a little alkaline sulphide has been added, have shown no alterations: the dull tones have been preserved.

In short, the presence of lead in some form or other in the combined bath containing gold, hitherto often considered to have been the cause of the fading of prints on P.O.P., does not appear to exert any unfavourable influence on the permanence.

The active factor is, as we have shown, the hypo retained in small quantities in imperfectly washed prints.

On the other hand, the use of lead salts alone in some form which, in the absence of gold, gives good results at the time of toning, should be abandoned in consequence of the change which such prints so treated afterwards undergo.

These results appear to confirm those which we have obtained by analysis,<sup>2</sup> and which have shown the complete absence of lead in prints toned in combined baths containing both lead and gold. Toning mixtures of this kind may therefore be employed with the same prospect of permanence which are given by separate toning and fixing.

# POSITIVE LANTERN-SLIDES AND PAPER PRINTS DIRECT IN THE CAMERA BY A SIMPLE PROCESS.

A process which would materially lighten the labour and greatly shorten the time required for the production of diagram lantern slides has long been a desideratum with the lecturer who aspires to infuse personality into his work; that is to say, with the lecturer who adjusts his slides to illustrate his theme instead of adopting the Procrustean method of compelling his treatment of the theme to fit the stereotyped slides purchasable on the market.

The most obvious way of shortening the procedure in lantern-slide making is to obtain the required positive transparency directly from the plate exposed in the camera.

My first essays in this direction, in which I applied methods of reversal similar to those adopted in Autochrome work, met with no success. On theoretical grounds I must confess I did not anticipate success for this mode of procedure, but practical trial so often confounds our theoretical anticipations that it seemed inadvisable to dismiss the matter without bringing it before the tribunal of experiment.

The plates chiefly experimented on in this connection were the "Kristal" gas-light plates—chosen because they appeared to me (whether rightly or wrongly) to carry a very thin coating of emulsion. In the preliminary experiments the plates were not exposed in the camera, but negatives were prepared by giving all exposures behind positive transparencies of line subjects. The exposed plates were developed, placed in a so-called reversing solution, re-exposed, and then re-developed. In no case, however, was the reversal of that complete character that the Autochrome-work looked up black and vigorous on a perfectly clear background, as should be the case with a satisfactory lantern-slide. The background was always fogged to a quite impossible and inadmissible extent, ring the changes of conditions and procedure as I would; and the only melancholy satisfaction accruing to me was that my anticipations of failure were fully justified.

The reason of this failure is not far to seek. Development is what chemists (of the older school, at any rate) would call an incomplete or balanced interaction, in the sense that however powerful the developer, and however prolonged development may be, there is still developable (unreduced) silver haloid present in the film when effective change has ceased. In other words, an equilibrium is finally established between reducible haloid and developer on the one side, and reduced haloid (silver) and oxidised developer on the other, so that moieties of the original factors of the change are necessarily represented in the final equilibrium system after effective development has ceased. It is impossible by means of a developer to reduce the whole of the exposed, and therefore reducible, haloid in a film to metallic silver.\* Consequently, after primary development and the application of a silver solvent—be it acidulated permanganate or persulphate—there is always, no matter how complete the exposure to which the plate has been subjected, some silver haloid left on the parts of the slide corresponding to the background, i.e., on those parts of the transparency where, after the application of the silver solvent, we desire to have clear gelatine. This residual haloid, of course, darkens during the secondary or reversing development, and gives a dirty slide.

\* It may be asked how, in view of the incomplete nature of the developmental reaction, satisfactory results are obtained in the reversal of Autochrome plates; for mere thinning of the film cannot alter the inherent incompleteness of the developmental process. I presume that, even in the case of the thin Autochrome film, reversal is not, speaking academically, absolutely complete. The following experiment would be informative. With the film towards the lens, fully expose on a white sheet of paper half of an Autochrome plate, the other half of the plate being meanwhile shielded from the light. Then develop, reverse, expose, and re-develop. If the reversal has been absolutely perfect, the exposed half of the plate should be quite free from veil and of precisely equal transparency with the unexposed half. It would be of much interest to know the result of such an experiment.

The incompleteness of reversal of the background in these experiments cannot be ascribed to the failure of the light during exposure to penetrate right through to the very back of the films, for when two plates in super-position were exposed behind the positive transparency the plate furthest removed from the source of illumination gave a strong negative on development—the light which produced this negative image having, of course, passed right through the film and glass of the first plate still in possession of strong photographic activity.

It follows that after treatment with the silver solvent the whilom negative is essentially a cameo in silver haloid. The portions of the plate, corresponding to the lines of the positive transparency employed, retain their original film density of silver haloid, while the background from which a considerable amount of silver has been first reduced and then subsequently dissolved away, is only more or less thinly veiled by residual silver haloid. This suggested the experiment of placing the plate in weak "hypo," after treatment with the silver solvent and prior to re-development, in the hopes that the thin background veil of haloid might dissolve completely away, while yet a sufficiency of the thicker haloid deposit representing the lines remained to give good opacity on re-development. But the hope was vain. The hypo has to penetrate the gelatine to reach the background veil of haloid, which is necessarily in the lower reaches of the film, and *pari passu* with this penetration the haloid representing the lines is dissolved away. Such a differential solvent action of the hypo as is here desired could only be effectively realised in the event of the background veil of haloid being situate in the upper portions of the film.

To turn now to a description of the modus of reversal that I have found suitable for the preparation of lantern-slides direct from the camera negative. The plates used in the experiments were backed "Imperial Process Plates." The plates were exposed on black and white drawings illuminated by limelight. The plates were developed in a metol-hydroquinone developer containing bromide, observing all the conditions necessary for the production of strong, hard negatives of a character suitable for the customary method of preparing lantern-slides by contact printing. It is better to over-expose the plate than to under-expose it; in fact, any considerable degree of under-exposure is absolutely fatal to the success of the process. After development the plate is washed in three or four changes of water, and then placed in the silver solvent which has the composition:—

Potass bichromate .....	5 drachms.
Nitric acid (puriss) .....	3 drachms.
Water .....	40 ounces

All the operations subsequent to the rinsing away of the primary developer from the film may safely be conducted in a comfortably bright yellow light.

In very warm weather it is advisable to dilute the above solution with once or twice its own volume of water, else opalescence, due to a curious pitting of the gelatine, is apt to supervene. A pitted plate may, of course, be made presentable by varnishing; but the drying of varnish is always a very slow process, and time is saved by making a fresh negative. After about two minutes in the "reversing" bath the silver from primary development is all dissolved; the plate is given a momentary rinse under the tap, and its surface lightly stroked with a mop of wetted cotton wool. (The bichromate solution is not washed out of the film.) The plate is now returned to the already used developer, rocked therein for half a minute, and then, while still under the developer, exposed to light.

From 20 to 30 seconds to the flame of an ordinary number 4 flat-flame burner, held about a foot above the developing dish, is a suitable exposure. The portions of the plate protected during primary exposure by the rebate of the dark-slide are the first to turn black; then the positive image appears and slowly gains density. It is essential that this secondary development of the plate be not pushed to the point of fogging of the background, for any background veiling that may form in this process is not (as in contact printing) on the surface of the gelatine, but deep buried within the film, and it is almost impossible to remove it without at the same time wiping out the more superficially disposed positive image. To avoid the possibility of stains, it is essential that the plate should not be fingered between the several stages of the process. The plate should either be manipulated with a plate-holder, or preferably all treatments and rinsings up to the final hypo bath should be performed with removal of the plate from the dish, which, for safety's sake, should be made of a dead-black material. After removal from the developer the plate is plunged forthwith into an acid fixing-bath, cleared by momentary immersion in a *very dilute* Howard Farmer reducing bath, and then washed.

It will be gathered from the fact that no intermediary thorough washings, sulphite baths, etc., are involved, that the process is a very rapid one. If there is urgency, the final washing out of the hypo may be hastened by placing the plate for a few minutes in 10 per cent. formalin solution, washing with four or five changes of boiling water, and then drying on a whirler.

It may be convenient here to tabulate the stages of the process in their proper order.

1. Primary development.
2. Rinsing.
3. "Reversing."
4. Return to developer, re-exposure, and re-development.
5. Fixing.
6. Clearing.

The positive resulting from this process is, of course, reversed as regards left and right, and due allowance must be made for this in spotting the mask and binding on the cover-glass, so that a rectified picture may be obtained on the screen.

It will be noticed after removal of the plate from the fixing-bath that the background exhibits a slight milky-white opalescence, due, I presume, to an oxide of chromium precipitated in the film from the acid bichromate silver solvent. This opalescence (which as a matter of supererogatory refinement I have vainly attempted to dissolve out of the film) is, however, of no practical consequence, as on drying the film it becomes quite imperceptible in transmitted light, and its presence can only be discerned in very obliquely reflected light. Consequently, it does not detract at all from the brilliance of the screen picture formed by directly transmitted light.

I found that this opalescence can be avoided if the nitric acid of the silver solvent be replaced by an equivalent quantity of sulphuric acid; but for reasons which will be given shortly in suggesting the *rationale* of the process, the substitution of nitric by sulphuric acid cannot be recommended in the preparation of line-work slides where "hard" effects are in demand.

If the secondary development is by misadventure carried too far, and incipient silver fog appears where clear background is desired, the slide may be reclaimed by careful reduction with the Howard Farmer reducer, followed, if necessary, by the now well-known rapid method of chromium intensification. The reducing-bath is made up as follows:—

Potass ferricyanide (saturated solution).....	1 dr.
Hypo solution (ordinary fixing strength) .....	1 dr.
Water .....	2 ozs.

Since the fog is buried in the depths of the film, the slide must not (as is the usual procedure in clearing) be immersed bodily in the reducer, but the solution should be repeatedly applied to the fogged areas with a pledget of cotton-wool, wash-

ings under the tap immediately following each application of the reducer.

As regards the *rationale* of the process, I am not prepared to speak otherwise than tentatively and suggestively. I believe that the failure of the background to develop up on secondary development is due to a combination of several causes. The action of the bichromate solvent results in the formation of a reddish-coloured, actinically opaque compound, which is adsorbed by those portions of the film (the background) from which silver has been removed. This adsorption-held compound (ultimately acted on by the developer during secondary development) behaves as a screen or safe-light, protecting the underlying haloid from the effects of the exposure of the plate prior to secondary development. The compound afforded by the sulphuric-bichromate solvent is nothing like so deeply coloured as that resulting from the nitric-bichromate solvent. Hence general background fog is much more likely to supervene when sulphuric acid is used as acidifying agent, and here is the reason why, in spite of the freedom from opalescence that the employment of sulphuric acid affords, I do not recommend it as the acidulating agent of the solvent bath when the production of hard black-and-white results is in question.

Again, since the bichromate is *not* washed out of the film before secondary development, and since the picture in silver haloid lies on the surface of the film while over the background the upper portions of the film are haloid free, it is easily seen that mere diffusion must also play an important rôle in the differential development accruing. While over the background portions the developer has to diffuse through a film of haloid free and bichromate-saturated gelatine before it can get into touch with silver haloid, elsewhere developable silver haloid permeates the film to its very surface.

Lastly, there are indications that the gelatine film is less permeable in those portions where there has been reduction of silver followed by subsequent removal thereof.

It will be noted that the method here described differs only in details of order of procedure, omissions of sulphite baths washings, etc., from methods which are already in use for the production of reversed negatives. But it is just the rigid observance of these apparently insignificant alterations of procedure that transmutates the character of the end product from a reversed negative to a reversed positive. There can be a novelty in procedure just as truly as in the reagents used.

Mr. George E. Brown has reminded me that there are occasions often occurring in the practice of the itinerant photographer where only a single copy (on paper) of the subject photographed is in demand. He therefore suggested that I should try whether the process described would work satisfactorily in the case of negatives of a general character obtained by exposing bromide paper in the camera. Clearly the applicability of the process to such practice would greatly economise not only time but also cost of production. The suggestion came just on the eve of my departure from home, but the few experiments I was able to make proved its practicability and promise. The paper experimented on was "Wellington" brand; the highly glossed "Enammo" variety proved the most suitable. I tried exposures which were obtained by multiplying the exposure given by Wellington's calculator for a plate of speed  $\frac{1}{4}$  by factors varying from 20 to 40. The smaller factors give darkly printed positives showing but little contrast in the shadows; the larger factors give lighter (weaker) positives showing greater contrast in the shadows. If, by inadvertence, too great an exposure is given, resulting in a very soft negative, it is advisable to use as silver solvent a bichromate solution acidulated with sulphuric acid and composed as follows:—

Potass. bichromate .....	1½ drachms.
Conc. sulphuric acid .....	20 minims.
Water .....	10 ounces.

In the case of bromide papers the illumination before secondary development must be less intense than in the case of black and

te lantern-slide work. I used a gas flame of about one candle. er placed thirty inches above the developing dish. Expo- s to this light was continued till the portions of the paper eected by the rebate of the dark-slide began to darken. ol-quinol developer was used of the same composition as e, saying that no bromide of potassium was added to it. prints will be found to be of a greyish colour when taken n the developer; they darken considerably when placed in fixing-bath. The tones on bromide paper resulting from the ndary development of this process are for some reason or er not at all pleasing, hence recourse was always had to sul- e toning. The procedure described by Mr. C. W. Piper the "B.J." for August 14, 1908, gives, in my opinion, the e results.

he pictures thus obtained are, of course, laterally reversed,

a matter of little consequence in portrait work, where the sub- ject is (more or less) symmetrical. With a view to the attain- ment of rectified positives of non-symmetrical subjects, trials were made in which the bromide paper was exposed film side away from the lens. Preliminary experiment showed that the exposure under these abnormal conditions must be increased thirty times. The results were as satisfactory as could be expected. Naturally the definition of these non-reversed posi- tives could not compare with the crisper definition of the re- versed ones, for the light must necessarily be scattered and diffused in its passage through the non-homogeneous paper sup- port to the film. Even so, the definition was still quite good enough for the purposes of portraiture, in which a certain amount of diffusion of focus is not an unqualified evil.

DOUGLAS CARNEGIE.

## ENLARGED PAPER NEGATIVES DIRECT BY REVERSAL WITH PERMANGANATE.

Appos of the above method of Mr. Carnegie's, the following article by the Rev. F. C. Lambert, M.A., may be quoted from the current issue of "Photographic Scraps."]

a reversal of an image by permanganate has been revived by use of a similar method in the Lumière Autochrome process, the procedure may now be more widely adopted. Iford slow bromide paper (or an Ilford "Ordinary" plate) is ex- posed (by contact or through the lantern) and developed—but not d—in the dark-room. The positive image is next dissolved and moved. The paper or plate is then again flooded with developer exposed to strong gaslight at the same time; finally it is fixed, shed, and dried.

strongly advise the beginner to be content with making a few tact experiments just at first, using bromide paper and a quarter- e original negative. A bright and plucky negative, but not too use, should be chosen. Put it in an ordinary printing-frame. In tact place a piece of Ilford smooth slow bromide paper. Make pencil-cross on one corner of the back of the paper. As a rough e give an exposure of 15 seconds at 4 feet from an ordinary 4 or 5 gas burner.

For development dissolve 8 grains of potassium bromide in one ce of water, that is one grain of bromide to each 60 minims of ution. Of this take 30 minims ( $\frac{1}{2}$  gr. bromide), 25 minims of inal, and water to make 1 oz. The positive picture should be ly developed, that is to say until a suspicion of the highest lights e be just seen on the back of the paper; very full development is ential to the success of the process.

The positive obtained will look too dark and too dense for any inary purpose. The print is rinsed and put into a saturated ution of common (potash) alum for a few minutes. It is then ed out, laid flat in an empty dish, and the alum bath is converted o a reducing bath in the following way:—To 2 ozs. of the satu- ed solution of alum add 1 drachm of a 20 per cent. solution of phuric acid and 10 drops of a solution of potass. permanganate, hich should give the whole a fine, full port-wine colour. The print immersed in this mixture and the image steadily dissolves. The print should be turned over once or twice and plenty of time owed for the bath to act thoroughly.

This bath should be made up fresh for each print, otherwise the e becomes badly stained. In any case it is probable that there ll be a little stain, but this can easily be removed by washing in weak solution of oxalic acid. Dissolve say 10 grains or so of oxalic cid in half a pint of water; immerse the print in a couple of ces of this, rock and turn over, empty the dish of solution, take other 2 ozs. and so on. Two or three such washings are usually ough to remove the stain.

The print is next washed in a gentle stream for about five minutes, turned over several times, and then drained, laid flat on the bottom of a dish, and the dark-room gas turned up. The print is held up to the gas for say half a minute at a distance of 1 ft., and the developer that was first used is again applied. If nothing is seen at the end of a minute, the developer is poured off into the graduate, the print exposed again to the gas flame, and the developer again applied.

For this second development plenty of time must be allowed as it is slower. Of course it is understood that the naked gas flame is kept alight all the time during the second development. But as soon as the negative image once starts to develop, it will probably not be necessary to pour off the developer and give any more exposure near the gas flame; the developer being practically colourless, the rocking of the dish in the room, with the ordinary gas flame burn- ing, will give enough light to urge on the image-formation. For the second development we must go on developing until the shadows of the picture, that is the light parts of the second negative, are just visible on the paper. When looking through the paper negative, we must bear in mind that we have the paper itself, as well as the negative image and silver to allow for.

For fixation I advise an acid fixing bath, as this helps to keep the paper clean and stainless. The following proportions are con- venient:—

Water .....	20 ozs.
Hypo .....	3 ozs.
Soda bi-sulphite (acid sulphite) ....	$\frac{1}{2}$ oz.

Let one of these negatives, after well washing and drying, be printed on bromide by contact. It will be found (1) that the paper negative requires about 1 min. exposure at 2 ft. as compared with 15 seconds at 4 ft. in the case of the glass original negative, a differ- ence of say 16 to 1. (2) It will be noticed that the second negative is reversed as regards right and left. Therefore, when we are making an enlarged negative (with enlarging lantern) and want our large negative to print the picture the same way round as the original little one, we must remember to put the small negative in the enlarger, with its glass side towards the bromide paper used for its enlarge- ment. Otherwise the procedure for the enlarged negative is exactly like that just described. The exposure of the enlargement must be sufficient to penetrate the densest parts of the negative, and develop- ment should be full with ample time allowed.

REV. F. C. LAMBERT, M.A., F.R.P.S.

## MAKING ENLARGED PAPER NEGATIVES FROM NEGATIVES.

The following method of making paper negatives direct from negatives is described in "Photo-Notes" for October. The process is very simple, and there is no very apparent reason why it should not be adapted to the production of a ready-toned positive enlargement from a lantern slide, or the production of duplicate negatives on glass. Possibly some slight modification of Mr. Morison's methods may be necessary in such cases, and a good deal will no doubt depend on the first exposure.]

ATTENTION has often been directed to the making of a negative from negative by printing and developing a positive, then dissolving

away the reduced silver image, exposing the remainder of the silver bromide to light and developing it. The new negative is thus built

up from the silver salts that in the ordinary process of making a positive are fixed out in the hypo bath. The following process is more or less the reverse of this one, and while perhaps not new is rather more easily carried out.

Various densities of negative can be secured by varying the first exposure. Generally from two to three times the exposure required for a good positive should be given. Proper time, however, varies somewhat with the paper employed.

The working instructions for paper negatives are as follows:—Exposure is made by contact or through the lantern, and the print is developed as far as it will go without fog. It is then rinsed in water and placed in a chrome alum bath, after which it is flooded with the usual sulphiding solution employed in sulphide toning until the action of the sulphide is complete. The paper must then be well washed free of all sulphide and the original developed image is then bleached out with any convenient bleacher, such as ferricyanide and bromide, and dissolved by a fixing bath of hypo.

The result is a finely graduated negative and the printing density is good owing to the colour of the deposit. This density can be regulated by the first exposure, during which also any local shading or the insertion of clouds can be effected. A long exposure gives a thin negative, and vice-versa.

Lantern slides can also be made by this process direct from lantern slides, and the resulting image is of course a toned one.

WILLIAM MORISON.

#### SIR BENJAMIN STONE ON PHOTOGRAPHY.

THE current issue of "M.A.P." presents in its series of autobiographical chapters, "In the Days of My Youth," Sir Benjamin Stone, M.P., who contributes an interesting account of his career as a collector and maker of photographs.

"My first collection of photographs," says Sir Benjamin, "was such as I could buy. The pictures were poor and small, but I contented myself with them until the time when I had to go to the middle of America and to South Africa, when I was compelled to make myself a photographer, for I could not get the pictures that I wanted, either for love or money. My collection now embraces records in every part of the world. It numbers something like 30,000 photographs, fully half of which are my own work. They are all catalogued and arranged in boxes according to the geographical positions they illustrate, so that I can refer to any of them at a moment's notice.

"While photography has been a hobby with me, I had very definite objects in view, and these induced me to pursue the course I have done. I should like to emphasise this point, and to say that in my opinion photography is the most perfect means we have of conveying any kind of knowledge in the easiest and most comprehensive manner. No description, however well written, will enable one to describe a given object at a glance. A photograph does this absolutely, and is at the same time the most perfect form of picture one can have, always provided, of course, it is made by a man who is skilful. It thus becomes an absolute record of the object which can be conveyed at once to the intelligence of people, who are made to realise the truth concerning that object. There are photographs, however, which are not truthful. Some of these are cinematograph pictures which are made up of untruthful elements, and therefore are not truthful. Something of the same character applies to the pictures which are printed in the daily papers. They are not only poor in their work, but inaccurate in that they convey the wrong idea. Others, however, are worse still, for they are manufactured pictures which are photographed in order to convey the idea that they have been taken on the spot. These are not only untrue, but are purely imaginative, and the attention of the House of Commons has actually been called to some of them. This happened in connection with a certain picture supposed to represent scenes which had occurred in Ireland.

"My first chief aim in photographing is to record history. My next is that, having provided these records of the best possible kind, they should be multiplied in a cheap form to be used in teaching in schools. In other words, that there should be a magic-lantern in every school in the land, to be used not merely for purposes of amusement, but for purposes of instruction. My third aim is that there

should be some central authority—a Government Department, in—which should provide sets of pictures to be supplied to the teachers for their classes in all the elementary schools in the country. I would have the Universities to distribute, from the central authority, technical subjects to teach history, like Assyrian history, for example, which should be placed by the side of the real objects in the museums, so that they might easily be compared. Next, I would have pictorial representations of every country to teach the child what those parts of the world were like, and, lastly, all the treasures in all our museums should be photographed, and photographed cheaply, to be exchanged with similar institutions all over the world. In this way the vast treasures which are not even known to us by hearsay would become available for exhibition to the pupils of all the schools, and could not help producing a salutary effect on their intelligence and taste."

#### AWARDS AT THE FRANCO-BRITISH EXHIBITION.

The following are the awards of the British exhibits in Class 11.—Photography: Materials, appliances, processes and products. Awards to French exhibits are not yet announced.

##### GROUP 3.—DIPLOMA FOR GRAND PRIZE.

British Pictorial Photography.	Senior, Edgar.
Oxford University Press.	Butler, Chas. P.
Ilford, Ltd.	Cambridge University.
Burroughs, Wellcome and Co.	Waterhouse, Major-General.
Dallmeyer, J. H., Ltd.	Watts, W. W.
Valentine and Sons (1907), Ltd.	Stoneyhurst College Observatory.
"Daily Mirror."	
Public Works Department (Sydney).	Jones, Chapman.
Government, South Australia (Australia).	Lockyer, W. S.
Government, New Zealand (New Zealand).	Stead, J. E.
Lafayette, Ltd.	National Physical Laboratory.
McClellan, W. M.	Tarrant, Kenneth J.
Hartley, Prof. W. M.	Cornish, Vaughan.
	Mauder, Mrs.
	Solar Physics Observatory.
	Beilby, G. J.

##### DIPLOMA FOR GOLD MEDAL.

Savory, E. W., Ltd.	Macnaughten, Mrs. Ellen.
Greenham and Evans (Australia).	Poulsen, P. (Australia).
Schmidt Studios (New Zealand).	McGann, Terence (Australia).
Beattie, Mr. (Hobart, Tasmania).	Le Faivre (Fiji, Colonies).
Guggisberg, Major J. G., R.E., C.M.G.	Lawrence, Captain (Colonies).

##### DIPLOMA FOR SILVER MEDAL.

Kinora, Ltd.	Brown, E. Styant.
--------------	-------------------

##### DIPLOMA FOR BRONZE MEDAL.

Gray, John.	Gentil, J. G.
Rehaut, G.	

In Class 11.—Typography and drawings reduced by mechanical or photographic processes—diplomas for grand prize are awarded to Bemrose and Sons, Ltd., Carl Hentschel, Ltd., Valentine and Sons (1907), Ltd., and others.

PHOTOGRAPHS OF THE FRANCO-BRITISH EXHIBITION.—An exhibition of photographs of the exhibition or of photographic work done in the exhibition grounds will be held in the Congress Hall, October 27 to 31. The exhibits will be divided into the following classes of architecture, figure studies (prints) and lantern slides (any subjects). Gold silver and bronze medals will be awarded in each class, and there are also supplementary prizes offered by the Kodak Co. for the best photographs taken with a Kodak, and Messrs. Ilford, Ltd., for the best photograph on Ilford plates and papers. All prints should be sent in by October 23, addressed to the Secretary, Photo-Competition, Franco-British Exhibition, London W.

## Exhibitions.

### ROTHERHAM PHOTOGRAPHIC SOCIETY.

THE Rotherham Exhibition, promoted by this local society, has been held during the past week (October 14 to 17), and has received liberal support from exhibitors, and a large share of patronage from the townspeople. With a persistency which has had the best results, the promoters have gone forward until the effort is regarded as one of the features of the year. It was the nineteenth annual appeal, and in various directions indicated growing interest. In the open section there were 188 exhibits, the most attractive class being landscape, with the others well up in numbers. A section of colour work received fifteen entries. Members made a much braver display, and particularly in still life and flower and fruit studies good advancement was noticeable. Messrs. Dallmeyer lent their series of American portraits; the Rotary Photographic Co., examples of colour work; and Messrs. Lumière and Captain W. J. Stomm, Harrow-on-the-Hill, Autochromes. A department of much interest was a loan collection of transparencies by members. The opening ceremony was performed by Miss Mary L. Egerton, of York (a former member of the society), Mr. C. H. Moss, J.P. (president), presiding. The company, which was a large one, included the Mayor and Mayoress (Dr. and Mrs. Lodge). This ceremony was followed by afternoon tea at the invitation of the Ladies' Committee. Each evening there were animated pictures and prize lantern slides, and a musical programme. Messrs. C. Barrow Keene, F.R.P.S., and T. A. Scotton, of Derby, were the judges. Their awards were as under:—

#### OPEN SECTION (AMATEUR OR PROFESSIONAL).

Class A—Landscape, Seascape, and River Scenery—Bronze Plaque.—"A Sussex Cottage," C. H. Hewitt, London; "Shields' Harbour," John Walton, Sunderland; "Sunlit," Edwin Marks, Stoke-on-Trent; "A Landscape," James W. Gallimore, Sheffield. Hon. Mention.—"Near Brockhurst," C. H. Hewitt, London; "A Peaceful Evening," Francis A. Tinker, Sheffield.

Class B—Portraiture, Figure Studies, and Animals—Bronze Plaque.—"Chaffinches," George A. Booth, Preston; "A Study," Joseph Bell, Sunderland; "The Captain," B. B. Mewburn, Sunderland. Hon. Mention.—"Portrait," R. M. Vaughan Evans, London; "The Village Blacksmith," James A. Martin, Loughborough; "A Stranger in the Village," Norman Blake, Bedford.

Class C—Architecture—Bronze Plaque.—"Through an Ancient Gateway," F. C. Boyes, Ilford; "A Flood of Sunshine," Alfred Roffey, Birmingham. Hon. Mention.—"Morning Light, Wells Cathedral," John Dunlop, Motherwell.

Class D—Flowers, Fruit, and Still Life—Bronze Plaque.—"Pinks," Mrs. S. S. Laurence, Wembley, Middlesex; "Gooseberries," Geo. A. Booth, Preston. Hon. Mention.—"Lily of the Valley," W. T. Hebburn, Hamilton, N.; "Eggs," John Maddison, Middlesbrough; "Fungi," A. E. Peck, Rotherham.

Class E—Photographs in Colours (Autochrome or other colour transparencies included)—Bronze Plaque.—"A Group of Cupids" (from the original painting by Boucher), Captain W. J. Stomm, Harrow-on-the-Hill; "Oranges and Bananas," Eric W. G. Burden, Loughborough. Second Bronze Plaque.—"Strawberries," G. and D. Smith, Sheffield.

Class F—Lantern Slides. Sets of four. (Autochrome or other colour transparencies excepted).—Bronze Plaque.—Francis A. Tinker, Sheffield; Richard Hancock, Stechford; Alfred Taylor, Whalley, Lancashire.

#### MEMBERS' SECTION.

Class G—Landscape, Seascape, and River Scenery—Bronze Plaque.—"In a Derbyshire Dale," F. G. Blackshaw (1); "Leafy June," F. A. Jordan (2). Hon. Mention.—"Lynmouth," F. W. Crookes; "A Hive of Industry," F. A. Jordan.

Class H—Portraiture, Figure Studies, and Animals—Bronze Plaque.—"Skilled Work," G. W. Gulliver (1); "A Pensive Maiden," W. C. Briggs (2). Hon. Mention.—"A Cat Study," F. W. Thomlinson.

Class I—Architecture—Bronze Plaque.—"Here they Dwell no Longer," W. Firth (1); "Doorway," Ely, A. E. Rawson (2). Hon. Mention.—"From the South Choir Aisle," Ely, A. E. Rawson.

Class J—Flowers, Fruit, Still Life, and Miscellaneous—Bronze Plaque.—"A Study," F. G. Blackshaw (1); "There's Pleasure in Crime," W. C. Briggs (2).

Class K—Lantern Slides (sets of four)—Bronze Plaque.—Ralph Chislett (1).

Class L—Board of Exhibits—Bronze Plaque.—H. Rushforth (1); A. E. Peck (1). Hon. Mention.—A. S. Pye; G. Froggatt.

### FORTHCOMING EXHIBITIONS.

September 11 to October 24.—Photographic Salon. Sec., Reginald Craigie, 5A, Pall Mall East, London, S.W.

September 17 to October 24.—Royal Photographic Society. Sec., J. McIntosh, 66, Russell Square, London, W.C.

October 22 to 26.—Hove Camera Club. Sec., W. Chater Lea, Cransley Lodge, Dyke Road Avenue, Brighton.

October 27 to 31.—Heaton and District Camera Club. Secretary, George C. Urwin, 24, Tenth Avenue, Heaton, Newcastle-on-Tyne.

October 28 to 29.—Watford Camera Club. Sec., W. Branch, 100, High Street, Watford.

November 2 to 11.—Portsmouth Camera Club. Entries close October 24. Sec., F. J. Lawton, 20, Clarence Square, Gosport.

November 4 to 7.—Hackney Photographic Society. Secretary, Walter Selfe, 70, Paragon Road, Hackney, N.E.

November 11 to 14.—Cambridge and District Photographic Club. Entries close October 29. Sec., T. J. Sowdon, Sunny Side, Guest Road, Cambridge.

November 20.—Redhill and District Camera Club. Entries close November 7. Sec., J. Paterson, Ness House, Redhill.

November 23 to 26.—Lancaster Photographic Society. Sec., J. Holt, 11, Fern Bank, Lancaster.

December, 1908, to January, 1909.—Kiew International Photographic Sec., S. T. Horovitz, Technical Society, Kreshtchatik, 10, Kiew, Russia.

1909.

January 6 to 27.—Northern Photographic (Manchester). Entries close December 11, 1908. Sec., S. L. Coulthurst, Broad Oak Road, Worsley, Manchester.

February 13 to March 13.—South London Photographic Society. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been received between October 5 and October 10:—

COLOUR PLATES.—No. 20,971. Improvements in or relating to the manufacture of colour plates or screens for colour photography. Jens Herman Christensen, 111, Hatton Garden, London.

PROJECTION LANTERN.—No. 20,069. Insulated projection lantern. Charles Marshall Lungren, 52, Chancery Lane, London.

COLOUR SCREENS.—No. 21,097. Improvements in or relating to the manufacture of colour screens or plates for photography. Jens Herman Christensen, 111, Hatton Garden, London.

CINEMATOGRAPHS.—No. 21,098. Improvements in or relating to cinematographs and like apparatus. Benjamin Jumeaux, 111, Hatton Garden, London.

CONTINUOUS PHOTOGRAPHS.—No. 21,186. System for taking continuous photographs for panoramas, cinematographs, and for circular ordinary or stereoscopic photographs. Auguste Saunier, 116, High Holborn, London.

BACKGROUND SUPPORT.—No. 21,245. Improved support for optical

lantern screens and photographic backgrounds. Frank van Neck, 1, Cursitor Street, Chancery Lane, London.

TRIMMING APPARATUS.—No. 21,266. Improvements in apparatus in cutting or trimming photographic and drawing papers, and other thin materials or substances. John Merritt, 36, Chancery Lane, London.

CINEMATOPHGRAPHS.—No. 21,308. Improvements in or in connection with light cut-offs for cinematographs and the like apparatus. John William Harris, 30, Park Row, Leeds.

OPTICAL LANTERNS.—No. 21,328. Improvements in optical lanterns for enlarging and the like. William Pollock, 121, West George Street, Glasgow.

SLIDE CARRIERS.—No. 21,422. Improvements in slide carriers for optical lanterns. Walter Joseph Coles, 27, Bass Street, Derby.

CINEMATOPHGRAPHS.—No. 21,495. Improvements in and relating to disc cinematographs and talking machines. Ferdinand von Madaler, 18, Southampton Buildings, London.

#### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

PRINTING FROM WET NEGATIVES.—No. 22,244. 1907. Protection is claimed for the method of laying a sheet of transparent celluloid upon a negative in order to print from it while in a wet state. After use the celluloid may be stripped off and used again, but if preferred it may be left on the film, in which case it will protect the film. Reference is made by the inventor to Specifications to Letters Patent, Nos. 24,750\*, of 1898, 25,942 and 28,793, of 1902, and 1,367, of 1877. Spence Lees, 57, Portman Road, Wavertree, Liverpool.

FOCUSING ADJUSTMENTS.—No. 11,835. 1908. For moving the focussing slide on the base board of a camera hitherto a single or double rack gear has been used. Apart from the increase in cost of making the camera, this gearing has the disadvantage of requiring a special device for fixing it in position, which was felt to be very troublesome, especially when taking photographs in winter and during tours on high mountains, where the work has to be done with chilled

and stiff hands. The invention consists in a novel device for adjusting the focussing slide without rack and wheel gearing. In the drawing a form of construction of the device is represented for a camera with two lengths of focus. For a single length of focus naturally only one side of the adjusting device is required.

In the base board *a* of a photographic camera a screw spindle *b*, which is represented on the drawing by dotted lines only, has its bearings. A small knob *c* serves for turning this spindle. Above the spindle a transverse slot is formed in the slideway, in which slot a nut *d* on the spindle can travel. The objective lens or the focussing screen itself is carried in the known manner on a slide *e*, and fixed according to the length of focus of the lens. In this slide *e* an inclined slot *f* is cut, through which a flat-headed pin on the nut *d* passes. If the knob *c* is turned in one or the other direction, the nut *d* is moved to and fro, and the slide *e* pushed forward or backward thereby.

When using the apparatus with two lengths of focus the slide *e* is drawn out for the longer distance, during which the flat-headed pin of the nut slides in a longitudinal slot until it arrives at the second inclined slot *h*. By turning the knob *c* in the reverse way, the setting of the focussing slide is again effected.

Naturally, only one inclined slot is required if the device is to be used only for one length of focus of the lens. The form of the slot is optional, it may be either straight or variously curved, according to the special object aimed at. Emil Wünsche, Actiengesellschaft für Photographische Industrie, Reik, near Dresden.

The following complete specification, etc., is open to public inspection, before acceptance, under the Patents Act, 1901:—

COLOUR SCREENS.—No. 20,909. Method of making polychrome screens for colour photography. Brasseur.

### New Trade Names.

WINGED SHIP (device).—No. 302,236. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives. Paul Ruben, 56, Leadenhall Street, London, E.C., general merchant. April 13, 1908.

## Analecta.

Extracts from our English weekly and monthly contemporaries.

### Two Tones on the same Gaslight or Bromide Print.

The first operation (says a writer in "Photography and Focus" for October 20) is the production of the postcard, which is carried out in the usual way, the card being properly fixed and washed, and then allowed to get thoroughly dry. While the card is drying the necessary materials for the after operation may be got together. These consist of the toning bath, which may be of any of the recognised formulæ, copper, uranium, iron, etc., a small pot of vaseline, and the mask through which the "picture" portion of the card was printed. The card is laid face upwards upon a clean surface, and the mask is adjusted so that the view or portrait appears through the opening. The finger is then dipped in the vaseline, and this is lightly smeared over the picture, care being taken not to shift the mask. When the smearing process is complete the card is lifted by the edges and is placed in the toning-bath, which will, of course, be repelled by the vaseline, and will operate only on the border portion of the postcard, leaving the picture portion in its original condition. As soon as the toning operation is finished, the necessary washing is carried out in the usual way, and the card is once more dried. It only remains to remove the vaseline. Most can be wiped off with a soft duster, but if this is not sufficient for the purpose the print can be finished off by placing over it a piece of clean blotting-paper and pressing it down with a hot iron. This will be found to absorb the last traces of the vaseline. If it is the view that is to be toned, the border being left untuned, it is, of course, the blank which was left when the mask was cut that must be placed over the card, the vaseline being then smeared over the border. The great thing is to be careful that the whole area to be protected receives the coating of vaseline, and that none gets on the part that is to be toned, or patchy results will be inevitable.

## New Apparatus, &c.

**A NON-IRRITANT TRIPOD SCREW.**—How many times has one wished for a tripod screw that one could insert into the camera board while the latter could be held up to the light of day, and then effect the attachment to the tripod head. Instead, one has had to fumble with the tripod screw under the top until a propitious moment arrived when the bush in the camera coincided with the aperture in the tripod

head. However, the firm of Mr. James H. Sinclair, of 54, Haymarket, W., has now issued a tripod screw which is so made that it can be first attached to the free camera, and the latter then placed upon the tripod and made fast with the fly-nut supplied with the screw. The screw allows of the camera being moved in the usual way on the tripod head, and is constructed in such a way that it will go into the camera only a sufficient distance to hold it. It is made

of quarter-inch Whitworth thread, suitable for nearly all British and American cameras, at the price of 1s., and should be a boon to the hand-camera worker. Mr. Sinclair might well bring out a stronger pattern for large cameras, whole-plate and over, which are rarely provided with a turntable head on account of the difficulty experienced in erecting such weighty instruments on a tripod secured to the camera one leg at a time.

**A STUDIO COMBINED TABLE AND SEAT.**—A studio accessory which very excellently serves two purposes is sold by Messrs. Houghtons

under the name of the "Carved Oak Monk's Bench." It serves as a table or bench, as shown in the drawing, but the table-top

swings back, forming a seat. The lid of base lifts up, and a handy box is thus provided. The accessory measures 2ft. 6in. in length, is 1ft. 3in. deep, and stands 3ft. 3in. high. The price is £2 12s. 6d.

**PLATE-MARKING POSTCARDS.**—A very simple and inexpensive attachment for the impression of a plate-mark on postcards is submitted to us by the firm of J. Billcliff, Richmond Street, Boundary Lane, Manchester, S.W. It consists of a die and template, each mounted in wood, and fitting within each other in such a way as to provide for the insertion of the postcard. The attachment is sold at 2s., and is intended to be worked by hand pressure, though it can be used in any press, such as a dry-mount. The apparatus works very effectively, and produces a strong impression. Messrs. Billcliff supply a screw press at 7s. and a lever press at 10s. 6d.

## New Materials, &c.

**"CAMEO" CHRISTMAS MOUNTS.**—The Tress Co. issue under this title a series of mounts of the slip-in pattern in dark green or brown, with gold lettering and an embossed profile of a head on the front cover. The mounts are of very tasteful appearance, and are sold at 4s. 11d. or 6s. 11d. per 100, according to size.

**TINTO BOARD MOUNTS.**—Under this name a novelty in mounting boards has been placed upon the market by Messrs. J. and W. Mitchell, Bordesley Paper Works, Birmingham, in the shape of a mounting paper which is differently coloured on its two sides. This duplex character is given to it with a nice regard for the requirements of the amateur photographer, the choice of tints being among those of quiet and unpronounced colour. The tints run in browns and greens, and the new mounting boards are put up in sizes from 5 x 6½ in. for quarter-plate prints to 7½ x 9½ in. for half-plate prints, in shilling packets; or they may be obtained in sheets up to 22 x 32 in. in size. Messrs. Griffins and Messrs. Kodak, Ltd., are agents for the supply of the boards.

**MOUNT STRUTS.**—A new line with the Tress Co., 4, Rathbone Place, is a strut which can be attached to any mount in order to permit of the latter being stood up on a table or in a window or showcase display. The strut is supplied all ready gummed, so that it is only necessary to moisten it and affix it to the mount. The price of these useful accessories is sixpence per dozen.

**DISPLAY OF SPECIMENS.**—The Tress Co., of 4, Rathbone Place, W., have added to the many specialties of theirs for the professional photographer that of mounting and displaying a set of specimen prints supplied to them for the purpose. The prints may be from six upwards in number, and are mounted by the Tress Co. with decoration of an appropriate character. The work is one which a photographer often feels himself unable to perform with success, although such work, intended as it usually is for display in show-cases and similar positions, is of great importance.

**"LINGRAIN" BROMIDE PAPER.**—A bromide paper with a surface which is something distinctive despite the almost innumerable brands of paper on the market is supplied by Messrs. John J. Griffin and Sons under this name. The paper has a surface resembling that of a very fine linen, with the result that while it gives a commendable softness of outline, the effect is not sufficiently pronounced to destroy the detail in the picture. We find "Lingrain" to be in other respects a bromide paper which gives excellent results with amidol and metol-hydroquinone developers, and also tones well by the sulphide process. It is sold at a price based on twelve half-plate pieces for 1s.

**EASTMAN PLATE COMPETITION (£240 IN PRIZES).**—Kodak, Ltd., announce that, in deference to the wishes of many intending competitors, prints for the third section of the competition will be received up to Monday, November 16, instead of October 20, as provided in the prospectus. Full particulars can be obtained from Kodak, Ltd., 57-61, Clerkenwell Road, London, E.C.

## CATALOGUES AND TRADE NOTICES.

**SECOND-HAND APPARATUS.**—A 56-page list of apparatus shop-soiled and guaranteed to be as described has just been issued by the Westminster Photographic Exchange, Ltd., 119, Victoria Street, London, S.W. It gives particulars of a great variety of hand and field cameras, lenses, enlarging shutters, and sundries, a total of more than 700 different lots, which are offered at substantial reductions on the "new" price. The list includes many excellent bargains, and the Westminster Exchange makes a very fair offer as to sending on approval.

**ARC LAMPS.**—A catalogue of arc lamps for portrait and process photography has been issued by the Electrical Co., Ltd., 121-125, Charing Cross Road, London, W.C. This firm supplies both open and enclosed arcs and the necessary electrical accessories.

**THE PRISM.**—The current number of this little magazine (sent for one penny stamp by Messrs. A. E. Staley and Co., 19, Thavies Inn, London, E.C.) deals with the manufacture of the microscope.

**THE PRIMUS LANTERNIST'S POCKET-BOOK AND DIARY.**—The 1908-9 edition of this useful pocket-book, edited by Mr. W. F. Butcher, is issued as before at 6d., and contains data as to electric and other lights, including description of the current obtainable in the chief provincial towns, a diary of engagements, and directory of dealers in lantern apparatus, with also an abridged price list of Messrs. Butcher's leading lantern apparatus.

**CRITERION PAPERS.**—A new list has been issued by the Birmingham Photographic Co., Ltd., Stechford, Birmingham, giving the full prices of their manufactures and including the "Nonstress" gaslight and bromide papers. The list is sent free on application.

## Meetings of Societies.

## MEETINGS OF SOCIETIES FOR NEXT WEEK.

## FRIDAY, OCTOBER 23.

Aberdeen Photo Art Club. "Bromoll and Rawlins' Oil Process." W. L. Dunn.  
 Ilkeston Arts Club. "On the Printing, Developing and Toning of Velox Papers." W. F. Slater.  
 Sutton Photographic Club. Annual General Meeting.

## SUNDAY, OCTOBER 25.

South London Photographic Society. Excursion to Epping Forest. G. Brown.

## MONDAY, OCTOBER 26.

Cripplegate Photographic Society. "Exposure for the Subject." C. W. Coe.  
 Bourneville and District Photographic Society. "On the Printing, Developing and Toning of Velox Papers." W. F. Slater.  
 South London Photographic Society. "P.O.P. Toning and Finishing." E. W. Taylor.  
 Southampton Camera Club. "Afar in the Fatherland." W. L. F. Wastell.  
 Bradford Photographic Society. "Some Photographic Attempts to Get Out of the Beaten Track." A. Houghton.

## TUESDAY, OCTOBER 27.

Bootle Photographic Society. "On the Printing, Developing and Toning of Velox Papers." W. F. Slater.  
 Manchester Amateur Photographic Society. Lantern Slide Testing Night.  
 Hackney Photographic Society. "Westminster Abbey and its Place in English History." A. H. Hester.  
 Birmingham Photographic Society. "Some Picturesque Midland and Cotswold Villages." W. A. Clark.  
 Kinning Park Camera Club, Govan. "Cycle, Camp, and Camera." Robert Gracie.  
 Leeds Photographic Society. "The Fringe of the Austrian Alps." C. B. Howitt.

## WEDNESDAY, OCTOBER 28.

Everton Camera Club. "On the Printing, Developing and Toning of Velox Papers." W. F. Slater.  
 North Middlesex Photographic Society. "An 'Autochrome' Tour, Torquay and District." A. J. Woodway.  
 Wimbledon Park Photographic Society. "Defects and their Remedies in the Negative and Print." W. J. Randall.  
 Croydon Camera Club. "Toning Bromide Prints." H. W. Bennett.  
 South Suburban Photographic Society. "Yesterday and To-day in Photography." E. G. Price.  
 Leeds Camera Club. "How to Make a Bromide Enlargement with an Ordinary Lantern." H. Crossley.  
 Edinburgh Photographic Society. "Development." T. Drummond Shiels.  
 Borough Polytechnic Society. Summer Outings' Print Competition.

## THURSDAY, OCTOBER 29.

New Mills Camera Club. "On the Printing, Developing and Toning of Velox Papers." W. F. Slater.  
 Richmond Camera Club. Paper by F. P. Cembrano, F.R.P.S.

Melbourne (London) Camera Club. "The Choice and Use of Apparatus, with Short Treatise on Lenses." The President.  
 Rugby Photographic Society. "How to Make and Manipulate an Enlargement." G. B. Morgan.  
 Blackburn and District Camera Club. Whist Drive and Dance.  
 Liverpool Amateur Photographic Association. "By Battlement, Wall, and Tower." James Shaw.  
 Redley, Farsley, Calverley, and Bramley Photographic Society. "Large Pictures from Small Negatives." H. Crossley.  
 Handsworth Photographic Society. "The Naturalist and his Camera." Herbert Thompson.  
 Chelsea Photographic Society. "Ozobroma." T. Manly.

**LEEDS PHOTOGRAPHIC SOCIETY.**—The opening meeting of the session was held at the Leeds Institute (the new quarters of the society) Cookridge Street, on October 13, and took the form of a social evening and exhibition of members' work. Ninety-one prints were sent for exhibition, contributed by the following members:—Miss Edith M. Scholes, Messrs. Banks, Denham, Fielding, Edwards, Jackson, Mackay, Morfitt, Rodwell, and Walker. Mr. J. H. Gash showed a splendid selection of Autochrome photographs, which were well displayed and greatly admired, as were also a collection of prints from "The Guild" and a small loan collection by the members of the Leeds Camera Club. Coffee was served during the evening, and a really splendid programme of music was contributed by Miss Florence Carter, Mr. Arthur Wheelhouse, and Mr. E. P. Stead. Miss Carter possesses a contralto voice of very fine quality, and her highly cultivated style and the beautiful rendering of the songs "Beloved, it is Morn" (Aylward) and "Good-bye" (Tosti), were much appreciated. The programme concluded with an exhibition of lantern slides by Mr. J. Allen and Mr. Godfrey Bingley. The usual votes of thanks brought to an end one of the most enjoyable evenings in the annals of the society.

**EDINBURGH PHOTOGRAPHIC SOCIETY.**—The forty-ninth session of the society has opened promisingly. The rooms in Castle Street have been re-decorated in a most pleasing manner, and are now admirably suited for pictorial exhibitions, as well as for supplying the other wants of the large membership, which amounts to nearly four hundred. A syllabus of more than ordinary interest has been prepared for the session by the energetic hon. secretary, Mr. J. S. McCulloch, W.S., and informal meetings for the discussion of difficulties and for practical demonstrations are to be a prominent feature of the winter work. The president's opening address was given on October 13 by Mr. J. F. Duthie on "High-Speed Photography." Many beautiful examples were shown by lantern, and enlargements from small negatives of moving objects were exhibited. Mr. Duthie spoke of a large aperture lens and a focal-plane shutter as being almost indispensable and he favoured the reflex camera as being the best for high-speed work. While admitting that time development was convenient and reliable, Mr. Duthie advocated individual treatment of negatives as giving the best results. An interesting discussion followed the reading of the paper.

**FLASHLIGHT PHOTOGRAPHY.**—Lecturing to some forty members the South Suburban Photographic Society at Plough Hall, Lewisham, on Wednesday evening, the president (Mr. F. J. Mortimer, F.R.P.S.) expressed surprise at the unnatural results obtained by the professional photographer when he took a stage photograph, and said he should like to have an opportunity of trying whether it was possible to get in a photograph the exact effect which one sees from the front row in the pit. The professional, he guessed, from the stage pictures published in the illustrated papers, disposed his flashlight so as to give top and side lighting, as if he were taking an ordinary interior. He forgot that the stage, as we see it from the front, is lighted from the footlights and from the wings. To secure a natural effect then the photographer should dispose his flashlights at the footlights and in the wings, so as to give the same lighting as that we ordinarily see from the auditorium. By means of diagram lantern slides, and apparatus, he explained and illustrated the whole mystery of obtaining soft results in flashlight photography, and avoiding the harsh soot-and-whitewash appearance of the flashlight photograph one so often sees, and he offered a prize for the best flashlight photograph in a competition, to be judged at the end of the session.

**CROYDON CAMERA CLUB.**—Mr. A. C. Braham, F.R.P.S., of the Autotype Company, an old friend at Croydon, gave a demonstration of the carbon process last week. There was little new to chronicle.

but a process which may almost be regarded as having reached state of splendid finality, but the string of questions which the lecturer encountered bore testimony to the interest evinced. At onset some amusement was caused by the suicide of a small colony of ants in the cold-water tank. Mr. Braham objected to his presence, and whilst fishing them out one by one somewhat suspiciously enquired how they had got in. "You must blame the lecturer company," said a member. "I shall do nothing of the sort," retorted the lecturer, "and, moreover," he added, glancing reflectively at the many signs of liquid sustenance around him, "I do not regard any member of this club as an authority on water gardening." This was a case of "the pot calling the kettle black" with a vengeance, for with delightful irony Mr. Braham was holding a "bibulous board" in his hand at the time, and must have been aware that the many fine Autotype pictures scattered about rested purely by suction.

In answer to a question, the lecturer said that the appearance of backing paper when stripped was no indication of correctness of exposure, though many thought it was. It seemed a pity that the backing-papers, with their oozing pigment attached, were in cases thrown away. Several of these showed distinct signs of a future which in these days of "salon impressionism" might usefully have been spared. Irrespective of qualities open to debate, there was sufficient diffusion of image, together with a sort of automatic originality of treatment, which should appeal strongly to modern combined judge and exhibitor. Replying to another question as to the alleged necessity for collodionising the tissue when making transparencies on substratumed glass—an operation which most amateurs fight shy of—Mr. Braham said its adoption was not compulsory years ago if fine details in the high-lights were to be preserved and reticulation of the film avoided. The present Autotype tissues, however, worked well without it, and failure would rarely be met with, owing to its omission. Among the many useful "tips" furnished was one to the effect that if the tissue is dry or somewhat horny perfect contact might be secured between it and the negative by the simple expedient of warming the paper pad. This should invariably be done with large prints.

## Commercial & Legal Intelligence.

**INLAND REVENUE PROSECUTION OF THE "FREE-ENLARGEMENT" VASSER.**—At the Worcester County Petty Sessions last week (Friday) Brown, 21, Clarence Gardens, Clarence Road, Lower Clapton, London, was charged with trading without a hawkers' licence at the sale of enlarged photographs. Mr. Shaw prosecuted for the Inland Revenue. He said defendant and four other men took up their residence at Bedwardine House, St. John's, for about two months. The procedure adopted by them was that one man travelled round, calling upon publicans and other persons, showing to them an enlargement of a photograph, and offering to execute, free of charge, a similar enlargement of a photograph, which could be hung up as a sort of advertisement. Then, a second person (in this case the defendant) called with the enlarged photograph and some specimens of moulding for frames, and the person who desired the enlarged photograph was then told that he must purchase a frame before he could have the photograph. The first person took any objection, and said he was told he could have the enlargement free, he was told that he must have made a mistake. In most cases the persons desiring the photograph selected a moulding and bought a frame. Of course, added the advocate, the price of the frame was amply sufficient to pay for the photograph.

Mr. Shaw, referring to the legal aspect, said defendant had refused to take out a licence. The case clearly came within the definition of the Act. Defendant travelled with a horse and trap, and carried specimens of moulding. There were certain exemptions under the Act, but none of these applied to defendant's case. Mr. G. F. Bradley, Inland Revenue officer, said that he saw defendant hawking enlarged photographs at the New Inn, Sinton Green. Defendant had an enlarged photograph of Mr. John Evans' daughter, and offered to do another

on Mr. Evans paying for a frame. Mr. Evans, in his evidence, said he paid £1 15s. 6d. in all for the two photographs and frame. Defendant, who did not appear, was fined £1 1s. and costs, £3 12s. 6d. in all.

**A FOLKESTONE BANKRUPTCY.**—Under a failure of Benjamin Knight, of Fairmeade, Lyminge, carrying on business as a photographer, at Ben's Studio, 58, High Street, Folkestone, under the name of "Ben's Studio" (formerly of Dover), the Official Receiver has issued a statement showing the indebtedness to be £219 16s. 9d. and the deficiency £212 17s. 11d. The causes of failure, as stated by the debtor, are bad trade, competition, and ill-health. The Official Receiver's observations are as follows: The debtor (aged 21 years) was compelled to file his petition owing to pressure by creditors. He first started in business in October, 1905, as a photographer, in Biggin Street, Dover, with a free capital of £25. In the following February he opened a branch business at 46, Tontine Street, Folkestone, where he attended daily at certain hours. He contends he was doing fairly well, and towards the end of 1906 he removed from Biggin Street to larger premises—namely, 4, Snargate Street, Dover. Subsequently he found that having to work the Dover and the Folkestone businesses was more than he could manage, and a year ago he disposed of the Dover business for £68, out of which he paid the rent, rates, and taxes and local creditors. He then devoted the whole of his attention to the Folkestone business, which he continued at 58, High Street, Folkestone, having formerly given up the rooms in Tontine Street. He states that when he left Dover he was over £100 in debt, but continued to trade hoping to recover his position. He admits he discovered his insolvency about a year ago, and although he alleges his deficiency at that time was only small (as shown by the above deficiency account), by continuing to trade his affairs have become more involved, so much so that in February this year practically the whole of his furniture and effects were seized and sold under an execution. Since that time, he alleges, he has done a little work, a camera being lent to him. The debtor has not kept any cash-book or an accurate record of his receipts and payments. Of the 30 unsecured debts, seven, amounting together to £162 17s. 7d., exceed in amount £10 each, including a loan by a friend of £35 17s. 6d. All the debts appear to be for trade and domestic purposes contracted during the last three years. This bankruptcy has no connection with the business now conducted under different proprietorship at 4, Snargate Street, Dover.

**THE UNITED ARTISTS' GUILD.**—At the Maidenhead County Court, on October 14, Mrs. Ethel Mary Williams sought to recover 14s. 6d. from the United Artists' Guild, a London company. The action was not defended, and there was not a representative of the Guild present. Mr. J. E. Mason appeared for the plaintiff, and at the outset he stated that it was a case in which the money was paid under a misrepresentation of facts. A representative of the firm brought the picture to him on Tuesday, but he refused to accept delivery of it. Plaintiff stated that on August 10 last a lady agent of the firm called upon her and asked her if she would care to have an enlargement of her portrait, her husband's, or that of any other member of the family. She told her she could not afford it. "Oh," said the agent, "it's not a case of afford; it is simply to advertise our work." After some persuasion, she handed the lady a photograph of her husband, and she left. Some days later a man called and said that there was 14s. 6d. to pay, and that when this was paid the enlargement would be sent on. Plaintiff was dumbfounded, and told him she understood from the lady who first called that there was nothing to pay. "You knew different," the man replied, rudely. "Why did you take notice of that girl? She was for getting custom." Proceeding, plaintiff said that she asked the man to call again, as she had no money and her husband was not at home. He said he could not be bothered with that; he must have the money there and then, or he would "County Court" her. Being frightened, she borrowed the money from her lodger and gave the man the money. She had not received the enlargement.

Mr. Mason said the same thing had happened in several houses in the neighbourhood. The case, he added, amounted to one of duress.

His Honour said it was quite clear that Mrs. Williams was induced to pay because she was frightened by the demeanour of the man, and from her evidence it seemed that she was entrapped into paying

by something in the nature of a threat. He was surprised that if the claim was a genuine one there should be no one there to represent the company. He ordered the return of the money, with costs against the company, payment to be made forthwith.

We are glad to see that a local photographer, Mr. H. Southgate, of Station Road, Maidenhead, has taken the opportunity of drawing attention to this case. He has issued a circular, reprinting the above particulars and adding the paragraph:—

"There are several reliable photographers in the town of Maidenhead who are always ready to supply first-class enlargements which, both in quality and price, will compare favourably with those offered by outside canvassing firms. It will be to your interest to place your orders with local professional photographers, who pay the local rates and taxes, and on whose honourable and straightforward dealing you may safely rely."

Mr. Southgate informs us that he is agreeable to supply copies of the complete circular at cost price to other photographers who may be desirous of using it as an exposé of the "free portrait" fraud.

#### NEW COMPANIES.

**SCREENLESS PHOTO-ETCHING, LIMITED.**—Registered September 30. Capital £10,000, in 9,900 ordinary shares of £1 each and 2,000 deferred shares of 1s. each. Objects: To carry on the business of printers, publishers, photo-etchers, etc. Minimum cash subscription, 20 ordinary shares. Registered office, 5, Henrietta Street, Covent Garden, W.C.

Devillaine, of Grenoble, France, and to carry on the business of photographic film or plate manufacturers, manufacturers of cameras and other photographic apparatus, etc. Private company.

## News and Notes.

**GUIDE BOOKS TO WINTER RESORTS.**—Those about to select a seaside town in which to pass the winter months may be glad to know that a postcard sent to the Town Clerks of Bournemouth and Falmouth will bring them, post free, an illustrated booklet, giving particulars of these two favourite winter resorts. The little books, which are edited by Mr. George W. May, and published by the Health Resorts Association, 29, John Street, Bedford Row, London, W.C., contain a large amount of information in a small space, and are worth a careful perusal.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—Thursday, October 29, is to be a ladies' night at the L. and P. On this occasion Mr. A. H. Blake will lecture on "London in the Eighteenth Century."

**THE SALON SMOKER.**—Mr. Reginald Craigie writes us that the members of the Linked Ring much regret that, owing to the large amount of space occupied by the apparatus for the display of the colour photographs in the gallery, it has not been found practicable to hold the usual Salon smoker this year.

**THE DUNCAN RESEARCH LABORATORY.**—Mr. F. Martin-Duncan, F.R.P.S., whose photographic work in photo-micrography and cinematography and colour photography has been so successfully applied to educational and natural history purposes, has, we learn, established a laboratory for research work, which is to be fully equipped for the production of photo-micrographs, biological and natural history photography, photography in natural colours by the Autochrome and

trichromatic processes, and for all work in connection with the various applications of photography to science.

The photo-micrographic department is equipped with the latest and most perfect apparatus for the production of high-class photo-micrographs. Every care is taken of all microscopical preparations sent to the laboratory, and that the best possible photographic record of the preparations are obtained. A special feature is made of the photographing of serial sections and of serial photographs, to demonstrate growth, change of form, etc.

For the convenience of private practitioners, hospital X-ray departments, etc., Mr. Duncan will make a specialty of the developing of X-ray negatives and printing therefrom. He will give expert advice on the most suitable plates and apparatus for X-ray work. Those needing expert help in any of the above directions can feel confident in placing themselves in Mr. Duncan's hands.

**THE L. AND P. SUPPER.**—Thursday evening in last week found the members of the L. and P. in a rather frivolous mood, it being the occasion of the annual supper. A large party of members and friends gathered together, and voted the evening a big success. The following toasts were gone through: "The L. and P.," by Mr. Haddon (chairman); "The Visitors," by Mr. Charles Greenwood, who coupled with it the names of Mr. Date and Mr. Woodland, these two gentlemen afterwards responding; "The Press," by the hon. secretary, Mr. Ernest Human. Mr. Freshwater proposed the health of the chairman, which was taken with musical honours, and thus a pleasant evening was brought to a close at a late hour.

**ROYAL PHOTOGRAPHIC SOCIETY.**—The following are the two closing lectures to be delivered at the New Gallery:—  
Friday, October 23.—Autochrome lecture, "The Thames from Kew Gardens to the Sea." By J. McIntosh.  
Saturday, October 24.—"The Camera and the Sea." By F. J. Mortimer, F.R.P.S.

**THE RAJAR CAMERA,** offered monthly by Messrs. Rajar, 1907, Ltd., Mobberley, Cheshire, for the best print on "Rajar" P.O.P., has been awarded to H. Ridge, London Road, Newport Pagnell, his print having been judged the best sent in during September. The paper on which the print was made was purchased from Mr. Hogson, Church Street, Wolverton.

**LYCEUM CLUB PHOTOGRAPHERS.**—The photographers' section of the Lyceum Club held its first annual meeting on Friday, October 16, when the following members of the section were elected to serve on the Advisory Board for the coming year:—Mrs. George Arbuthnot, Miss Gertrude Bacon, Mrs. Bulstrode, Mrs. Aubrey Le Blond, Mrs. Carine Cadby, Miss Chadwick, Miss D'Espaigne Chapman, Mrs. Reynolds, Mrs. W. N. Shaw, Miss Lizzie Caswall Smith, Miss Susett Taylor, Miss E. L. Turner, Mrs. Victor H. Veley, and Miss Agnes B. Warburg.

**VICTORIAN PHOTOGRAPHIC AFFILIATION.**—The Victorian Photographic Affiliation's first open exhibition will be held in the Victoria Artists' Society's Galleries, Melbourne, in February next. The "Affiliation" is the governing body in connection with amateur photography in Victoria, all the leading clubs in the State being affiliated with it. Exhibits are being invited from England and other parts of Europe and from America, as well as the other States, and according to information received the committee have every reason to believe the exhibition will be a thoroughly representative one. Every care will be taken of the exhibits, and immediately on the close of the exhibition they will be returned to their owners.

**BOROUGH POLYTECHNIC PHOTOGRAPHIC SOCIETY.**—Mr. A. G. Buckham is now the hon. secretary of this society.

**THEFT OF PLATINUM FROM THE FRANCO-BRITISH EXHIBITION.**—After the public had left the Machinery Hall of the British section on Tuesday two ingots of platinum, technically known as "wire ingots," were stolen from the case of exhibits of Messrs. Johnson Matthey, and Co., of Hatton Garden. The following is a description of the property: Length, 20in. to 24in.; square section measurement about  $\frac{1}{16}$ in.; weight, about 100oz. troy each; value, £500 each, or £1,000 in all; exhibits insured by the owners. Immediately on the discovery was made the firm was notified. An examination proved

that, serious as the loss was, the owners had reasons for congratulation in the fact that a large ingot of platinum—weighing about 100oz. troy, and valued at £3,500—had not been taken. The firm supply practically the whole of the high-class dentists with platinum. The wire made from the ingots is used for the fastening of the more expensive false teeth to the plate, platinum being best able to resist the action of acids. The stolen metal, when once its outline is destroyed, will find a ready market. Indeed, but for the fact that they buy only from people of whom they have knowledge, it might have resold to Messrs. Johnson, Matthey, and Co. It will be, therefore, a difficult matter for the police to secure the criminals or the missing metal.

THE STORES COMMITTEE OF THE LONDON COUNTY COUNCIL has accepted the tender of Messrs. W. C. Hughes and Co., Brewster House, Mortimer Road, Kingsland, N., for the provision of lantern operators and accessories for the year. The estimated cost of the contract is £47 and a schedule of prices.

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.—At the annual meeting held on the 15th inst. the following programme was arranged for the twenty-fourth annual meeting, to be held at Canterbury in July next: Monday, July 5, morning and afternoon—around Canterbury; evening—reunion, presidential address, and annual general meeting. Tuesday, July 6—driving tour through the villages of Bridge, Patricbourne, Bekesbourne, Littlebourne, Ickham, Wickham, Fordwich, and Sturry; evening—papers, etc. Wednesday, July 7, morning—visit to the cathedral; afternoon—a garden party; evening—annual dinner and smoking concert. Thursday, July 8—excursion to Rochester; evening—papers, etc. Friday, July 9—excursion to Rye and Winchelsea; evening—papers, etc. Saturday, July 10—excursion to Maidstone. The headquarters of the convention during the week will be St. George's Hall.

ROVERS AND FREEBOOTERS is the way President Bradley, of the New York Photographers' Society, describes those photographers who go about the country picking up what work they can, and by means of cut prices taking business away from the man who settles down in a town and has to meet running expenses and taxes.

A "CHILD'S STUDY BOOK."—W. S. Ellis writes to an American contemporary: "This is simply an idea of mine, by which I utilise the balance of the proofs which I make for a customer; i.e., if a patron orders a dozen photographs from one negative of a child \$16 a dozen, 5 x 7, we will make a book of the balance of the proofs for them in platinum for \$10. Where there are eight or a attractive poses the proposition is very tempting, and as you see it gives us the opportunity of making prints from all negatives."

Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

MR. PONTING'S PHOTOGRAPHS AT THE R.P.S. EXHIBITION.

To the Editors.

Gentlemen,—As there seems to have been a disposition to regard the exhibit of Messrs. Raines and Co. at the New Gallery as a claim of a one-man pictorial show on my part I desire to disclaim any such intention, and should be glad if you would give me the opportunity of stating in your pages that I had nothing to do with either selection of the prints or the manner in which they are presented. Apart from knowing that Messrs. Raines desired to use some of my photographs, and had my consent to it, owing to absence from London I did not know what was being done, and was as much

surprised when I saw that their entire exhibit was from my negatives as to find that many of the subjects presented were from negatives made merely for illustrating my books and magazine articles, and, in my opinion, possessing little pictorial merit.

I should be glad to be clearly understood as to the object of my photographs. During my travels abroad during the last eight years I have been commissioned by certain American publishing companies to illustrate and write of the countries I visited. My work has thus been descriptive only, and under my agreement I had the privilege of doing but a limited amount of work for myself. For this work I do not claim any more than that it shows true phases of the Orient, and it has been my endeavour to introduce into it something of the local atmosphere and feeling.

At an exhibition of photographs which I was invited to give by the members of the Nobles' Club, Tokyo, the commendation that was there bestowed on my efforts to show something of the beauty and charm of Japan meant much more to me than the opinions of critics who have never seen the land. The approval of the foremost people in Japan was all I could ask for, but it took a practical form, and Baron Sonoda presented nearly 300 copies of my book, just then published, to the officers of the British Fleet who came to his garden party. These tributes, from a people among whom I have travelled for nearly three years, whose land I dearly love, and have visited no less than seven times, and have probably illustrated more than any other foreigner, I place a high value on indeed.
